He was very comfortable after the operation, complained of no pain and had a good appetite, but was allowed only liquid diet. The outer part of the dressing was overhauled the second day, but as it was perfectly sweet and free from urine the inner dressing was not disturbed. One week after the operation the dressing was changed, one of the sutures was removed and a small quantity of pus welled up from the wound. The drainage-tube which had been inserted could not be seen or felt. He was now rather restless at night and his temperature was a little raised. Three days later another suture was removed and the drainage-tube was found and taken out. His temperature at once fell and afterwards continued at normal. The discharge was very slight from the wound and everything progressed favorably. On August 5th, the wire hip-splint was left off, and on August 13th, the wound was completely healed. Considerable induration remained about the ring through which no distinct opening could be felt.

When he coughed the parts bulged out, but there was no descent of the hernia. He was now allowed to be up and about with a T bandage adjusted to keep up pressure over the ring. He was sent to the Convalescent Home August 17th, stayed there a month, during which time there was no descent of the bowel and was finally discharged September 17th. In October he was again admitted to the hospital with pneumonia, in which both lungs were involved. During the first night he coughed violently and the bowel was forced out for the first time since the operation.

Unfortunately the pneumonia affected a large part of both lungs and the child succumbed to the disease. The benefit following the operation in this case was very marked, and the hernia which had before been entirely beyond control was easily retained by a light bandage and did not come down even when this was removed.

He had quite a severe cough for some time before entering the hospital the second time, and it was only when the cough became excessive and the child was much weakened by the disease that the obstruction at the ring was finally overcome.

LIPOMA OF RAPID GROWTH, SIMULATING MALIGNANT TUMOR.

The patient was a boy, two years seven months old. The tumor appeared on the inside of the thigh close to the pubes a year and a half ago. It was seen by several of the surgeons of the hospital in consultation, one year ago; and at that time although of but six months' growth it was as large as an orange, of hard consistency, and apparently deeply attached among the adductor muscles. The opinion then prevailed that it was a lympho-sarcoma, and as the result of an operation seemed doubtful the parents decided against it.

Last spring, however, the mother took the child to some physician who applied caustics. The eschars which were made readily healed, and this fact led to the hope that the growth might not be malignant. The mother was accordingly advised to take the child again to the city for advice. Dr. Cabot, who now saw the child, found that the tumor although much larger was softer and less firmly fixed. He advised its removal, and the child entered the hospital June 2d, 1885. The tumor now extended from the pubes almost to the inner condyle of the femur; was elastic and indistinctly lobulated. On June 3d, the child was etherized and an incision was made down to the tumor extending from just below the os pubis nearly to the inner condyle. The tumor was easily dissected out with very slight hæmorrhage; a few bleeding points were tied. A drainage-tube was inserted at either end of the incision, the wound was irrigated with liquor iodæ chlorinatæ 1-20, the edges of the incision brought together with sutures, carefully dried and dressed with iodoform gauze. By bandaging the leg to an outside splint, compression was applied over the wound.

During the night the child was very restless, and despite the use of chloral slept but little. In the morning his temperature was 103.8°.

The dressing was changed and the wound found to be looking well with the exception of considerable œdema of the thigh, in consequence of which two of the stitches at the upper end of the incision were removed.

He continued restless and fidgety, seeming stupid and saying nothing. June 6th, the third day after the operation pus was found upon the dressing for the first time, and in the tubes were shreds of foul-smelling, fatty tissue. A large phenyle poultice was applied in place of the previous dressing. June 10th, four days later, there was a free discharge of pus from both ends of the wound, and the scar from the caustic had softened and was opened, a little thin fluid and pus escaping.

During this time the child was in a state of semi-consciousness; he recognized no one and had not spoken since the operation. His pulse was rapid and feeble, and temperature about 101°. The amount of urine was noticed to be diminished on June 6th; on the 8th a trace of albumen was found, and a week later granular and epithelial casts with renal epithelium were found. After the 10th, he slowly regained consciousness and would recognize his friends, protrude his tongue, etc. He seemed to understand what was said in the room. The wound continued to look well, discharging i-iiʒ of laudable pus daily. The discharge became very thick and increased in amount about the 18th. At the same time the upper third of the thigh became considerably swollen and had a hard indurated feeling: no fluctuation could be detected. This swelling continued to increase for nearly a week, when it slowly began to diminish, but it was several weeks before it disappeared. There was no perceptible difference in the amount or character of the discharge either with the increase or decrease in the swelling.

June 25th, his temperature rose to 104.2°, there was a slight blush about the wound and the discharge stopped, but there was no constitutional disturbance. The temperature came down the next day, the blush rapidly faded and the discharge again became free. From this time convalescence was rapid and uninterrupted. The discharge gradually grew less and had ceased by July 16th. The thigh slowly resumed its normal size, although considerable induration remained along the line of incision.

He went home July 16th, and since that time has been well.

The growth was a fatty tumor, but the lobules of fat instead of being large and distinct were very small and white and surrounded by a fibrous stroma, which gave to the cut surface much the appearance of a glandular tumor.

The rapidity of growth in this case was rather remarkable as was the marked change in the seeming character of the tumor, as it increased in size. At first, while buried between the muscles of the thigh, it was hard and immovable, while later, when it pushed its way up from among them, it was much softer and had considerable mobility.

PYÆMIA.

Albert D., admitted Saturday, June 20th. A strong, rugged boy. A week before while at play, he had fallen six or seven feet from a fence, striking on his side. He complained of soreness about the body on Sunday but went to school as usual on Monday. On Tuesday he became feverish, vomited and complained of pain in the neck and back; these symptoms continued and on Thursday he became delirious. His parents brought him to the hospital and he was admitted on the medical side, but no definite diagnosis was made. Numerous fine moist râles and patches of consolidated lung were found, which seemed to indicate a broncho-pneumonia, but there were also some of the symptoms of typhoid. There was a pustular eruption scattered over the body, most marked about the knees.

His condition remained unchanged for the first two days; he was actively delirious a part of the time, and nothing happened to throw any light on the case. On the third day, June 22d, the parotid gland on the right side began to swell and grow painful. Dr. Cabot now made a diagnosis of pyæmia, and the boy was transferred to the surgical side. On the following day the middle joint of the second finger of the right hand became swollen and painful, and the next day a swelling appeared in front of the left ankle. The swellings all rapidly increased in size, and fluctuation was soon found. They were all opened early. That of the finger communicated with the joint and contained thick fetid pus; the one at the ankle was more superficial, but extended five or six inches up the leg, necessitating two openings; this also contained thick and fetid pus. The parotid abscess contained thick laudable pus.

The delirium passed away, but the boy lay in a typhoidal state most of the time, taking brandy ʒi every three hours, and quinine gr.iii t. i. d. June 30th, the parotid on the left side began to enlarge, but this subsided under poultices, without forming an abscess. He remained in about the same condition until July 11th, when his right elbow suddenly became painful and swollen, and the next day a swelling appeared in the region of the submaxillary gland on the left. Both of these abscesses enlarged so quickly that they were ready for operation by the 13th.

The pus evacuated from the submaxillary region was extremely fetid. At the elbow, an incision was made on the outer side and a counter opening on the inner side; a drainage-tube was passed directly through the joint. The contents of this abscess was then seropus.

The boy seemed better and brighter after these two abscesses were opened. His stimulants had been increased to iv ℥ daily; this with eggs constituted almost all his food. He went on for about ten days without any set-back: the discharge from his numerous wounds was slight and he seemed to improve; but on July 24th, the right thigh was seen to be swollen posteriorly; three days later this was incised and a large quantity of pus was evacuated. There was no communication with the hip joint or the pelvis, as far as could be found. While he was upon the operating-table a swelling about the size of an egg opposite the lower dorsal vertebræ on the right side, was noticed. It was soft and fluctuating and could be made to disappear by pressure as though it were pushed within the cavity of the body. There were no symptoms connecting this in any way with the spinal canal. As it was evidently quite different from the other swellings, it was thought wise to aspirate it, and about ℥i of clear fluid, containing a few shreds of tissue, was obtained. This was sent to Dr. Gannett, who reported that it closely resembled cerebro-spinal fluid. It contained a small amount of albumen and some chlorides.

From this time the boy improved steadily. The discharge from all the abscesses rapidly diminished, and those which did not communicate with joints healed quickly.

By October 2d, he had gained strength enough to sit up. On the night of October 14th, he began to complain of pain in the left elbow, and in the morning it was found red, swollen and fluctuating. An internal angular splint was applied and the pain and swelling rapidly disappeared. In two weeks the splint was removed and all signs of trouble were gone.

The past month he has gained much in strength and is running about the ward. There is still a slight discharge from the elbow and finger, and from the submaxillary gland. The elbow has become anchylosed, and excision is proposed when he becomes stronger.

A CASE OF PARIS-GREEN POISONING.

SERVICE OF O. W. DOE, M.D., BOSTON CITY HOSPITAL.
REPORTED BY CHARLES E. TAFT, M.D., FORMER HOUSE-PHYSICIAN.

Michael K., was brought to the Boston City Hospital, May 24th, by friends who stated that he had poisoned himself.

The following history was obtained:

For some time his health had been poor and for the past few days his mind had not been clear. He had not been melancholic.

About six o'clock this morning, after drinking a cup of coffee, he went to a cupboard to get some licorice-powder which he had been accustomed to take for constipation. By the side of the licorice stood some Paris-green which had been recently obtained by the family to use about the place for vermin. As it was rather dark in the cupboard he did not notice the difference in the powders and took three or four teaspoonfuls of the poison.

The mistake was soon noticed and a physician sent for, but between one and two hours elapsed before he arrived. An emetic was then given and vomiting induced. His physician then ordered his removal to the City Hospital. Before arriving there he vomited several times and had some cramping of the muscles of the arms and legs. In all it was six hours and a half before he reached the hospital from the time he took the powder. He arrived there at 12.30.

Examination showed a man about sixty years of age and of rather poor nutrition. His temperature was very slightly subnormal, pulse 96, and of fair strength. There was no tenderness over the abdomen. Said he did not feel sick and there was certainly but very little in his aspect to indicate his condition. Said he had no burning sensation in throat or abdomen.

Very soon after entrance he vomited freely, the vomitus containing considerable greenish powder. A stomach-tube was introduced and the stomach was thoroughly washed out with warm water and warm lime-water. He vomited very freely while the tube was in his stomach. The vomitus appearing to be too thick, from the large amount of green tenacious mucous which it contained, to come away readily through the tube. Soon afterward he had a loose dejection containing some of the greenish powder. An enema of olive oil, suds and turpentine was given and two ounces of castor oil by mouth. The latter was almost wholly vomited.

He remained quite comfortable till 2 P.M., when vomiting commenced again. Dialyzed iron and the hydrated oxide of iron were freely given.

Now he began to look badly. His hands and feet were cold and his pulse was weak and increased in frequency. He complained of cramps in his legs and occasionally in his abdomen. Heaters were applied and abundant stimulation given. He failed steadily and died at 6 P.M., in a collapsed condition.

Autopsy sixteen hours after death by Dr. F. W. Draper: Brain rather moist. Few sub-pleural ecchymoses. Hæmorrhage into the lungs in many places. Subendo-cardial hæmorrhages. Hæmorrhages into both kidneys. The stomach contained considerable mucous and had extensive hæmorrhages, especially about the pyloric end. There was some Paris-green in the plyroic end of the stomach. Intestines contained Paris-green along the whole extent. There were no hæmorrhages into the intestines.

Two points in this case seem especially worthy of mention: the slight amount of abdominal pain, usually a prominent symptom in cases of arsenical poisoning, and the length of time which elapsed before the symptoms began. Until the character of the vomitus was seen, the absence of prominent symptoms after so long an interval, the strength and general appearance of the man made it seem extremely doubtful whether he had taken a fatal amount of Paris-green.

Reese, however, mentions a few cases where the symptoms were delayed from seven to sixteen hours after the arsenic was taken.

— The administration of very small frequently repeated doses of calomel, is recommended by Dr. Musser, of Philadelphia (*Therapeutic Gazette*), in the treatment of summer diarrhœa and vomiting of infancy. In severe cases he recommends a powder containing one-eighth to one-twentieth of a grain of calomel, combined with one-twelfth to one-fourth of a grain of Dover's powder, if there be much pain, fever, or restlessness. These ingredients, combined with a small quantity of powdered sugar, make a very minute powder, which is placed dry on the tongue, and washed down by a spoonful of water, with or without stimulant. He recommends that the dose should be repeated every half-hour at first.

Reports of Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

STATED meeting, March 25, 1886, the President, DR. J. C. WILSON, in the Chair.

INTRA-CRANIAL HÆMORRHAGE: RECORD AND CLASSIFICATION OF ONE HUNDRED AND FORTY-THREE CONSECUTIVE FATAL CASES OBSERVED IN MEDICO-LEGAL PRACTICE AND IN PRIVATE AUTOPSIES IN THE CITY OF PHILADELPHIA,

by DR. H. F. FORMAD.

Dr. Formad made some remarks on the different forms of intra-cranial hæmorrhages he had observed, and presented a number of specimens in illustration. There existed, he said, no well-defined descriptions of the various forms of intra-cranial hæmorrhages with reference to their etiology, and no classification that could be of any service in medico-legal examinations, and Dr. Formad suggested the classification and observations presented below as particularly adaptable for the latter purpose. These records may also be of some use to the surgeon who wishes to trephine. The observations were sufficiently numerous to warrant conclusions of importance for various ends. Dr. Formad regretted that he met his cases on the autopsy table only, and hence was unable to offer clinical details. In some cases the history was far from being reliable, and in a few the history was left to conjecture from the surroundings, the circumstances of the case, and the appearance and general lesions of the body. Dr. Formad wished to give credit to his colleague in coroner's work, Dr. R. R. Stewart, whose assistance in these observations he enjoyed, and also to his assistants, Drs. A. J. Plumer and George H. Chambers. Dr. Formad's cases of intra-cranial hæmorrhage embrace the results of kinds of head injuries (traumatic), and cerebral apoplexies (idiopathic hæmorrhages) as well. By the term cerebral apoplexy, he meant exclusively hæmorrhage in the brain, and did not refer to "congestive," "serous," "embolic," or "nervous," apoplexies, and other affections which tyrannic nomenclature has thrown together under the name of apoplexy.

Idiopathic cerebral apoplexy should also be strictly separated from traumatic cerebral hæmorrhage (this is not done by many writers). The latter can be further sub-divided into very well-defined sub-varieties of hæmorrhages, each etiologically distinct, as will be shown below. These observations will clearly show the necessity and usefulness of a classification such as suggested. There should never be any reasonable doubt at the post-mortem table as to whether a cerebral hæmorrhage was due to disease or to injury, or to both combined; nor as to whether a head injury preceded or followed an intra-cranial hæmorrhage. Dr. Formad believed that the diagnosis between the conditions just stated was much more difficult during life. He had seen errors made by foremost surgeons and physicians, and in the best hospitals in this city. Dr. Formad had seen cases of apoplexy diagnosed as fracture and trephined, and he had seen cases of fracture of skull unrecognized and untouched — left to die in the medical wards.

DR. FORMAD divided the cases of intra-cranial hæmorrhage observed by himself into the following eight different classes, the accounts being given here in abstracted form.

CLASS I: TWELVE CASES.

Post-mortem Appearance. One or more small hæmorrhages in the fasciculi teres in fourth ventricle; also ecchymoses in the lining of the other ventricles (no massive hæmorrhage anywhere); cerebral substance, as well as membranes, intensely congested. Cranium much congested; drops of blood oozing from cut surface and from periosteum all over. Marks of contusion in scalp, with more or less ecchymoses noted in all cases.

Histories. In two cases death was caused by electricity (details will be recorded elsewhere). Ten cases revealed histories of concussion of brain from injuries to head, without fracture of skull. Death was rapid or sudden from shock in all these cases. Six were males, and six females; the majority were young persons.

CLASS II: TWENTY-THREE CASES.

Post-mortem Appearance. Massive hæmorrhage (blood clot) of various sizes found between pia and dura mater; location, in the majority of cases, about opposite to place of application of violence. In none of these cases was this meningeal blood-clot located immediately beneath the point of application of violence. Ventricular ecchymoses also usually found. Brain anæmic in the majority of cases; whenever hæmorrhage large. Scalp injury well marked in some, in others less so, while in a few cases it was hardly noticeable.

Histories. Concussion from injuries to head, without fracture, in twenty-one cases; with fracture of skull in two cases. Death rapid (all within one hour) or sudden, either from shock or from compression of brain, the result of pressure from clot, or from both. Fourteen males, nine females; ages varied.

CLASS III: FORTY-FIVE CASES.

Post-mortem Appearance. Massive hæmorrhage (blood-clot) usually quite large; located between dura mater and inner surface of fractured skull, and at the site of application of violence only. Brain anæmic.

Histories in all cases revealed injuries to skull from accident, blows or other violence, resulting in fracture of skull. Death, on the average, ensued slowly from compression or anæmia of brain in the lapse of from several hours to several days (in few cases, from five to eight days). Thirty-eight males and seven females. Majority young and middle-aged persons.

CLASS IV: TWELVE CASES.

Post-mortem Appearance. Massive hæmorrhage, the same as in the preceding class, but occurring both at site and application of violence, and also on same point on the opposite site of skull; the first, a large clot, between dura mater and skull, while the latter, usually a smaller one, in the arachnoid (between dura and pia mater). At the side of the injury there was found a fracture of the skull in all these cases, so that they presented the combined features of Classes III and IV.

Upon the post-mortem table, however, there should be no difficulty in diagnosing such lesions at the present status of morbid anatomy as a distinct and well-defined science. After sufficient accurate observations have been made, and after seeing conditions repeat themselves, case after case alike, and having, in the majority of instances, cause and effect directly before the eyes, one should be enabled, in disputed cases, to make a post-mortem diagnosis which leaves but little room for doubt.

Histories in these twelve cases observed, showed injury to skull resulting in both fracture and concussion.

Death was nearly instantaneous in all these cases. Nine were males and three were females, mostly young and middle-aged persons.

CLASS V: NINE CASES.

Post-mortem Appearance. Punctiform and multiple hæmorrhages into the tissue of the dura mater which showed much thickening and adhesions to inner surface of skull from chronic pachymeningitis; great œdema of the pia mater. Brain congested, but no blood-clots in either ventricles or substance.

Histories in these cases revealed former attacks of sun-stroke or old injury of head. Death usually sudden and usually following a fall or severe intoxication and excitement. Ages of deceased between twenty and fifty; all males.

CLASS VI: THIRTY-FOUR CASES.

Massive hæmorrhage of various sizes into the brain substance proper, and thence into one or both of the lateral ventricles. Hæmorrhagic softening of brain substance of corpora strata or their vicinity. No meningeal hæmorrhage in any of these cases, though in some instances blood was observed to have leaked out from the inner ventricles through the transverse fissure and the fourth ventricle and some usually liquid (post-mortem) blood would be seen upon periphery of brain, in the fissures and within the meshes of the pia mater and the arachnoid. Brain substance in nearly all cases quite anæmic. Atheroma of cerebral vessels in all but three cases. Multiple small aneurisms of cerebral vessels noted in several cases. Chronic pachymeningitis in various degrees in all but five cases. In some cases there were scalp injuries from secondary falls; that is, falls that were the result of cerebral hæmorrhage. Many of these cases came under coroner's jurisdiction on account of suspicion of violence.

Histories wherever obtainable revealed either alcoholism, rheumatism or syphilis; middle or advanced age: twenty-six males, eight females. Death in the majority of cases ensued slowly. These are true cases of idiopathic cerebral apoplexy.

CLASS VII: SIX CASES.

Post-mortem Appearance. Massive hæmorrhage of various size, below pia mater, into brain substance, without breaking into lateral ventricles. In one case the blood-clot involved the substance of the pons and protruded into fourth ventricle; in two cases it occupied the substance of the right parietal lobe which was the seat of an abscess; in three cases the hæmorrhage was multiple, in small foci, with localized hæmorrhagic softening of periphery of brain substance in various places. In three cases there was atheroma and in the other three fatty erosions of the cerebral vessels. Chronic pachymeningitis in all cases. Brain substance congested.

Histories were those of former head injuries, alcoholism and probable syphilis. Death rapid, following intoxication or exertions. Age advanced in all cases; five men, one woman. Foul play had been suspected in all these cases.

CLASS VIII: THREE CASES.

Post-mortem Appearance. Massive meningeal hæmorrhage, below pia mater, combined with hæmorrhage into ventricles; no visible hæmorrhage into brain substance. Atheroma, and multiple small aneurisms of vessels of pia and of choroid plexus. Echymoses in scalp.

Histories of accidental falls. No previous symptoms of cerebral disease had been noted. Intemperate habits, injury of head leading to rupture of the diseased vessels, evidently had preceded the cerebral hæmorrhage. The persons were at work (washing) at the time, when nearly simultaneous with the concussion from the fall, death ensued. Both were women; ages fifty-seven and sixty-three years.

REMARKS AND COMMENTS.

A number of cases of intra-cranial hæmorrhage observed by Dr. Formad, he had excluded from the series above detailed. Several cases of compound comminuted fracture in which the skull, membranes and brain were partly pulpified into a mass and hence the hæmorrhage not being satisfactorily made out were excluded from the above records. He also excluded chronic cases of cerebral hæmorrhage and those resulting in abscesses or in a fatal lepto-meningitis or cerebritis after the patients had partly recovered from the immediate effects of the hæmorrhage. Dr. Formad did not incorporate into these records another large class of intra-cranial hæmorrhage, namely, that of infantile meningeal hæmorrhage. Of these he had seen many in coroner's work. Meningeal hæmorrhage is common in infanticides and fœticides; and even in still-born children. Dr. Formad could not plausibly explain the frequency of meningeal hæmorrhage observed in the still-born, otherwise than presuming that they were due to traumatic injuries from violence or to compression of the cranium during protracted labor or when forceps had been injudiciously applied. He did not meet with cerebral hæmorrhage in children, other than meningeal.

Returning to his classification, Dr. Formad stated that the quantity of the hæmorrhage or the size of the clot in any case of intra-cranial hæmorrhage appeared in all the cases he observed, to depend upon the duration or the time that elapsed from the moment of injury to death. In cases where death ensued rapidly or instantaneously from shock, as in many fatal cases of concussion, or even in fractures of skull followed by immediate death as in falls from a great height, the bulk of the ante-mortem hæmorrhage (the blood-clot) was remarkably small: or clots were occasionally entirely absent and only a post-mortem oozing of liquid blood could be observed. When death was protracted for several hours, then the blood-clot was usually large, weighing up to six or eight ounces, and causing death by compression of brain. In some cases of fracture of skull the hæmorrhage was probably delayed for several hours or ensues but very gradually.

Some patients are said to have walked around for many hours after the injury and subsequently when the blood oozed out in sufficient quantity to compress the brain, they fell, became unconscious and died in coma. In one case of this nature he had found a meningeal clot weighing eight ounces.

Dr. Formad observed that in the cases in which the intra-cranial hæmorrhage was voluminous and death instantaneous, there was very little scalp ecchymosis; whereas scalp hæmorrhage was more pronounced if the intra-cranial hæmorrhage was small and death delayed.

Further, Dr. Formad noticed that in no case where there was internal cerebral hæmorrhage, was there any meningeal hæmorrhage when cerebral vessels were normal; and in no case of traumatic meningeal hæmorrhage did he see any coincident ventricular hæmorrhage (except small echymoses) unless there existed some old lesion of the vessels or substance of brain. It appears, however, that blood from the lateral ventricles may leak through the foramen of Monroe into the third ventricle and thence by the aqueduct of Sylvius find its way into the fourth ventricle, but Dr. Formad did not see in any one of the cases he observed that a primary hæmorrhage into the fourth ventricle ever extended to the lateral ventricles, probably on account of its rapidly fatal character.

A hæmorrhage on the outside of an uninjured pia mater cannot reach the interior of the brain or the lateral ventricles.

The source of the hæmorrhage is often very difficult to determine. In fracture of the skull, the hæmorrhage is often diploic; in concussion of brain the hæmorrhage has for its source the vessels of the pia mater; in diseased conditions of the brain or in atheroma of vessels the small feeding branches of the middle cerebral and of the basilar artery bleed most frequently, and the blood breaking into the lateral ventricles forms clots, in either one or both of the ventricles.

The view expressed by Dr. J. A. Lidell in his large treatise on apoplexy (New York, 1873, p. 113) that "meningeal hæmorrhage not unfrequently occurs spontaneously, as well as in consequence of the operation of violent causes;" and that (see p. 120) "meningeal hæmorrhage of spontaneous origin is not a rare affection," is unquestionably erroneous. Yet such "*views*" are quoted by writers on forensic medicine and presented to juries in murder trials *as facts.* Ignorant or ill-informed post-mortem examiners can set murderers free, or on the other hand, can create unnecessary court trials.

CONCLUSIONS:

I. Hæmorrhage exclusively above the pia mater and above the dura mater, that is, on the outside of the brain, are always due to *traumatism* or to *sunstroke*, provided a cerebral source for hæmorrhage is excluded and the cerebral vessels and membranes were not diseased.

II. Hæmorrhage in the floor of the fourth ventricle is always traumatic, provided there are no blood clots in the lateral ventricles or any other part of the cerebral substance.

III. Hæmorrhage exclusively below the pia mater or in any part of the brain substance or in the ventricles (except the fourth), is always idiopathic, that is, is due to disease.

IV. There must be a diseased condition of the cerebral vessels or substance in order to ascribe a hæmorrhage to disease. There must be traumatism (a fall or violence) in order to account for a hæmorrhage in a normal brain.

V. The blood clot in concussion of the brain is not found at the point of application of violence, but always somewhere about the opposite side of the brain,

and always within the arachnoid, that is, between pia and dura mater.

VI. The blood clot in fracture of skull is always found at the point of application of violence immediately below and always between the dura mater and the fractured part of the skull itself.

VII. A blood clot formed within the cranial vault is more favorable to the patient if due to fractured skull than if due to a mere concussion.

VIII. Only clotted blood and infiltration of blood corpuscles into tissues indicate an ante-mortem hæmorrhage; liquid blood is due to post-mortem oozing, and only stains, but does not infiltrate tissues.

IX. Severe bruises and cuts of the scalp may be seen in cases of idiopathic apoplexy where a sudden cerebral hæmorrhage causes a person to fall.

X. In some cases it is impossible to decide by medical examination alone as to whether a head injury and the resulting hæmorrhage is due to a fall or to violence.

XI. External marks of violence may be invisible to the unaided eye in some cases of injury to the head or other parts; but are easily detected and distinguished from post-mortem spots by means of the microscope.

XII. The bulk of an intra-cranial hæmorrhage stands usually in inverse proportion to that of the external scalp hæmorrhage.

Dr. T. D. Dunn presented an unusual case of cortical hæmorrhage with rhythmical contractions of the left side of the body. A widow, aged seventy-three years, came under his care June 23, 1886, with the symptoms of congestive apoplexy. In a few days she recovered sufficiently to be able to leave her room. With the exception of some mental impairment for several months before the attack her health had been good. February 6, there was a second attack during the night, and when Dr. Dunn saw her there were regularly recurring movements of the left side of the body. Sensation and consciousness were not affected. The right side of the body could be moved at will, but articulation was impossible. The contents of bowels and bladder were discharged involuntarily. The movements continued during sleep. The movements gradually diminished, being lost in the leg on the fourth day and in the arm on the fifth. She died six days after the attack. At the autopsy a clot as large as a hen's egg was found situated on the right side of the brain very superficially extending from the ascending parietal convolution to the occipito-parietal fissure and from the convolution of the longitudinal fissure to the temporo-sphenoidal lobe. The convolutions pressed upon and partially destroyed were the ascending parietal, the convolution of the longitudinal fissure, the supra-marginal and the angular gyri.

ANOMALY OF HANDS.

Dr. F. A. Packard presented a patient having a congenital anomaly of both hands. The right hand consists of a thumb, an index finger and a little finger with only two metacarpal bones. The thumb has two phalanges and articulates with the same metacarpal bone as the index finger. The power of flexion is absent. The index finger has three phalanges. It can be flexed as a whole but the individual phalanges are fixed. The little finger has three phalanges. The left hand consists of a thumb, index, ring and little fingers with four corresponding metacarpal bones. The patient is one of five children. His mother and father are normally formed. One sister has one hand that resembles his left. Another has a left hand similar to his, and on the right hand has the middle and ring fingers united throughout their length. One brother has both hands similar to this man's left. The only member of his generation not deformed is his twin brother. He has several children, all normally formed, and so, too, with his nephews and neices.

CARCINOMA OF THE STOMACH.

Dr. J. M. Barton presented a tumor of the stomach removed from the body of a man, aged forty-seven years. His digestion became impaired two years ago, and soon afterward he noticed the tumor. The symptoms were mainly those of chronic gastritis, with at one time a profuse hæmorrhage. The tumor was hard and well defined, and occupied the epigastric region. At the autopsy the tumor was found occupying the upper portion of the pyloric outlet of the stomach and did not encroach enough on the outlet to prevent the ready passage of a finger. It was found on microscopic examination to be a scirrhus carcinoma.

THE AMERICAN GYNÆCOLOGICAL SOCIETY.

Eleventh Annual Meeting held in the hall of the Johns Hopkins University, Baltimore, Md., September 21, 22, and 23, 1886.

FIRST DAY. — MORNING SESSION.

The Society was called to order by the President, Dr. Thaddeus A. Reamy, of Cincinnati.

After the calling of the roll, Dr. H. P. C. Wilson, of Baltimore, delivered the address of welcome.

In the name of the resident Fellows, of the general profession and of the citizens of Baltimore and in the name of her women, he extended to the Society a hearty welcome. Were our hands as big as our hearts, the speaker said, we should kill you with kindness. Baltimore is ever ready and willing to welcome you whenever you are ready to come. I can assure you of the great interest which this community takes in the subjects of your deliberation.

The first paper was on

THE DIVISION OF THE CERVIX BACKWARDS IN SOME FORMS OF ANTEFLEXION OF THE UTERUS WITH DYSMENORRHŒA AND STERILITY,

by Dr. H. P. C. Wilson, of Baltimore.

This is an old subject. The operation from want of a judicious selection of the cases, by being done by unskilled hands in proper cases, by being done in unsuitable cases and from want of appropriate after-treatment this operation has been barren of good results in certain hands and followed by bad results in other hands. This operation has been substituted by the use of stems, sponge tents, and dilators, but I have found no measure so safe and efficient in the classes of cases to which I shall call attention, as the knife.

The classes of cases in which I would recommend the operation are:

First, Those of anteflexion of the uterus, with a hard indurated cervix, where the body is bent upon the neck, or the neck upon the body, forming a more or less acute angle.

Second, Those cases of acute flexion where the cervix is hyperplastic and indurated and dense as cartilage.

Third, Those cases where there is a hard unyielding internal os, through which the probe passes with difficulty and in its passage gives the sensation of passing over rough dense cartilage, while the finger in the sulcus between the body and the neck in front, gains the sensation of a strong cord tied around the uterus. This third class is frequently combined with the first, and often with the second. In a typical case calling for the knife, all these lesions co-exist. Nearly all these cases are sterile. In all of them the nabothian and utricular glands are hypertrophied and indurated.

The different methods of operating were then reviewed. If the patient escapes the secondary results which are liable to follow the use of tents, they are the most efficient means of overcoming the difficulty, next to the use of the knife. The forcible dilatation does not restore the anteflexed uterus. For the purpose of rectifying the difficulty, the knife is the surest means in the cases which have been referred to. Where the posterior lip of the cervix is divided and the internal os is divided anteriorly and posteriorly, the muscular fibres are paralyzed and the longitudinal fibres contract and tend to rectify the position.

The method of operation was then described. With the patient under an anæsthetic, the uterus is drawn downwards by a tenaculum in the anterior lip. The posterior lip is then divided with scissors up to the vaginal junction. An uterotome is next passed and the internal os divided anteriorly and posteriorly to an extent sufficient to permit the introduction of a large sound. The parts are allowed to bleed freely. A pledget of cotton soaked in a mixture of Monsel's solution, iodine and glycerine is then introduced into the cervix and over this pledgets treated with Monsel's solution and water and the vagina lightly tamponed. These are not removed until the third day. All manipulation of the uterus is avoided for at least two weeks. A sound is then carefully passed and every second day the os is gently stretched with a steel dilator. The patient is allowed to fully recover from the operation, which usually requires one month. Local treatment is then suspended for one month to allow the intra-uterine mucous membrane to improve. The patient then returns and applications of Churchill's tincture of iodine are made to the endometrium two or three times a week. The treatment after the lapse of a month is again suspended to be resumed in the course of one or two months. If this after-treatment is not carefully and properly carried out, the operation had better not be done. The speaker had performed the operation four hundred times, and had never obtained as good results from any other method. In no case has he had a death which could be attributed directly to the operation. If the patient is not disturbed by meddlesome after-treatment for ten days subsequent to the operation, there is not much danger of inflammatory troubles.

There are some cases of dysmenorrhœa and sterility where this operation is entirely unsuited. It was recommended only in the cases described in the beginning of the paper. Several illustrative cases showing the good effects of the operation in overcoming dysmenorrhœa and sterility were related.

DISCUSSION.

DR. T. A. EMMET, of New York. Fifteen or twenty years ago, I should have been willing to endorse all that has been said by the speaker. I think that I have done as much harm as any one by this operation. We must separate dysmenorrhœa and sterility as being due to widely different causes. Mechanical dysmenorrhœa, I believe to be a myth. We must also separate two conditions of flexion, one a flexure of the neck, a congenital defect, and the other a flexure of the body of the uterus due to preceding inflammation outside of the uterus. Sterility resulting from this latter cause is not relieved by the operation, and its performance is attended with great risks to life. The congenital flexion is the only one in which I operate to relieve the sterility. I do not operate for the dysmenorrhœa. There are a few cases of the inflammatory form of flexion where the operation benefits the reflex symptoms by its revulsive action.

In those cases where I have done the operation I have not left a raw surface but have drawn the vaginal mucous membrane to the bottom of the wound and secured it with stitches. This does away with the necessity for plugging and the fear of hæmorrhage.

This operative procedure is not free from danger. I have known of at least twenty deaths from it. If, as has been suggested by Dr. Wilson, all the effects of previous inflammation are removed, there is not the same danger, but I cannot see that the operation will do any good.

DR. JAMES R. CHADWICK, of Boston. I have not been successful with this operation in curing sterility or dsymenorrhœa. I regard the flexion as always congenital, the result of the persistence of the infantile shape of the uterus. This I am convinced is not confined to the anatomy of the organ, but also involves the function. The defect probably extends to other portions of the genital tract. The only cases in which I have had any results from operation have been where there is flexion with a small external os. In a certain proportion of these cases impregnation has followed the operation. I think that the operation should be restricted to those cases in which there is flexion with a small external os, but in which the uterus seems to be well developed in other respects.

DR. W. H. BAKER, of Boston. Some ten years ago, I saw a number of cases in which this operation was done, and while the immediate results were very gratifying, yet in many cases the patients did not retain these good results. The question arises, if this operation which was performed so frequently, was successful, would it not have lasted? It was found that in many cases, less severe measures would give equally good results. This has led to a clearer discrimination of the cases. Of late years I have limited the operation to the class of cases to which Dr. Emmet refers, in which there is a congenital malformation and those in which there has been an inflammatory condition, the results of which have been removed. The good results which Dr. Wilson reports must be explained by the great care in the after-treatment which he practices.

DR. FORDYCE BARKER, of New York. Some thirty years ago I saw Simpson perform this operation a number of times. He performed it in his office and did not seem to apprehend any danger from hæmorrhage. I employed the operation in a few cases, but

I soon gave it up. The only cases in which I employ it is where the narrowing is at the os externum.

Dr. J. Scott, of California. I have practised the operation, but while the immediate results have been good, I have been disappointed in the ultimate results. I have gradually come to limit the operation to the cases described by previous speakers. After the operation, the patient should be confined to bed at perfect rest, and hot water injections be employed every two hours.

Dr. W. T. Howard, of Baltimore. I have given all the operations alluded to a fair and full trial. My experience has not shown me that any particular operation is the one for all cases. By the antero-posterior incision, I have had some excellent results. With the precautions adopted in operating in other portions of the body, an incision of this kind, in the majority of cases, should not be dangerous. Dr. Mundé, in a paper on this subject, reports over three thousand cases, with only nine deaths. I think that forcible divulsion is attended with as much risk as incision. In my practice, the method adopted has varied according to the case. In some I have employed the posterior incision, in others the bilateral incision, but, in the majority of cases, I dilate, using antiseptic precautions, and never taking less than twenty to thirty minutes to complete the operation.

Dr. H. P. C. Wilson, of Baltimore. I have not heard anything in the discussion to convince me that, in properly-selected cases, division of the cervix is not the best thing to do. As I have already said, if the operation is not followed by proper after-treatment, it had better not be done. The danger is not from the operation itself, but from the improper after-treatment.

ANOTHER MODIFICATION OF EMMET'S CERVIX OPERATION, WITH A CASE IN POINT,

by Dr. B. Stansbury Sutton, of Pittsburg.

A case of old-standing neglected double laceration of the cervix was reported. The cervix was composed of dense, hard, hyperplastic tissue, almost cartilaginous in character. An operation by the ordinary method was out of the question, for the sutures would not have held. In order to overcome the greatest amount of cicatricial tissue and remove the condition, the following procedure was resorted to: The lower lip of the laceration was denuded of its altered mucous membrane, leaving only a narrow strip, corresponding to one-half of the strip usually left to serve for the future os; the upper lip was treated in the same way, leaving the opposite half of the strip of mucous membrane. When the flaps were brought together, the strips of mucous membrane lay side by side, with the undenuded surface of one flap in apposition with the denuded surface of the opposite flap. In this way, union in the position of the future canal was prevented. Good union followed the operation, and at the end of three weeks a Simpson sound was passed without difficulty. This operation may be of service in certain cases where the usual operation cannot be performed.

DISCUSSION.

Dr. Thomas A. Emmet, of New York. The modification seems to be an ingenious one, but its value can only be determined by future trial. In such cases, however, where there has been such cystic degeneration, it is often better surgery to amputate a portion of the cervix, so as to get into healthier tissue. In a certain number of cases, I have always performed amputation. I have always objected to amputation of the cervix in so-called elongated cervix. I use the term in the sense in which it is employed by the Germans. If we remove the tissue to a depth below the follicles, the remaining dense tissue will gradually soften. I do not mean to amputate to as great a depth as the dense tissue extends.

Dr. George J. Englemann, of St. Louis. I have found no difficulty in preventing union, and I have paid very little attention to the strip of mucous membrane. I have, in such cases, as has been described by Dr. Sutton, cut away nearly all the mucous membrane, and inserted a short piece of fine catgut. This keeps all the opening which is necessary. When, however, we come to such extreme cases, I think that it is better not to attempt what has been termed Emmet's operation, but to resort to partial amputation, as is performed in Germany.

Dr. W. H. Baker, of Boston. I think that if we can restore the healthy character of the strip of mucous membrane and retain it, that is the best surgery. In this class of cases, I have been in the habit of removing a transverse wedge-shaped portion of each lip of the cervix, and then bringing the parts together. In this way, the hyperplastic tissue preventing the apposition of the surfaces is removed. If proper preparatory treatment is employed, I think that the saving of the strip of mucous membrane can be accomplished.

Dr. R. Stansbury Sutton, of Pittsburg. In the case described, there was only one of two things to be done — either to remove the cervix, or devise some new method of operating. This modification gave complete satisfaction in this case, and I purpose trying it in other similar cases.

In the absence of the author, the following paper was read by the Secretary:

NOTES ON THE TREATMENT OF RECENT LACERATION OF THE CERVIX UTERI,

by Dr. Elwood Wilson, of Philadelphia.

Occasionally a tear of the cervix can be recognized immediately after labor, but sometimes this cannot be done. The patient should always be examined ten or twelve days later. If laceration be found immediately after labor, injections of corrosive sublimate solutions, one to five thousand, with the insertion of an iodoform suppository, should be resorted to. The vagina should be irrigated every other day, and the suppository renewed. When the laceration is found within three weeks after delivery, the following treatment should be employed: After the surface has been carefully cleansed and dried, it should be painted with a solution of nitrate of silver, one drachm to the ounce of distilled water. From three to five applications, at intervals of five days, are usually required. In every case in which the author has tried this measure (six in number), the result was entirely satisfactory.

DISCUSSION.

Dr. Fordyce Barker, of New York. It seems to me that the practice recommended in the paper is better worthy of trial. It is much preferable to the rule laid down within the past few years, that if there is a laceration it should be closed immediately after labor. If this method will effect union it should be tried.

Dr. Thomas A. Emmet, of New York. I suppose

that a certain amount of laceration occurs in every labor, but it is wonderful what nature will do to restore the cervix where septic poisoning is not present. It seems too, that in all cases where, under favorable circumstances, nature has failed to repair the damage, there have been symptoms indicating septic inflammation. In the cases reported I believe that the same results would have been obtained even if nitrate of silver had not been employed.

DR. J. SCOTT, of San Francisco. In only one case have I attempted to sew up the cervix shortly after labor. In this case there was an extensive tear of the cervix and of the perineum. There was considerable bleeding, and five hours after labor I thought it advisable to sew up the cervix. The tissues were so soft that it was with the greatest difficulty that I could get the sutures to hold. Union took place, however, both in the cervix and in the peritoneum.

AFTERNOON SESSION.

The first paper was entitled,

PELVIC INFLAMMATION; CELLULITIS, VERSUS PERITONITIS,

by DR. THOMAS ADDIS EMMET, M.D., of New York.

In this country the term cellulitis has come to signify pelvic inflammation, without reference to the special form, but its origin is supposed to have been in the connective tissue. So close is the relation between the connective tissue and the peritoneum, that it seems impossible for inflammation to be present in one without affecting the other. There are situations, however, as between the uterus and bladder, and between the uterus and rectum, where cellulitis might exist without involving the peritoneum. Inflammation in these situations tend to resolution, and so the tissues soon regain their healthy condition if suppuration does not take place. After septic poisoning, the peritoneum rapidly becomes inflamed and adhesions occur, the circulation in the bloodvessels becomes more or less obstructed, and the actions of the absorbents is greatly impeded. Finally a condition is produced which remains long after the symptoms have subsided, and one not prone to change or amenable to treatment. In such cases a fresh attack is provoked by slight causes.

It has been objected that when the abdominal cavity is opened for the removal of the ovaries, very slight evidences of inflammation are found. In a recent case, I expressed the opinion from the vaginal examination that a thickened and shortened left broad ligament would be found at the operation. No broad ligament was found, but there was an enlarged tube lying against the side of the vagina. Similar cases have been noted. I should explain these cases in this way. If there is an inflammation between the folds of the broad ligament, it must involve the peritoneum. As a result of the inflammation, the connective tissue disappears and adhesion of the opposing surfaces takes place. The broad ligament is flattened out so that Douglass' cul-de-sac disappears on that side. The vaginal wall is raised up so that it and the tube lie in contact. This is the condition found by the surgeon when he operates for the removal of the diseased fallopian tubes. In all these cases I feel satisfied that there has been inflammation of the connective tissue. I think that the inflammation has been secondary to the cellulitis in every instance except where the primary inflammation was the result of gonorrhœa. If my observations are correct they would prove that the connective tissue never regains its integrity after having been once inflamed. If the surrounding tissue has restored the loss the part will return to its normal condition. If the loss cannot be replaced, nature can only repair the injury by a process of adhesive inflammation of the parts involved.

I have used the term thickening of the broad ligament, but I have not meant to imply that there is a deposit of lymph between the layers of the broad ligament. The enlargement is, I think, due to the dilated state of the veins. The condition is one easily aroused to activity.

It is still a moot question as to the way in which the tube has become involved where gonorrhœa is not the cause of the inflammation. In septic poisoning after surgical injuries, I believe that the connective tissue of the veins and lymphatics first become involved and that the inflammation of the peritoneum is secondary. There is no evidence to prove that the inflammation passes into the uterine canal and thence to the tube, except in such cases where the process is due to gonorrhœa.

The prognosis as to the result to be gained by local treatment is doubtful in those cases due to gonorrhœa, in those cases where the pelvic inflammation is of long standing, without reference to the cause, and in those with a history of frequently recurring attacks. In cases which can secure every attention a cure by local treatment can sometimes be effected, but a long time is required. In cases which have to gain their own living, we may seriously consider the advisability of an operation after having gained the consent of the patient after a true representation of the operation and its results. We should enter a protest and the profession should demand a recognition of the responsibility of those who are indiscriminately operating for the removal of tubes and ovaries. It requires an expert to determine when the operation is necessary, and still more experience and skill to do it with safety to the patient. It should only be done as a last resort after other measures have failed. In a number of cases in private practice I have succeeded in restoring the patient to health by local treatment, for whom the operation had been strongly urged. If we could get accurate statistics I think that it would be shown that the average amount of benefit gained does not compensate for the amount of risk. I believe that the operation is done too often even by those who have the least death-rate. I predict that five years will not pass before it will be almost necessary to offer an apology when this operation is proposed.

DISCUSSION.

DR. ROBERT BATTEY, of Georgia. From my experience it has seemed to me that the pelvic cellulitis which gives so much trouble, was in a large proportion of these cases secondary. So far as disease affecting the tubes is concerned, I believe that if we throw out of consideration the gonorrhœal cases, the primary disease starts in the ovary. I regard most of these serious inflammations of the pelvic cellular tissue as dependent upon cystic or cirrhotic disease of the ovary.

With reference to the frequency with which this operation is done, I must confess that I am largely in sympathy with the speaker. I think that the opera-

tion is done too often. I do not believe that every case of organic disease of the ovary requires operation.

In reply to a question of Dr. Fordyce Barker, asking him to state the grounds on which he would advise removal of the tubes and ovaries, Dr. Battey said that every case must be determined for itself. If I had a poor miserable patient, without the means of comfortable subsistence, suffering with ovarian or tubular disease, I would operate. If I could put such a patient under suitable surroundings and under a prolonged course of treatment, I might not think of the knife, but we have to look at the cases as they exist. I do not require in my cases an absolute diagnosis of disease of the tubes or ovaries prior to operation. It is sufficient for me to know that the general health is broken down by reason of the perverted function of her ovaries, that she is utterly miserable, that there is no reasonable hope of restoration to health by other means, and that there is a reasonable prospect of restoration by removal of the ovaries. Under such circumstances I unhesitatingly operate, and contrary to my former view, I do find that the ovaries are diseased.

DR. R. STANSBURY SUTTON, of Pittsburgh. I believe that when the ovary is diseased and cannot be cured by ordinary means, when it is interfering with the health of the woman and her duties in life, it should be removed. If the ovary is diseased and is a burden to the woman it is as much the duty of the surgeon to remove that ovary as it is to remove a diseased eye-ball. I agree that the operation is being done too often, not, however, by competent men, but by incompetent men.

The conditions which require the operation are not always clearly understood before the abdomen is opened. I do not believe that a man is compelled to be positively certain of what he is going to find before operating. The speaker then presented several specimens and described the cases from which they were removed.

DR. BUSEY, of Washington. I think that if pathologists will return to the histological basis, there will not be the difference of opinion which now exists. I believe that it is now held that the cellular tissue is really a vast lymphatic structure and that the peritoneum is a large lymphatic sac. Instead of discussing nice distinctions between pelvic cellulitis and pelvic peritonitis, it would be better to classify as pelvic lymphangitis, these different varieties.

DR. J. SCOTT, of San Francisco. I might mention some of the cases bearing upon this point which I have seen. One was a patient supposed to have fibroid tumors. The abdomen was opened and both ovaries found to contain pus. They were removed and the patient recovered. In a second case the patient presented a tumor in the right side. The temperature record was kept for two months, during which time it did not vary half a degree. On opening the abdomen, the ovary was found to contain ten ounces of pus. The right ovary was removed, but the left appeared to be healthy and was left in position. During the operation the bladder was opened. This was sutured and the patient made a good recovery. Five weeks later the patient complained of pain in the left side, and on examination, I found an enlarged left ovary; this was removed and the patient promptly recovered. In a somewhat similar case, one ovary was removed. In a short time the other enlarged, but the operation was postponed and the woman died of rupture of the abscess.

DR. MATTHEW D. MANN, of Buffalo. I wish to allude to the possibility of one tube and ovary being diseased without involvement of the other. There is no reason why it should be so; I have in several cases where the disease appeared to be limited to one side, removed but one ovary and the result has been a perfect cure. This operation avoids some of the objections urged against the removal of both ovaries.

DR. H. P. C. WILSON, of Baltimore. I believe that where there is a general cellulitis, there is more or less pelvic peritonitis. These two affections are often associated. In the early stages, the inflammation is often controlled by active treatment. If it is not controlled, it may go on to the formation of abscess. The pus may be discharged and the patient recover. Occasionally the abscess occurs in the tube or ovary and these are the cases in which laparotomy is often called for. I agree that the operation is done too frequently. The point which Dr. Mann has raised that it is not always necessary to remove both ovaries, is a very important one.

The officers for the ensuing year are as follows: *President*, Dr. A. J. C. Skene, of Brooklyn; *Vice-Presidents*, Dr. John C. Reeve, of Dayton, O., and Dr. Elwood Wilson, of Philadelphia; *Secretary*, Dr. Joseph Taber Johnson, of Washington; *Treasurer*, Dr. Matthew D. Mann, of Buffalo; *Council, additional Members of*, Drs. W. H. Baker, of Boston; C. C. Lee, of New York; T. M. Trysdale, of Philadelphia; and A. Reeves Jackson, of Chicago.

The following new members were elected:—Drs. Charles M. Green, of Boston; A. F. A. King, of Washington; E. C. Dudley, of Chicago; A. W. Johnstone, of Danville, Ky.; J. E. Janvrin, of New York; H. Marion Sims, of New York; I. F. Baer, of Philadelphia; and W. Gil Wylie, of New York.

It was decided to hold the next meeting in New York, beginning September 15th, 1887.

A communication with reference to the organization of a Congress of American Physicians and Surgeons, was presented.

Dr. John C. Reeve, of Dayton, O., offered the following:

Resolved, That this Society expresses an opinion favorable to the formation of the proposed Congress, but that the committee be instructed not to favor any plan looking towards a surrendering of its distinctive title character, or to interfere with the full and entire management of its own affairs in every respect.

The following amendments were offered and accepted.

(1) That this Society does not favor meetings of the Congress oftener than biennially.

(2) That the committee opposes, as far as possible, meetings in the month of June.

Resolution as amended adopted.

The committee consists of Drs. Samuel O. Busey, of Washington; Fordyce Barker, of New York; T. A. Emmet, of New York; James R. Chadwick, of Boston; and Joseph Taber Johnson, of Washington.

(To be continued.)

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 30, 1886.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., *Boston. Price, 15 cents a number; $5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.

283 WASHINGTON STREET, BOSTON, MASS.

CEREBRAL INFANTILE PARALYSIS.

STRUMPELL[1] reported two years ago twenty-four cases of cerebral infantile paralysis, in children from four weeks to six years old. The affection comes on without known cause, attacks healthy children, and resembles very closely acute spinal paralysis, anterior poliomyetitis. There is an initial stage of fever, with vomiting, diarrhœa and convulsions. After this stage has passed away complete hemiplegia is discovered.

It is questionable whether the affection is ever fatal, but he suggests that this may be the cause of some of the fatal cases of convulsions and severe cerebral symptoms in children. The hemiplegia seldom remains complete; the child finally becomes able to walk, although it may go with a limp, but the arm remains more paretic and loses its power for finer movements. The paralysis is not as complete as in some cases of spinal paralysis. Paralysis of the lower muscles of the face and strabismus have been observed in rare cases. There may be menoplegia, or merely ataxia. The growth may be arrested, but there is never degenerative atrophy or reaction of degeneration. There are distinct muscular tension, contractures, and increased patella reflex, the latter being also seen on the sound side. Some children remain epileptic. Athetosis and associated movements are quite common. Sensibility is but little affected. Some children have disturbances in speech, and a few show distinct mental impairment. He considers that the gray matter of the cortex is attacked, and says that in some cases parencephalic defects have been found in the brain, with traces of former inflammation. He suggests that the disease may have an infectious origin.

Ranke[2] has recently reported nine cases in his own experience, in some of which he had made careful electrical examinations, finding a quantitative diminution of excitability, but never reaction of degeneration. In regard to other symptoms his observations agree precisely with Strümpell's.

Bernhardt[3] also reports eighteen cases, some of which were connected with a previous infectious disease. The symptoms agree for the most part with those described by Strümpell. He notes, however, that the hemiplegia follows on the convulsed side, or the most convulsed side if the convulsions are bilateral. Some children became absolutely dumb, or said only yes and no, although the hearing was perfect. All forms of aphasia in children, whatever their cause, pass off completely as a rule. In not a few cases of spastic hemiplegia the intelligence suffers; there are vertigo, epileptic attacks, a change in the emotional state, moral perversity, etc. In his cases the patellar reflex was not much increased on the paralyzed side. Associated movements are commoner because the basal ganglia are unaffected, and the impulse from the sound side can pass through the corpus callosum to them, reaching the still healthy tract below, while the disease checks the inhibitory action of the cortex on the affected side.

Other causes, however, may produce hemiplegia in a child, and are to be diagnosticated as in the adult. If, in a healthy child, we see unilateral and persistent convulsions, followed by hemiplegia, contractures, hemichorea, hemiathetosis, associated movements, etc., we may speak of a definite clinical type of disease, cerebral infantile paralysis. The process may be bilateral, with depression of the cortex, and it may be the cause of some cases of idiocy. It is not a poliencephalitis, as the cortex is not alone affected; furthermore, that is a name which Wernicke has previously given to degeneration of the nuclei of the oculo-motor nerves in the pons, leading to external ophthalmoplegia. It may be distinguished from acute anterior poliomyelitis by the presence of convulsions, fever, hemiplegia, facial paralysis, a normal or exaggerated patellar reflex, contractures, associated movements, aphasia, anasthria, dementia, and a change in character. There is also less atrophy and less defect in the development, and merely a quantitative diminution in the electrical excitability without reaction of degeneration.

In this connection, it may be of interest to refer to a case reported by Brinswanger.[4] The patient was imbecile and epileptic, and had attacks of maniacal epilepsy. The right arm was paralyzed and atrophic. The examination of the brain, which was very thorough, showed a parencephalic defect in the left side of the brain, involving the third (inferior) frontal, the lower and middle thirds of both central convolutions, the lower parietal (the supra-marginal and angular gyri), the first temporal, and the insula. The patient could talk a little, and this power, it was thought, might be due to the action of the right hemisphere.

FAITH HEALING AND KINDRED PHENOMENA.

Under this head, Rev. J. M. Buckley, D.D. a clergyman of the Methodist Episcopal Church, writes for the *Century Magazine*. These are his "inductions" from an exhaustive survey of the facts:

(1) That subjective mental states, as concentration of the attention upon a part, with or without belief, can produce effects either of the nature of disease or cure.

(2) Active incredulity in persons not acquainted with these laws, but willing to be experimented upon, is often more favorable to sudden effects than mere stupid acquiescent incredulity. The first thing the incredulous, hard-hearted man who believes that "there is nothing in it," sees that he cannot fathom, may lead him to succumb instantly and entirely to the dominant idea.

(3) That concentrated attention, with faith, can produce very great effects; may operate powerfully in acute diseases, with instantaneous rapidity upon nervous diseases, or upon any disease capable of being modified by direct action through the nervous or circulatory system.

(4) That cures may be wrought upon "diseases of accumulation," [sic] such as dropsies and tumors of various kinds, with great rapidity, where the increased action of the various excretory functions can eliminate the accumulations from the system.

(5) That rheumatism, sciatica, gout, neuralgia, contraction of the joints, *and certain inflammatory conditions* (?) may disappear under similar mental states suddenly, so as to admit of healthful exercise, which exercise, by its help upon the circulation, and through it upon the nutrition of diseased parts, may produce a permanent cure.

(6) That the "mind cure," apart from the absurd philosophy of the different sects into which it is already divided, and its repudiation of all medicine, has a basis in the laws of nature. The pretence of mystery, however, is either honest ignorance or consummate quackery.

(7) That all are unable to dispense with surgery, where the case is in the slightest degree complex, and mechanical adjustments are necessary; also that they cannot restore a limb, or eye, or finger, or even a tooth which has been lost. But in certain displacements of internal organs, the consequence of nervous debility, which are sometimes aided by surgery, they all sometimes succeed by developing latent energy, through mental stimulus.

Rev. Dr. Buckley concludes his article with the following words:

"That faith healers represent God as interfering constantly, not by cause and effect in the order of nature, but effecting the result directly. Their want of superiority to those who are not Christians, but use either false pretences or natural laws, condemns their pretentions. . . .

"Faith cures, technically so called, as now held by many Protestants, is a pitiable superstition, dangerous in its final effects. It may be asked, what harm can result from allowing persons to believe in 'faith healing?' Very great indeed. Its tendency is to produce an effeminate type of character, which shrinks from any pain, and to concentrate attention upon self and its sensations. It sets up false grounds for determining whether a person is, or is not, in the favor of God. It opens the door to every superstition, such as attaching importance to dreams, signs, opening the Bible at random, expecting the Lord to make it open so that one can gather his will from the first passage one sees, 'impressions,' 'assurances,' etc.

"Practically, it gives great support to other delusions which claim a supernatural element. It greatly injures Christianity by subjecting it to a test which it cannot endure. It directs attention from the moral and spiritual transformation which Christianity professes to work — a transformation which, wherever made, manifests its divinity, so that none who behold it need any other proof that it is of God. It destroys the ascendency of reason in the soul, and thus, like similar delusions, it is self-perpetuating, and its natural, and in some minds, its irresistible tendency is to mental derangement.

"Little hope exists of freeing those already entangled, but it is highly important to prevent others from falling into so plausible and luxurious a snare, and to show that Christianity is not to be held responsible for aberrations of the imagination, which belong exclusively to no party, creed, race, clime, or age."

Having given at some length the Rev. Dr. Buckley's view of mind curing, faith healing, etc., we are glad to quote from the most recent book by a prominent apostle of "mind curing," Mr. W. F. Evans, author of "Divine Law of Cure" and "Primitive Mind Cure," who treats his subject this time under the title of "Esoteric Christianity and Mental Therapeutics."[1] From this treatise we learn that,

"The fundamental principle in the practice of the phrenopathic method of cure is the recognition of the true idea of man as already in his true being an immortal spirit, and as such, exempt from sin and disease. In our conception of the patient we divest him of the material and astral envelope, and think of him not as about to be saved in some future time, but as *already saved*, so far as his true being is concerned. We, as it were, dematerialize him in our idea of him. Through the influence of mind upon mind, and in accordance with the law of thought-transference, this serves to dispossess him of the idea and belief of disease, and free him from his engrossment by the illusions of sense. It may be objected to such a method of mental cure, that it is too transcendental, and but a few are sufficiently unfolded spiritually to practice it with any degree of success. In reply we would only say that the intelligent force which creates and governs the world is transcendental; that is, it is purely mental and is beyond the grasp of the senses, but is none the less real and potential for all that. It is quite true that only a small number of persons are at present qualified to practise the system with marked success. But it has been our aim to educate men and women up to that degree of spiritual development that will greatly increase the number of successful practitioners. It may, in truth, be said of surgery, that only a small fraction of the twelve hundred millions of the human race are qualified to be eminently skilful surgeons. Yet that is no weighty objection to the modern science of surgery which is accomplishing such marvels in saving life. The good surgeon, like the poet, is born, not made. The same is true of the phrenopathic healer.

"In order to a successful practice of the mental-cure system, it is not necessary to deny the personality of God as some have done, and reduce him to an inconceivable sea of being, an ocean of spirit without bottom or shore. . . . Neither is it necessary to deny the personality and persistent individuality of the human spirit. Personality is not predicable of the body, for, as we have shown, the corporeal organism is not man. The mind or thinking principle is the man. . . . It is not necessary to deny the existence of matter, but only to affirm the sovereignty of mind over it. Matter exists as a mode of consciousness in us, and is as real as that mode of thought. So disease exists as a wrong way of thinking, and to change that way of thinking for the belief of the truth, is to cure disease of whatever nature it is. It is not necessary to tell a man, dying of consumption, that he is not sick, for that is not true. If he is not sick, why try to cure him? We would only affirm, and to

[1] H. H. Carter & Karrick, Boston, 1886.

possible, cause him to perceive, that the deepest reality of the disease is not physical but mental. By a fall on an icy sidewalk a man may break his arm or his leg. We would not cure him by denying the fact of his existence, or of the sidewalk, for there is no saving virtue in what is false. But recognizing both the fall and the fracture, we would affirm that the immortal man is not injured, and that no sooner was the wound made than an everywhere-present Divine Life goes to work to heal the hurt." [Sometimes with shortening and deformity.] "We would steadfastly believe this, and form in our mind the idea of the change to be effected in order to a cure, and aid nature by accelerating the curative process.

"To modify a patient's thinking in regard to himself and his disease, we employ the principle of suggestion or positive *affirmation* — not mental argument, as it is sometimes called, for argument creates doubt and reaction. No sick man was ever cured by reasoning with him, mentally or verbally. It is the business of the man who *knows* the truth, not to argue, but to affirm. . . . But the effect of suggestion is the result of the *faith* of the subject, for it is always proportioned to the degree in which the patient *believes* what you say. If the patient is disposed to believe you, the magnetic state is not necessary to the influence of your affirmations upon him. If he is not thus disposed, we employ silent or mental suggestion, and oftentimes with marvellous effect. In accordance with the law of thought-transference, and acting on the principle that ideas operate as causes, we form in our minds the idea of the change to be effected in the patient in order to the cure of disease. . . . In dropsy there is a suspended or defective action of the kidneys and sometimes of the skin. A cure cannot be effected by any therapeutic agent without a restoration of the kidneys to their normal functional action. In rheumatism there is also a defective action of the renal functions. Certain acids, as the lactic, the uric, and lithic acids are retained in the blood instead of being eliminated from it by the kidneys.

"In some cases of disease an increased or diminished action of the perspiratory glands of the skin is indicated as necessary, or an increased activity of some one or all of the excreting organs. Whatever the physiological change is which is demanded, the universal life-principle, which we call nature, is making an effort to effect it, and we may augment her curative endeavor by forming in our minds the idea of the change. Here knowledge is power, and we find medical science an auxiliary to the mental system of cure. And we would take occasion to remark, that no *intelligent* practitioner of the mind-cure will ignore wholly [*sic*] all medical science. Mind is the only active principle in the universe. The mind of a skilful surgeon performs marvels in saving the lives of people."

On still another page we are told that

"He who carefully studies that development of Christianity which we have in the writings of Swedenborg will find all the truth there is in the various schools of mental cure. . . . In the revolving wheel of life the early Christian method of cure by faith, and which through the prevalence of materialism and sensualism has descended to the bottom of the circle, is now coming uppermost again under the name of phrenopathy or mind-cure.'"

Thinking that some of our readers might still be curious about the mind-cure, which has, during the last year or two found its devotees, especially here in New England; thinking moreover that their conception of the system might possibly still be a vague one, and realizing that we ourselves were under a certain degree of bondage to the "dominant scientific materialism of the day," that we had not come to the perfect "knowledge of the real self, the immortal and undying Ego, the unchanging *I Am*," we have endeavored to draw enlightenment from passages found on the latest pages of a writer of a series of works on "Mental Therapeutics;" a practitioner who has used the principles he expounds for nearly a quarter of a century, principles which, he assures us, "may be viewed as established rules in the phrenopathic method of cure."

Should any of our readers suspect that the "thread of his verbosity is drawn out finer than the staple of his argument," we fear we can be of little further use to them.

THE POISONING OF A FAMILY BY "ROUGH ON RATS."

THE dangers incident to the at present unrestricted sale by grocers and others of white arsenic, in the form of "Rough on Rats," and the common use of this powder, thus placing it ready at hand for use by any evil-disposed person, was well illustrated in the case of the Blanchard family of Wilmington, an account of whose experiences has lately been published in the daily journals.

As it appears from the testimony given at the hearing before the court, the colored maid, of about fourteen years of age, who set the table for tea that evening, had been reproved by the mistress during the day for some neglect of duty. Of the seven persons who partook of the meal, all but two — and these children of some of the others, and not accustomed to take tea — were seized with nausea, vomiting, and the other symptoms of irritant poisoning, within five minutes after leaving the table. As these two had partaken of every other article, except the tea, suspicion was directed to that. When it was noted that the servant had not taken tea, as was her habit, and did not show any symptoms of sickness like the rest, suspicion rested upon her. While clearing off the table, she asked several questions as to whether if any poison had been put into the teapot, any of it would probably still remain there. During this discussion the interior of the pot was examined, and some white powder found upon the sides, so that it was set aside for further examination, she being ordered upon no account to touch it. Yet she did, when unobserved, remove it, rinsed and wiped out the interior of the pot, so that when again examined, nearly all the white powder had disappeared from where it was before seen.

The physician, when summoned, suspected the presence of arsenic poisoning, and gave proper treatment therefor. He made inquiries about the possible source of the arsenic; although none at first was thought of, the fact that a box of "Rough on Rats" had some weeks before been put away in the store-room, was at last remembered, and the box sought for, but found missing, although known to have been there but the day before. The next day it was found in another place. These and other facts led to the arrest of the maid upon suspicion of having added the arsenic to the tea.

Subsequent examination by a chemist disclosed the fact that the fluid decoction of the tea, as well as the tea-grounds and the interior of the teapot, especially of the spout, which could not be wiped out, all contained a large amount of arsenic, as did also the vomit of those who had partaken of the tea. Neither the

water from the well nor the unused tea contained any arsenic, but the dirty water found in a dipper upon the wash-stand in the maid's own room was found to contain some arsenic. The chemist testified that, from comparing the size of the whole crystals of arsenic composing the powder in the box of "Rough on Rats" with those found in the undissolved lump of white powder found in the spout of the pot, and the relative amounts of small, broken fragments found with each of them, that he was of the opinion that what was found in the teapot might have come from the box; that the difference between them, so far as there was any, was exactly what he would expect would result to powder from the box if it should be subjected to the action of boiling water such as the powder which was found in the pot must have been subjected to. These and some other facts presented to the court seemed to be sufficient cause for suspicion against the girl to cause her to be held for trial.

MEDICAL NOTES.

— The police authorities in Berlin have published an order requiring physicians to give written notice to the sanitary board within twenty-four hours after the diagnosis of the disease, in every case of puerperal fever, whether followed by death or not. The name of the midwife in attendance is also to be given.

BOSTON.

— The City Government in both branches has voted to accept the report of the joint committee on Public Health, appointed to give hearings on the existing regulations of the local Board of Health for the disinfection of foreign rags by a patent steam process. The report, which is a very sensible and judicious one, was accepted in the Common Council, notwithstanding the opposition of certain Democratic machine politicians, whose support can hardly be regarded as a *moral* endorsement of the action of the local Board of Health. We referred to this report, which should be read in full by all interested in the subject of rags as contagion carriers, in an editorial, September 2d.

NEW YORK.

— The King's County Insane Asylum, at Flatbush, is said to be in an extremely bad condition. In buildings which can accommodate fairly only eight hundred patients, there are now packed fifteen hundred; and on account of this disgraceful over-crowding, it is impossible for them to receive proper care, while they are in constant danger of the outbreak of an epidemic of infectious disease.

— Dr. Lewis H. White, for many years one of the leading physicians of Dutchess County, died of typhoid fever at his residence in Fishkill Village, September 24th, in the eightieth year of his age. His father was Dr. Ebenezer White, of Westchester County, whose two brothers, Barton and Harry, were also physicians, and he was graduated from the Medical Department of Yale College. He also received an honorary degree of M.D. from the University of the City of New York in 1835. He practised with great success for fifty-one years in Fishkill, where he was highly esteemed and beloved by the entire community, and where his son, Dr. Howell White, has for some time been associated with him. For eleven years he was President of the Dutchess County Medical Society.

Miscellany.

CONFERENCE IN WASHINGTON WITH REGARD TO THE FORMATION OF A CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

In accordance with a proposal emanating from the American Surgical Association, looking to the organization of a Congress of American Physicians and Surgeons to be composed from the principal specialist societies of the country, committees from the several societies appointed for the purpose met at Washington.

Among the gentlemen who appeared at the conference were the following:

From the American Surgical Association, Drs. C. H. Mastin, Mobile; J. Ewing Mears, Philadelphia. From the American Climatological Association, Drs. Frank Donaldson, Baltimore; W. W. Johnston, Washington. From the American Laryngological Association, Drs. F. I. Knight, Boston; E. L. Shurley, Detroit. From the Association of American Physicians and Pathologists, Dr. Wm. Pepper, Philadelphia. From the American Neurological Association, Drs. L. C. Gray, Brooklyn; J. Van Bibber, Baltimore. From the American Otological Association, Drs. C. R. Agnew, New York; W. H. Carmalt, New Haven, Conn. From the American Ophthalmological Association, Dr. O. F. Wadsworth, Boston. From the American Dermatological Association, Drs. H. G. Piffard, New York; G. H. Tilden, Boston. From the American Gynecological Association, Drs. S. C. Busey, Washington; J. R. Chadwick, Boston; Jos. Taber Johnson, Washington.

Dr. J. Ewing Mears was made Secretary, and Dr. S. C. Busey, of Washington, Chairman. A series of resolutions was adopted of which the purport was:

(1) That it was advisable to hold a conjoint meeting of the special societies in Washington during the month of September, 1889, and subsequently at intervals of three years.

(2) That the Societies be invited to elect each a representative to the Executive Committee of the conjoint assemblage, who are to have power to complete organizations by electing a President, Secretary and framing By-Laws, etc.

(3) That the conjoint meetings shall take place on two successive evenings, on the former there shall be an address, on the latter a topic for discussion.

(4) That in every respect the Societies shall retain their autonomy and carry out their own programmes.

(5) That any Society can withdraw at any time.

There was unanimity except that there was some discrepancy of opinion with regard to the frequency of the conjoint meetings. The majority favored *three* years, one or two favored intervals of five years.

The secretary was authorized to send copies of these resolutions to the several medical journals of the country.

Correspondence.

THE MEDICAL COLLEGE AND THE ROPER HOSPITAL AT CHARLESTON, S. C.

THE following letters, concerning the misfortunes in Charleston attendant upon the earthquake, and especially concerning the injuries suffered by the Medical College and the Roper Hospital, and which have been sent to the JOURNAL for publication, speak for themselves. It is only necessary to add that the letter from Dr. Kinloch was written in response to an earnest request from Dr. Bowditch, who is a member of the Boston Relief Committee, for a statement of the facts in the case.

ASHEVILLE, N. C., September 18, 1886.

MY DEAR DR. BOWDITCH, — The accounts given in the daily press regarding the destruction at Charleston, and the consequent suffering and prospective distress, have not in any way exaggerated the situation. The sympathy and generosity of the people of our broad country have touched the hearts of our people, and if, as it has been said, good often comes out of apparent evil, we all must recognize the great and lasting benefits coming now of a united brotherhood that knows no North, no East, no West, no South.

In calling your attention to the general condition of our afflicted city, I feel that I can add nothing to the picture as already drawn by so many of the witnesses upon the scene of trouble. In consequence of feeble health I have had to absent myself from home and to profit by a temporary sojourn in a mountain climate, but the daily communication had with my people enables me to speak as correctly as though I was upon the spot. As a medical man I am naturally much interested in the condition of the profession at home, and the destruction connected with our Medical College and our Hospital. I can give you some account of this, and leave you to consider our necessities. There are a few medical men who have suffered, and who can but poorly afford to lose anything. We are nearly all poor and dependent solely upon our daily work. The impoverishment of our city and State, incident to the unfortunate war between the States, has only in part been recovered from, and the consequence has been that even the medical men doing a good business have been but poorly remunerated. Medical fees cannot be large, and much charity practice has been done.

Our Medical College, as you know, is one of the oldest and most honored institutions of the country. Many of her Alumni are conspicuous and distinguished throughout the country. Since the war, with the multiplication of colleges at the South and West, we have had to depend almost solely upon the students of our own State. As one of the faculty of the college, I can say, without fear of contradiction, that we have been doing good work. We have upheld the good name of the school, have year by year been advancing the standard of education, and yet none of us have received remuneration worth mentioning. I have held on to my chair for many years simply because I felt a pride in keeping up the school which had been honored by a Dickson, a Moultrie, a Giddings, and a Gailliard. The college has no endowment, but had to be self-supporting. Now it has been practically destroyed by the earthquake, and will have to be rebuilt or suspended. We are told that it will be difficult to raise money by a loan and mortgage of the building, for such security would be poor. It will probably cost from four to five thousand dollars to enable us to go to work again.

Again the time-honored and noble institution, the Roper Hospital, upon which we depended for our clinical facilities, has been totally destroyed. This hospital was originally built through the charity of Mr. Thomas Roper. The Medical Society of our city were, under Mr. Roper's will, the trustees of the fund. The hospital was open to persons of all color and creed. With the bad fortunes of the war, this fund was so reduced that it was not sufficient to carry on the charity, and, as the next best thing to do, we, by permission of the courts, rented the building to the city, to be used as a hospital until our funds should reaccumulate, and allow us to open the building upon the former plan.

You will perceive, therefore, what an additional blow the Roper Fund has sustained. This charity is sadly in need of help. By the way, let me remind you that our old friend, Dr. T. Gailliard, together with myself, were the first medical officers appointed to this hospital. Dr. Gailliard had charge of the medical, and I of the surgical wards. We served long and pleasantly together. I am doubly interested in this charity, for it was through this that I acquired most of my surgical experience. Would that I had the means to richly endow it, and, in the evening of my life, to see the noble institution once more dispensing its rich blessings to all men who might stand in need of relief. I can say no more, my dear Doctor, after thus putting you in possession of the more important facts connected with our calamity, and which, no doubt, will interest you more particularly, as a medical man and a humanitarian. I say, in conclusion, God bless you for the interest you take in our affairs, and God bless the people of your noble city who have so generously responded to the wants of a suffering, but brave community. Inasmuch as you have done it unto the least of these, so sure will be your reward.

Sincerely yours, R. A. KINLOCH.

CHARLESTON, S. C., Sept. 15, 1886.

PROF. J. COLLINS WARREN.

My Dear Doctor,— Our Medical College, a self-supporting individual organization, dependent entirely upon its pupils, connected in no way with any city or State organization, is ruined, almost razed to the ground; our poor and helpless Faculty has determined to address prominent men in the profession throughout the States, to beg them to use their influence directly in aiding us to rebuild the old and venerable institution that has sent out such men as J. Laurence Smith, Marion Sims, Gaillard Thomas, and whose professional chairs have been filled by a Holbrook, a Dickson, a Shepard, an Agassiz, and others.

My dear Doctor, we are not ashamed to beg, and whatever you may do for us will be gratefully received and acknowledged by the Faculty and profession at large.

Yours most truly, M. MICHEL, M.D.

P. S. Make use of this letter among your colleagues, and ask them to help the old school.

INTRACAPSULAR FRACTURE.

EVERETT, MASS., September 20, 1886.

MR. EDITOR,— In your issue of August 26th, in page 191, I notice some remarks upon intracapsular fracture in the aged. Allow me to make a few suggestions in regard to this particular fracture.

Some years since, when examining a longitudinal section of the upper portion of a femur from the peculiar construction of the bone, I came to the conclusion, that, in a fracture of the neck from the usual accident, falling upon the trochanter with an impetus forward, the separation would commence at the upper surface, extending across until it reached the buttress of solid bone, when it would split down the entire length of this buttress and under the capsular ligament. This attachment of the fractured part to the capsular ligament by this fragment of the buttress accounts for the fact that there is but a slight shortening of the limb, rendering the result of the injury somewhat doubtful.

The surgeon in his manipulations to ascertain the character of the injury breaks up this connection; the limb being now released, is drawn up as far as the soft parts will permit.

If the limb is now drawn down the fractured surface of the femur comes in contact with that of the head and turns it down so that the femur only touches the upper edge of the fractured neck. The difficulty of a union in this situ-

ation amounts almost to an impossibility, whereas if extension had been made before the parts had been separated by the surgeon the fractured surfaces would have been brought in apposition, union would have commenced at the point under the ligament and progressed upward until a perfect recovery had taken place. In my work entitled "Conservative Surgery," this fracture is fully illustrated.

In the reduction of fractures and dislocations, I think, as a rule, too much force is used in the attempt to overcome the muscles. If the patient's mind is occupied by engaging him in conversation, and a very moderate amount of extension made, it will be found that the muscles will relax and the limb come down a short distance where it can be held by the surgeon and the moderate extension continued with the same result as before.

I will relate a case which fully corroborates this view. Some fifty years ago when assistant physician at Bellevue Hospital, New York, Dr. Wilson being resident physician, a patient in the Small-pox Hospital dislocated his shoulder. Dr. Wilson attempted its reduction, but did not succeed, and sent to the Middle House for assistance; Commodore McDonnough's son and I went to his aid. We all three made extension under Dr. Wilson's direction without affecting a reduction. Dr. Wilson then sent for the pulleys; while he was arranging these, I said to him that if he had no objection, I would try its reduction. He readily assented.

After removing my boots I placed one foot in the axilla, the great toe of the other foot against the process of the scapula, at the same time saying to the patient that he need not be alarmed as I was not designing to pull upon his arm, engaged him in conversation, and in two or three minutes the arm came down part way; in two or three minutes more it came down so that I felt the head of the humerus against the side of my foot, then with a push with both feet and bringing the arm into the side of the body the head was restored to its place.

I would call attention to the small amount of force used in this case to overcome the muscles. I will here remark that this case has long precedence of the one that Dr. Neil Macleod describes as a new method of reduction. I will relate a case in which reduction of a fracture was accomplished by a new process.

About forty-five years since I was called to see a young man who had fractured his femur at the upper third; there was a contraction of the lower portion of full two inches. He appeared to have a perfect horror of the suffering connected with setting a bone, and inquired very frequently if it would not "almost kill him when it was set." This suggested the idea of doing it without his knowledge; at the same time I recalled the fact that at the moment we drop upon the bed we relax all the muscles. Accordingly, when preparations were all made, I directed the assistants to hold him over the bed, taking charge of the fractured limb myself.

I put one hand under the place of fracture, the other clasping the knee, flexing the femur at the point of fracture for the purpose of opening the upper surface of the two ends. When all was ready I directed the assistants to lay him down. While he was being lowered I made extension from the knee and flexed still more at the fracture, bringing the ends of the bone in apposition, so that it was actually accomplished without his knowledge.

In this case but very slight traction was required, although the bones lapped over ten inches.

Deaths reported 1,920: under five years of age 869: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 504, consumption 269, lung diseases 110, diarrhœal diseases 287, diphtheria and croup 86, typhoid fever 42, whooping-cough 30, malarial fever 29, measles nine, scarlet fever eight, cerebro-spinal meningitis five, erysipelas four, typhus fever one. From whooping-cough, New York 10, Brooklyn six, Baltimore and Pittsburgh four each, Washington three, Cincinnati, Charleston, Lowell, Lynn, Springfield and Chelsea one each. From malarial fevers, New Orleans 12, New York eight, Brooklyn three, Baltimore two, Boston, Charleston, Lowell and Northampton, one each. From measles, New York seven, Brooklyn two. From scarlet fever, Pittsburgh four, Cincinnati two, Brooklyn and Boston one each. From cerebro-spinal meningitis, Fall River, two, New York, Worcester and Brockton one each. From erysipelas, New York four. From typhus fever, Brooklyn one.

In the 21 cities and greater towns of Massachusetts, with a population of 990,728 (population of the State 1,941,465), the total death-rate for the week was 21.47 against 23.61 and 20.51 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,093,817, for the week ending September 4th the death-rate was 20.8. Deaths reported 3,631: infants under one year of age 1,425; acute diseases of the respiratory organs (London) 128, diarrhœa 710, fever 58, scarlet fever 55, measles 46, whooping-cough 45, diphtheria 19.

The death-rates ranged from 14.2 in Bristol to 38.1 in Preston; Birmingham 23.5; Bradford 20.5; Brighton 20.6; Hull 16.6; Leeds 23.1; Liverpool 26.4; London 16.7; Manchester 28.8; Nottingham 18.2; Sheffield 28.2.

In Edinburgh 20.1; Glasgow 20.9; Dublin 26.2.

For the week ending September 4th, in the Swiss towns, there were 35 deaths from diarrhœal diseases, consumption 28, lung diseases five, whooping-cough and typhoid fever each three, diphtheria and croup two, erysipelas and puerperal fever each one.

The death-rates were: at Zurich 11.5; Geneva 14.1; Basle 14.1; Berne 13.9.

The meteorological record for week ending September 18, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps: —

NOTES ON SYPHILIS OF THE NERVOUS SYSTEM.[1]

BY JAMES J. PUTNAM, M.D.

THE DIFFERENTIAL DIAGNOSIS OF SYPHILIS AND TRUE EPILEPSY, IN PERSONS OVER THIRTY YEARS OF AGE.

The French syphilographer, Fournier, declares[2] that he has never seen a case of so-called idiopathic epilepsy beginning after thirty years of age, and that nine out of ten cases with this history are cases of syphilis.

This statement has often been quoted with approval, and is endorsed by H. C. Wood in his recent article.[3] It is supposed that in these cases the epileptic (properly epileptiform) attacks are only symptomatic of actual organic changes in the brain, but in another place Fournier offers the further opinion[4] that even in the early stages of syphilis functional derangements of the nervous system may show themselves, under the form of epilepsy, without organic lesion of the brain, and this view is likewise shared by other writers.

Other excellent and experienced observers, such as Strümpell[5] and Gowers,[6] consider it far from proved that syphilis is a cause, much less a frequent cause, of true epilepsy, although, in common with other organic brain diseases, it is a frequent cause of epileptiform convulsions.

According to the printed tables, including that of Gowers, it would seem that true epilepsy beginning after the age of thirty, although uncommon, is not so rare but that either Fournier's statement is in great exaggeration of the truth, or else cases are classed in them as epilepsy, which should come under the heading of symptomatic epileptiform convulsion; or else, finally, syphilis is a cause of true epilepsy oftener than is usually supposed.

Out of about 320 cases of epilepsy (or epileptiform convulsions of more or less chronic recurrence) which I find on my private and hospital records, there are forty-seven in which the first attack occurred when the patient was thirty years or more of age.

Of these, fifteen had to be counted out for want of sufficient record. Of the remaining thirty-two, sixteen had a pretty distinct syphilitic history, or offered present signs of syphilis; another patient was the wife of a syphilitic husband; two others had had gonorrhœa; and two admitted promiscuous sexual intercourse, though not syphilis.

One case was apparently of alcoholic origin; two were due to lead; and one to chronic gross disease of the brain. Excluding these last four cases, there were but six in which the history afforded no grounds for suspicion that syphilis might be present, and several of these were women, who are often infected by their husbands without their own knowledge.

Several of these six cases, on the other hand, seemed fairly to be called idiopathic epilepsy. One was that of a woman of excellent health, and over thirty years old, who was working in the Pemberton Mills at Lawrence at the time it fell in ruins, and was somewhat bruised and very severely frightened. An epileptic attack occurred that night, and they had recurred regularly during the twelve years preceding her examination. In two other cases the patients were under observation for a considerable length of time and no suspicion of syphilis was aroused. The other three cases were seen but once or twice, but gave a non-syphilitic history.

It is now worth while to see how far the other means of making the differential diagnosis would help us in deciding as to the doubtful cases in these three groups.

It is well known that inasmuch as syphilis usually causes epileptiform attacks by direct irritation of the cerebral substance, as any other organic intracranial disease might do, the fits ordinarily differ, in one or another respect, from those of the typical epilepsy.

Thus, consciousness is less apt to be fully lost, and the localized sensory or motor symptoms, such as are apt to usher in true epileptic attacks, may constitute the whole of the seizure.

Furthermore, the syphilitic patient is usually suffering from the constitutional effects of his disease, which may show itself in impaired nutrition, or in headache, vertigo, sleeplessness, and the mental deterioration and irritability so often met with in cerebral syphilis and especially significant if occurring at a period too soon after the appearance of the epileptic symptoms, to be considered as parallel to the mental deterioration of true epilepsy.

Again, there are often physical signs, such as enlarged post-cervical or epitrochlear glands, ulceration of mucous surfaces, alopecia, etc., which contribute to make the diagnosis presumptively certain. Finally, the crowning evidence is often furnished by the test of treatment. The question is, however, whether cases do not arise, and not so very infrequently, in which all of these signs fail, and yet where, on the evidence furnished by the age of the patient alone, we ought to use an anti-syphilitic treatment, and to persist in it in spite of the non-appearance of any great improvement, for the sake of avoiding possible future complications.

This last point is especially worthy of consideration. It is so common to hear the influence of anti-syphilitic treatment, often truly marvelous, spoken of as furnishing the touchstone of the diagnosis, that it is worth remembering that in the first place the eventual prognosis of nervous syphilis, under the best of treatment, is apt to be painted as too favorable; and in the second place, that, as Gowers has pointed out, while many of the symptoms such as headache, paralysis, etc., usually imply progressive advance of the disease, the mere presence of old or stationary disease, or of organic changes held in check by treatment, may furnish the irritation or instability necessary to keep up the epileptiform seizures.

Several of the cases which I believe to have been of syphilitic origin continued to have epileptiform attacks for a number of years, that is, as long as they were under observation, without showing any evidence of advancing disease.

A lack of susceptibility to large doses of iodide of potash is usually considered as an almost conclusive test of the presence of a syphilitic taint,[7] but I think the value of this sign is overrated.

I have recently been treating a patient with a sarcomatous tumor of the brain who took without difficulty 90 to 100 grains daily, and on the other hand I have seen a syphilitic patient who afterwards took enormous doses perfectly well, made uncomfortable at first by a small dose.

The truth in the matter is probably expressed in the following quotation from Brunton:[5]

"These symptoms (irritation of the mucous membranes, etc.), are most readily produced by small doses of two to five grains, and they may usually be arrested either by discontinuing the medicine or increasing the dose. When the dose is raised to ten grains the symptoms usually disappear, and I have only seen one case in which they persisted after the dose had been raised to thirty grains."

In other words, large doses, except perhaps at the very first, are better borne than small, and this observation I have heard confirmed by other physicians, though it has not found it way into the text books.

(To be continued.)

NOTES ON THE LAWTON MURDER.[1]

BY WILLIAM H. TAYLOR, M.D., OF NEW BEDFORD, MEDICAL EXAMINER.

On December 23d, 1885, at 9.30 o'clock, A.M., I was notified that the body of a man was lying in a wagon at Plainville, about three and a half miles from New Bedford, and that the surroundings indicated a violent death. As soon as possible I went to the place, arriving about ten minutes after ten, and found an express wagon, furnished with sideboards, drawn up to the wall at the north side of the road. This road, followed west, leads to Fall River, and in its easterly course passes through the towns of Acushnet, Rochester, Marion and Wareham. The wagon was a brown one with yellow trimmings and red wheels. The dashboard, footboard, thill, axletree, whiffletree and wheel on the right side were plentifully covered with recently dried blood. On the tailboard were two bloody smooches as though produced by bloody hands in closing the board. The board which ordinarily served to increase the height of the tailboard was missing, and was afterward picked up on a road in Rochester. The hind axle was badly sprung. Attached to the wagon was a dark chestnut horse with sweat dried on him, and evidently weary and hungry. The wagon contained a dozen or so of wood-colored boxes of the capacity of half a bushel each, and having the name "Lawton" on them in stencil. Seven of these boxes were closely stowed in the forward part of the wagon and contained eggs, one of the eggs being broken. The balance of the boxes were empty, and were piled helter skelter on the body of a man which was lying diagonally across the floor of the wagon, the head to the right near the tailboard, and the feet projecting five or six inches over the left sideboard, well forward. Before the removal of the boxes, it was noted that the wagon contained a small Japanese wolf-robe (lined with brown cloth and smooched with blood which had evidently undergone attempts at removal) and a horse-blanket, red and white checked, old and worn. A number of the boxes having been removed, the body came into view. It was that of a man thirty-five to forty years of age, rather below the medium height. The left side of the face was covered with dried blood into which dirt, and a few small, dry, brown leaves were matted, the leaves resembling those of the box-shrub. Numerous wounds were seen on the left side of the face, five being of special prominence.

At the back part of the head a wound was found from which blood was oozing on the bottom of the wagon. The body was not quite cold. Rigor mortis was observed in the legs only. About the neck was an old tarred hemp line as large as an ordinary clothes-line, which was tied in a "granny" knot on the right side, and had the appearance of being doubled. This rope had a long free end, and exercised no constriction on the neck. The clothing consisted of a brown mixed overcoat, blue undercoat, red cardigan jacket, dark vest, white shirt and paper collar, gray mixed trousers, underwear and stockings and black cloth boots, quilted. On the hands were brown leather gloves, well worn and bloody. All the clothing was blood-stained except the cardigan jacket, underclothes, stockings and boots. The boots were not muddy, nor was there any mud on the clothing except a spot on the back of the overcoat where it had laid on the floor of the wagon. (The day was warm for December, and the roads very muddy.) In the pockets were found a cigar, a few matches, a white handkerchief and a few worthless coins, but not a cent of current money. The inspection having been completed the body was arranged in the wagon and the whole affair was sent to the morgue in New Bedford under charge of a policeman. The body was identified on the spot, by a gentleman who well knew deceased and his habits, as that of Richard N. Lawton, of Westport, Mass., by occupation a collector of eggs in the towns of Wareham, Rochester and Dartmouth. He gave valuable information as to Lawton's probable whereabouts at the time of the murder, judging from the quantity of eggs which the wagon contained, and also stated that money in some quantity should have been found in the pockets. Inquiry along the road developed the fact that several persons had seen the wagon go by at daybreak, and almost all stated that the driver was a shortish man, with a black or dark mustache. This information, collected on the spot, probably assisted greatly in the speedy arrest of the criminal. A case of murder and robbery with subsequent transportation was readily made out.

An autopsy was held at 4.05 P.M., December 23d, at Wilson's morgue. After calling attention of witnesses to the position and appearance of the body as required by law, the examination proceeded. The body was that of a well-nourished and muscular man, five feet six inches tall, and would weigh about one hundred and thirty pounds. Very little rigor mortis, if any, was present. An evacuation of the bowels of ordinary appearance had occurred. Clothing was as before described. Subject had a brown mustache, and brown curly hair with a tendency to baldness at the forehead. A piece of tarred hemp line was removed from the neck. It was eighteen feet long, and had a standing bowline tied in the end giving the appearance of a double rope around the neck. The knot was situated just to the right of the median line of the chin, and, upon testing it, the rope did not slip. Three

[1] Read at a meeting of the Massachusetts Medico-Legal Society, June 8, 1886.

[5] Pharmacology, Therapeutics, etc. 1885. Lea Bros. p. 519.

fingers could be easily passed between the rope and the neck, and no furrow could be found on the skin indicating constriction. No marks of violence could be found externally, except upon the head. Post mortem ecchymoses were slight. Blood was dried in the ears, nose and mouth. The left side of the face was covered with dried blood containing dirt and a few small leaves. There were ecchymoses under both eyes. At the back part of the head on the right side near the median line, three and a half inches from the margin and just below the level of the top of the right ear, was a wound one inch by three quarters of an inch with ragged margins, from which blood oozed. On washing the face, no powder brand, burnt powder, or traces of wadding could be found. No wadding was found about the body or wagon. Five large wounds were situated in the space bounded by the left ear, angle of the mouth, lower jaw, malar bone, and zygomatic arch. The largest of these wounds was half an inch in long diameter, the smallest, a quarter of an inch; the remainder were between these sizes. The edges of these wounds were slightly blackened and were sharp cut. Beside these wounds there were forty or fifty small shot wounds scattered over the left side of the face. Only one shot wound was found to the right of the median line, and that was on the forehead. Several small shot wounds were seen under the chin on the left side. No wounds were found back of the left ear on the left side of the head. The small shot cut from these wounds were number seven or number eight bird-shot.

Section of the body showed that the heart was empty and contracted; the valves and walls were normal. The lungs were non-adherent, slightly emphysematous at apices, and generally anæmic. Ordinary post-mortem staining radiated outward from the bronchi to the surface. There were no sub-pleural ecchymoses. The bronchi of both lungs contained coagulated blood without froth. The larynx and trachea were normal. No ecchymoses were visible, and no evidences of pressure. The tongue was brown from dried blood. The hyoid bone was uninjured. There were no marks of pressure in the structures surrounding the larynx and trachea. Two buck-shot were found lying loosely in the pharynx; they had produced no injury at the site in which they were found. The liver, spleen, pancreas, kidneys, bladder and alimentary canal were normal. The stomach contained half a pint of partly digested food, in which could be distinguished beef, fowl, bread, potato, and other matters. The small intestine was the receptacle of matters which had undergone stomach digestion. The colon contained normal fæces.

The skull was extensively fractured. The charge of shot had torn through parts of the left temporal and sphenoid bones, breaking them into fragments, and carrying them into the brain. The ascending ramus of the jaw was fractured. The body of the sphenoid was fractured. Fractures radiated in all directions from the foramen magnum. A large, transverse fracture passed through both parietals at their back part, both temporals in the petrous portion, and the basilar process of the occipital. Around the wound of exit, the occipital bone was shattered to bits. Two buckshot were found at the wound of exit. One lay just inside the skull, and one, much flattened, was between the scalp and the skull. These buck-shot, and those found in the pharynx, were weighed, with the following result: The flattened shot weighed forty-seven grains, Troy; the others, thirty-eight and a half, forty-one, and forty-one and a half, respectively; total, one hundred and sixty-seven grains. The left internal and external carotid and basilar arteries were torn across, and the veins at the side of the neck, and the sinuses of the skull were freely opened. The large wounds of the face communicated directly with the interior of the skull through the sphenoid and temporal bones. Three fingers could be passed from the interior of the skull through this opening into the wounded region of the face. The right posterior lobe of the cerebrum was lacerated. The cerebellum was badly torn, the left hemisphere being nearly detached, and the right much lacerated. The medulla oblongata was cut through just below the olivary bodies. The spinal cord was normal. A blood-clot extended between the dura mater and the cord, from the foramen magnum to the second lumbar vertebra. The body was generally very anæmic.

Before discussing the points arising from the view and autopsy, it may be well to give an outline of the story of the murder, as brought out by the evidence accumulated by the police, and offered at the trial of Samuel F. Besse, for the killing of the man who furnishes us with the material for this paper.

Richard N. Lawton, a quiet, inoffensive man of unexceptionable habits and character, left his home in Westport, on Monday, December 21st, 1885, to take his usual route to Wareham and back, collecting eggs. He had with him probably between two and three hundred dollars. He arrived at Wareham that evening, and was seen by various persons. He passed the night at the house of Mrs. Long, who gave him his breakfast at about 8 o'clock A. M., Tuesday, and he then started to collect eggs. He called at a number of houses, as was his custom, and, about half-past ten, left the house of Mr. Handy to go to South Wareham by a wood-road which was uninhabited for some distance, and led past Blackmore's Pond. No one, except his murderer, ever saw him alive afterward, and the next that was known of him was the discovery of his body in Plainville, on Wednesday morning, fifteen or sixteen miles from Mr. Handy's house. Samuel F. Besse, the convicted murderer, was a desperate character, living with his father in a miserable hovel and a wretched neighborhood, in South Wareham. The locality bears the fitting name of "Hogtown." He had spent a long term in State Prison for burglary, and was a terror to the neighborhood. He knew Lawton's habits and the fact that he carried money with him, and it was known that he had contemplated robbery of this man for some time. On Tuesday morning, December 22d, he left his home about eight o'clock, taking his gun and buck and bird-shot of precisely the same character as those found in Lawton's head.

He waylaid Lawton as he came down the road from Handy's, and, secreting himself in the thick bushes at the side of the road, shot him. The location was determined by finding a cushion and whip belonging to Lawton near by, and upon assuming a position which it was reasonable to suppose was Besse's at the time of firing, the direction of the charge could be traced by the cut twigs of trees and bushes, and blood scattered about. Immediately after the shooting, the horse started, but, in sheering out, brought up on a tree-stump or log, which sprung the hind-axle. Besse caught him and turned him into the short scrub-oaks at the

side of the road, and, making evidence for his conviction by scrubbing the shrubs and small trees in his haste, and leaving the marks of uneven wheels on the ground, he found a good-sized tree some distance in from the road, in an unfrequented place, and tied the animal to it. This was shown by the tree being gnawed, the ground stamped and pawed, horse-droppings lying about, and a box, completing, with those found in the wagon, the original number which Lawton had on leaving home.

A most important witness for the prosecution was one Westgate, a companion of Besse's (as far as he thought prudent to be), who, at the time of the murder, was looking after some traps on the Weweantit River, an outlet of Blackmore's Pond. He was about a quarter of a mile away through the woods. He says he heard a team coming down the road, and voices. Then he heard two shots and some shouting. He looked after a few more traps, and then made his way to the road, where he met Besse. He inquired of Besse whose team it was that passed down the road, and what he fired at. Besse replied that he had seen no team, and that he had just shot a rabbit. After a little conversation on general topics, Westgate went home, leaving Besse in the road. Besse arrived home shortly after noon, and, having made some purchases, proceeded to devote his time to drinking.

He spent the first part of the night at a neighbor's, sleeping in a chair. About 3 o'clock A. M., Wednesday, he left the house, and, going to the place where the horse was secreted, he arranged his load, and, mounting the vehicle, urged the horse at as rapid a pace as possible through the various towns to Acushnet. As he entered Acushnet, still intoxicated, day was breaking. Several people saw him, marked his intoxication and his strange load, and one or two spoke to him. As he gained the country beyond Acushnet he met more people, and, concluding probably that the region was rather populous, he deserted the horse and wagon, and made his way through the woods and fields to New Bedford, where he was seen between eight and nine o'clock. A trifle of cunning seemed to remain in his intoxicated brain, for he went over to Fairhaven (across the river from New Bedford) to await the arrival of the morning train from the Wareham region, before showing himself publicly in New Bedford. While waiting for the street-car coming from the depot, he sat in an opening of a broken fence in a drunken sleep, and was seen by a number of passers-by. About noon he returned to New Bedford, and spent money freely for clothing, liquors, and other articles, and at four o'clock took the train to Wareham, his drunken state attracting the attention of the conductor.

On Thursday night, December 24th, he was arrested at a neighbor's house on suspicion, and in a short time evidence of the most convincing character fastened the crime upon him. He was tried at a special session of the Supreme Judicial Court at Plymouth, in May, 1886, and convicted of murder in the first degree. In this brief and condensed statement of fact, no special reference is made to the large amount of testimony necessary to establish the main facts as well as those of secondary importance; nor does the evidence concern us particularly as medical men except in so far as it has a bearing on the points having medico-legal interest.

At the preliminary hearing at Wareham, shortly after the murder, and at the hearing before the grand jury at Plymouth, the medical evidence was quite fully given. At the trial, however, very little work was given to the medical examiner. The defence admitted the cause and manner of the death without question, and the conversational powers of the witness received very little encouragement. But a very few questions involving statement of opinion were asked.

In preparation for the trial, quite a number of questions worth looking at presented themselves to my mind, and may be of interest to others.

I. How long had this body been dead when found at ten minutes past ten on the morning of December 23d? The body was not quite cold, and the only rigor mortis observed was a slight amount in the legs. According to our best authorities, the body cools in fifteen to twenty hours, the process being governed by the temperature of the surrounding medium. Under favorable circumstances it may be delayed to forty-eight hours or more. Warm weather, thick clothing or coverings, and a large quantity of subcutaneous fat favor slow cooling. Cooling is hastened by slight coverings, cold weather, leanness and death by hæmorrhage. Lawton's body was lightly covered, the clothing being open to the shirt. The temperature of the air was a little above freezing. He was not fat, and he had died with extensive hæmorrhage. And yet his body was not cold, though he must have been dead twenty-three hours when I saw him. Rigor mortis usually begins at the third or fourth hour, and is complete at the fifth or sixth. Exceptionally it may be complete as early as the second hour or as late as the thirteenth. No case has been reported in which its appearance has been delayed beyond twenty-four hours. It passes off in twenty-four to thirty-six hours in summer, thirty-six to forty-eight in winter. Exceptionally it lasts only two or three hours, and may possibly continue as long as three weeks. It appears first in the muscles of the face and neck, then in those of the trunk, and finally in the arms and legs. It passes off in the same order, the legs being the last to yield. In sudden death with no fatigue and with hæmorrhage, rigor mortis is apt to come on slowly and last a long time. This was the case with Lawton, and yet we find him lacking rigor mortis except in the lower extremities. It was reasonable to believe that rigor had come on and had been broken up by handling the body and jolting it about in the wagon. To be sure of this, I had the body carefully watched by the undertaker after it had passed from my hands. No rigor appeared. From the state of the body I did not feel warranted in approximating closely to the time of death, and gave as my opinion the statement that the body had been dead not more than thirty hours.

II. What was the cause of death? Three causes, either capable of producing death were evident. Shock, hæmorrhage, and section of the medulla oblongata. As the death was instantaneous, the last cause must have been the most important. How do we know that his death was instantaneous? This promised to be a point of some importance, but did not come up at the trial. As far as we know of instantaneous death, section of the medulla oblongata gives us the typical example. Again, the absence of froth in the bronchi, and the undisturbed coagula therein, showed plainly the method of death. Lawton's respiration ceased instantly. The heart continued to beat and pump the blood from the body as long as any came to its cavi-

ties, and finally stopped in systole. Had he breathed after being shot, we should certainly have found frothy, bloody liquid in the air-passages.

III. Could he have died from any other cause than gunshot wound of the head? What had the rope about the neck to do with his death? Fortunately, the answer is an easy one. Not one single symptom of death by asphyxia was present. The trachea and larynx, as before stated, showed no trace of injury, unusual redness or ecchymoses. The structures of the neck were normal. No furrow was found in the skin of the neck; no froth or frothy liquid in the air-passages; no congestion of the internal organs. It might be of importance to say that he was not hung first and shot afterward. Had this improbable state of things happened, we should still have had congestion of the abdominal organs, as the wounds of the head, at most, would have emptied only the vessels of the head and upper extremities. The generative organs showed no evidences of anything unusual, and the tongue was not swollen or indented. What the rope was used or intended for, must remain a sealed book, unless the convicted man sees fit to tell his story.

IV. From what direction and at what distance was the fatal shot fired? How can we connect the murderer with the missiles found in the body? The small shot wounds formed an ellipse, in the centre of which were the large wounds. These wounds were all on the left side of the face, some under the chin, but none back of the ear. The charge passed through the left temporal and sphenoid bones, along the base of the skull, and emerged a little to the right of the median line at the back of the head. It necessarily follows that the charge must have come from in front, somewhat to the left, and a little below the plane of the base of the skull. It is probable that Lawton was riding slowly along with the head slightly bent downward.

Authorities, surgical and medico-legal, are by no means agreed as to the appearances of wounds of entrance and exit. In most surgical works the dogma is maintained that the wound of entrance is always smaller than that of exit. As the other extreme we find Casper, who is equally dogmatic in the assertion that the wound of exit is always the smaller. Ogston, Taylor and Tidy recognize that many circumstances influence the appearance of these wounds, and that each case may present features peculiar to itself regarding the relative size of the two wounds, and the degree of inversion or eversion, laceration, and so on. Had any question arisen in this case, the fact that fragments of the temporal bone were found in the brain near the wound of exit would have settled the matter.

Westgate says he heard two shots. If two were fired, one only could have struck the murdered man. I conceive it to be next to impossible for a gunner to put two charges into a moving object in exactly the same relation. Again, had the first barrel missed, the victim would certainly have been disturbed and would have changed the position of his head. With regard to the distance at which the shot was fired, I have made some experiments with an old-fashioned muzzle-loading fowling-piece with very long barrels, which I knew to be capable of carrying shot very closely. In trying to obtain a powder-brand I used two and three-quarters drachms of rifle powder, at various distances. Briand and Chaudé, quoted in Medical Examiner Fish's admirable paper on pistol shot wounds,[2] state that powder-brand can be obtained at a distance equalling the length of the gun-barrel. Casper puts it at three or four feet, and Ogston, quoting Lachése, gives about the same figures. I was unable to get a powder-brand in the open air at a greater distance than two and a half feet; I certainly could not obtain one at the length of my gun-barrels, nearly three feet.

Partly burned powder would stick in bibulous paper in the open air at about eight feet; whether it would adhere to the human skin at that distance, I do not know. Wadding of good tough paper, well rammed, will be thrown twelve to fifteen feet against a slight breeze, and eighteen to twenty feet with the breeze. With my gun, loaded with two and three-quarters drachms of powder, one ounce number seven bird-shot, and twelve buck-shot, I could make a target closely resembling that on Lawton's head at twenty-five feet. Besse's gun was an old-fashioned double Manton with shorter barrels than mine and would probably not carry as closely. I put his distance from Lawton, at the time of firing the fatal shot, at eighteen to twenty feet.

In Besse's game-bag were found No. 7 bird-shot and 41 buck-shot, which, it was shown, he had purchased within a few days. The buck-shot were divided into groups of four, taken at random, and weighed by Professor Babcock, of Boston, who found that the fours averaged about a hundred and seventy grains. Some fours went as low as one hundred and sixty-three grains, and one, at least, over one hundred and eighty. As before stated, the four which I removed from the head and throat weighed one hundred and sixty-seven grains. An ounce of No. 7 bird-shot I found to contain from three hundred and fifty to four hundred, which would give a plenty to make the wounds on Lawton's face, as well as to cut the twigs of the trees and bushes in the line of fire. The method of loading is characteristic of an ignorant gunner, many men of this class having a belief that buck-shot will carry closer when backed by a charge of small shot.

Certain stains were found on the front of the legs of Besse's trousers. These had been subjected to attempts at removal, but not efficiently enough to ruin them for examination. The police sent these trousers, as well as a pair of boots worn on the night of transportation of the body, to Professor Babcock, of Boston; consequently, I did not see them until the day of the trial. Professor Babcock was fortunate enough to obtain the articles early enough to find blood-corpuscles in the stained places, and gave the very just and scientific statement that the blood was that of a mammal, that there was nothing inconsistent in the view that it was human blood, or that it was the blood of a rabbit. Certainly, where stains are sufficiently recent, the finding of corpuscles is the most conclusive test possible. I am inclined to think, however, that the time in which corpuscles can be distinguished in a blood-stain is shorter than is generally supposed, and I should place little reliance on observations made beyond a week or ten days. Some difference of opinion exists between authorities as to the value of the spectroscope in examination of blood-stains. Tidy is very enthusiastic in its favor, considers it infallible, and claims to have produced a characteristic spectrum from a stain

[2] Transactions Mass. Medico-Legal Society. Vol. I, p. 285.

known to be over one hundred years old. Others are more conservative, and still others assert that it is inapplicable in very many cases, requiring a good deal of technical skill, and, even in the best hands, proving unsatisfactory. I am not prepared to accept this last view. What little work I have had opportunity to do with blood has prepossessed me in favor of spectrum analysis, and, as it seems the only certain test, where it *is* clear and unmistakable, I think that hard work is well repaid which renders a man familiar enough with blood-spectra to be certain of their recognition.

Perhaps the best method to pursue with a blood-stain on cloth is that proposed by Ogston, which I will quote, with slight modification:

"The stained portion of the cloth is to be cut out and suspended by a fine thread in a test-tube containing distilled water. If the stain is from blood, the coloring matter will detach itself from the cloth in the form of reddish striæ, and collect at the bottom of the tube, while the water will there assume a red color, more or less pronounced.

"(1) A portion of the contents of the tube may now be used for the spectroscope.

"(2) Two or three drops of the fluid from the bottom of the tube may be cautiously withdrawn by a pipette, and examined under the microscope for blood-disks, epithelial-scales, or fragments of capillary-tubes.

"(3) Two or three more drops similarly withdrawn from the bottom of the tube may be placed on a slide, glacial acetic acid and a very minute crystal of common salt added, left to spontaneous evaporation, or gently heated, and when dried, examined by the microscope for crystals of hæmatin.

"(4) A little of the fluid may be dropped on bibulous paper and submitted to the guaiacum test.

"(5) A little more of the fluid, after the addition of ammonia, may be watched for any change other than a heightening of its color. If the red color comes from vegetable matters, it will be changed to blue, green, and so on.

"(6) The remainder of the fluid in the tube may be now heated, without or with nitric acid, for albumen, which, if present, will render it milky, or throw down a coagulum from it of a dirty gray color, leaving the water without a trace of red.

"(7) The turbidity or coagulum, if from albumen, will disappear or be re-dissolved on the addition of caustic potassa, and assume a brownish-red by reflected, and a green color by transmitted light.

"(8) When the stain has arisen from a layer of blood of perceptible thickness, the cloth, after the maceration, may exhibit a soft, white, grayish or rosy adherent matter, which, when removed and placed under the microscope, will prove to be the fibrin of the blood."

— The *Medical Record* speaks of a curious attempt at deception in a Russian peasant woman, who desired to pass off an infant as her own. In order to make it appear that she had just been delivered, she procured the lung of a sheep to answer as a placenta, and the seminal duct of a goat to represent the umbilical cord. The deception was discovered by Dr. Solovjeff, who related the case in the *Volkhski Vestnik*.

A FEW ADDITIONAL NOTES ON PSORIASIS.[1]

BY F. B. GREENOUGH, M.D., OF BOSTON.

The few notes that I have made on the cases of psoriasis that have come under my observation during the past dermatological year, hardly merit the title of a communication to the Association. I had hoped that some paper on this subject would be read, which would permit me to say the few words I wish to during its discussion. As, however, none such has been presented, I am forced to give you the results of my year's investigation on this subject, brief as they are, which briefness may perhaps be their greatest merit. My notes are supplementary to the paper I read last year,[2] containing the statistics as to sex, age of patients when seen, and, as far as seemingly reliable testimony could be obtained, the age when the disease manifested itself for the first time; also the evidence, either affirmative or negative, of a hereditary tendency.

In addition to these points, there is one in which I have been especially interested, which I referred to incidentally last year, but which was much more elaborately treated of by Dr. Sherwell in a later communication; namely, the fact that patients subject to psoriasis, as a rule, are remarkably healthy and strong. This, during the discussion, was doubted, and I thought I would test the matter as far as the number of cases that I should see would allow me to do.

I find on my case-books for the year from July 1, 1885, to June 30, 1886, twenty-five cases in dispensary practice, and seven in my private work. Of this number, that is, thirty-two, I have statistics of twenty-nine, the other three being cases that were seen when I was absent, and the records on these points were not noted by my colleagues. With the object of trying to reduce to numbers the condition of patients with psoriasis, as far as general health goes, I started to mark each case on a scale of five, that is to say, I assumed that five represented a patient in perfect health, and marked each of the twenty-nine cases on that scale. This is, of course, rough work, as I have not subjected the patients to a thorough examination, but when they seemed in blooming health, and reported themselves as being perfectly well, I have marked them five, and when they seemed below par, have marked them on that scale to the best of my ability. I must say, however, that I have been so anxious not to force the point that I hoped and expected to prove, that I really think I have been inclined rather to under, than over-mark. The points that my figures showed last year which seemed to me most interesting and important were not noticed, namely, the fact that while out of the whole number of cases seen, that is, three hundred and ninety-four, twenty-one were under ten years old, there were five cases who insisted that they were first affected by the disease after the age of fifty, and that in ninety-seven cases where the patients felt able to testify as to the fact of a hereditary tendency or not, thirty-one gave an affirmative answer.

The twenty-nine cases observed are tabulated below.

From this table, it appears that sixteen of the patients were of the male sex, and thirteen female. That the youngest case seen was nine years old. That in nineteen cases, what appeared to be reliable information as to the age at which the disease first mani-

[1] Read at the meeting of the American Dermatological Association, August 26, 1886.

[2] See Vol. CXIII, p. 24.

fested itself was obtained, according to which it was under ten in nine cases, the earliest definitely reported being at three years of age, and four being stated as having first shown symptoms of psoriasis during early childhood. That one case seen at the age of fifty-seven insisted that she never had had any similar trouble before. That these twenty-nine cases showed a percentage of psoriasis to total number of cases of skin diseases seen, that is, twelve hundred and twenty, of a little over two and one-third per cent. Twelve cases gave decided evidence as to the existence or not of psoriasis in their parents or other members of their family. Of these, four were affirmative and eight negative.

CASES OF PSORIASIS SEEN FROM JULY 1, 1885, TO JUNE 30, 1886.

No. of Case.	Health on a Scale of 5.	Sex.	Age.	Hereditary influence.	Age at the first manifestations.	Remarks.
1	5	Female.	50	....	....	
2	4	Male.	42	....	....

27	4	"	34	Yes.	Childhood.	
28	5	"	30	No.	....	
29	5	"	28	Yes.	Childhood.	

With regard to what I have been especially interested in during the past year, the condition of these patients as to general condition and health, while from my previous observations I felt sure that an attempt to make statistics bearing on this point would show that, as a rule, it was decidedly above the average, I did not expect to have my supposition confirmed as strikingly as it has been. I marked each case on a scale of five, and the average mark of the twenty-nine cases is a little over four and one-third! As I have previously said, this is loose work, but I have tried to be fair in my estimate, and have not given any case a five unless they looked and reported themselves as perfectly well. The careful examination of some of these cases might very possibly show that they were not as robust and hearty as they appeared, but in thirteen of the twenty-nine cases I felt justified in marking them five, twelve of them are scored as four, three as three, and one as two. The latter was a phthisical subject. One of the cases marked three reported having acquired syphilis ten years ago, and when seen, had well-marked specific cutaneous manifestations, concomitant with the efflorescences due to psoriasis, he himself appreciating the difference between the two lesions. It seems to me that this case where syphilis and psoriasis were seen on the same subject is a pretty strong proof against the theory of any connection between the two diseases. The fact, also, which I have been trying to prove, that the subjects of psoriasis are generally strong and healthy, would certainly tend to make the claim that psoriasis was in any way connected with a syphilitic taint untenable. The typical subject with psoriasis, as I believe, is perhaps rather too fleshy to be in perfect health. He is very well described by the German's expression of what he considers the best physical condition, "dick und fett."

I have not seen, and from what was said at our meeting last year, I have looked very carefully for it, any case where psoriasis showed itself on the palmar region. I do not mean that I have not seen an eruption on the palms that resembled psoriasis, because I have seen several, but they were all syphilitic, or, at least I thought so, and if I should see any such without symptoms of psoriasis elsewhere, I should much consider it *ipse facto* specific, and be very astonished if it did not yield to specific treatment.

Since the above was written, through the kindness of Dr. Tilden, I have seen a case which compels me to modify my statement. It was one of a boy, aged sixteen, strong, and with decidedly more than the average amount of muscular and adipose tissue, who showed lesions on both palms and on the upper, outside, and posterior aspect of the calf of one leg, a typical, almost circular patch of psoriasis about the size of a silver dollar, the vertical axis of which had been a little elongated. The left hand, which showed decidedly the most development of the disease, had been subjected to local treatment, so that beyond the fact that we had to do with a serpiginous-shaped efflorescence, covering pretty much the whole of the palm, of a non-ulcerative character, from which the horny layer was being separated, not much could be seen. The right palm, however, showed several lesions, such as I had never seen before, and I think that had I seen them, even in a case where there was no characteristic patch of psoriasis elsewhere, I should have hesitated before pronouncing them syphilitic. They were circular, from about one-eighth to three-eighths of an inch in diameter, scattered over the palm in such a way that their coalescing would produce a serpiginous lesion. The largest of them showed a raised margin of thickened epidermis with an almost cup-shaped depression in the centre, as though something had been picked out. There was no appearance of the characteristic silvery scales, nor was there any areola of congestion. The boy had not been working at any trade that would by the use of tools cause any irritation of his palms. He reported that he had been troubled with these symptoms for two years, and gave a pretty reliable account of one of his brothers having had a scaly eruption on his arms. The patient's elbows and knees were perfectly free from any lesions. His two outer lower incisors did show a faint tendency towards notching, but it was very slight, and otherwise he was a decidedly stocky, well-developed boy.

There was one case in which the result of treatment was very interesting to me. It was that of a very stout, strong young man, that I especially noticed, from the fact that one of my colleagues who saw it, was inclined to consider it as specific. The eruption was of short standing, generally developed, and had shown no signs of improvement during four or five weeks' treatment. One weeks' use of chrysorobin cleared his skin up entirely, and although afterwards there were some fresh manifestations they were easily kept under control.

I am perfectly aware of the fact that the mere sta-

tistical tabulation of cases of skin disease may be perfectly useless and uninteresting, nevertheless, from the observation of a large number of cases some facts of importance and interest may be deduced, and facts which cannot be got at in any other way. From the records which I have, of four hundred and twenty-three cases seen, the fact is shown that psoriasis appears, sometimes in early childhood, and sometimes not until the half century is past, and that the male sex is slightly more subject to it than the female. Also, it is proved that an hereditary influence exists in a certain number of cases. From the notes recorded on the twenty-nine cases seen during the past year it would certainly seem that the average physical development and general health was far above the average.

REPORT ON GENITO-URINARY SURGERY.

BY ABNER POST, M.D.

SUPRA-PUBIC CYSTOTOMY.

THE modern ideas in regard to the supra-pubic operation are comparatively well known to readers of the JOURNAL. The operation was treated in the editorial columns of July 16, 1885, and the effect of an inflated rubber bag in the rectum was described in a Report on Anatomy in Vol. CXIV, p. 225. The exact field of the high operation is not yet determined, but experience is doing much to show both the advantages of the operation, and the mishaps to which it is liable. No attempt will be made here to do more than give a few extracts and references to illustrate the differences in opinion as to the value of the operation, different operative procedures, and possible accidents.

In a recent volume,[1] Sir Henry Thompson announces his preference for the high operation, as improved by the method of Garson and Petersen. He believes that the distension of the rectum is valuable not only from the fact that the supra-pubic interval is increased, but from the circumstance that it places the bladder immobile in the surgeon's hands in the abdomen, and out of the pelvis.

At a meeting of the Royal Medical and Chirurgical Society of London, three cases on supra-pubic lithotomy were read, and a discussion[2] followed which brought out some important facts. Mr. Richard Barwell was surprised to find how little a safe degree of rectal distension raised the peritoneal fold. Dr. Garson said that Mr. Barwell's experiments had been made with the abdomen opened for four inches. His own had been made with the abdomen unopened as well. If the abdomen were opened first, but little, if any, raising of the prævesical fold of peritoneum took place.

Mr. Cadge said that in the cases so far reported there had been three of decided hæmorrhage. In one case, eighteen ounces of fluid were injected into the rectal bag, on the removal of which a drachm of blood followed; in a day or two suppression of urine set in, and the patient died. The necropsy showed advanced disease of the kidneys, and a wound of the rectum between it and the bladder, going through to the circular fibres of the muscular coat. Mr. Rivington said that it was dangerous to distend the rectum by anything more than twelve or fourteen ounces of fluid. In his own case, some bloody mucus was passed from the rectum for a day or two after the operation, though the distension had not been excessive.

Van Iterson,[3] of Holland, believes that the value of the operation depends upon the success of the suture of the bladder. If this does not prove feasible, he will return to the lateral operation. He has, so far, performed the supra-pubic operation eight times, with suture of the bladder. Only once has first intention failed. The mucous membrane was not included in the suture, and a soft rubber catheter was retained.

Janiszewski[4] reports two cases; the first case was a very unfavorable one for operation; the stone seemed to fill the whole bladder. The colpeurynter had little effect upon the position of the bladder, and the injection of the bladder was of little effect, because of the hypertrophy of its walls.

Dr. Arnold Schmitz,[5] of St. Petersburg, keeps his patients, who are children, on their face, the position recommended by Trendelenburg in 1877. His little patients are tied until the effects of the anæsthetic passes off, when they become quiet. They are not put upon two pillows with a free space between, as recommended by Trendelenburg, but upon an ordinary mattress. Next the wound comes a carbolic sponge wrapped in antiseptic gauze, over that a thick boracic-acid compress, then some impermeable stuff and the common gauze bandage. The sponge, which maintains a slight compression, is removed on the second day.

An unfortunate accident has occurred to the Parisian surgeon, Saint-Germain. After passing through the linea alba, the inflated rubber bag in the rectum was regarded as the bladder, and opened through the rectal wall, when the rush of air from the incision, and the collapse of the supposed bladder warned him of his error.[6]

Pousson[7] reports a case of rupture of the bladder from the injection of only 200 g. of a boracic acid solution, in the practice of Guyon. At least three similar cases have been previously reported.

At the fifteenth congress of the German Society of Surgery, König endeavored to establish the relative indications for perineal and supra-pubic lithotomy.[8]

Perineal cystotomy, Professor König concludes, is the less dangerous but the more difficult operation. It is suitable in ordinary cases of foreign body in the bladder and for the removal of stones of small and medium size. The high operation with regard to ease of performance is better suited for the removal of large stones; and the risks attending this operation, the principal of which is plegmon of the anterior abdominal wall, are much less than those likely to result from injury to the wound and bladder during perineal cystotomy performed under similar conditions.

THE RETRO-PERITONEAL AND THE COMBINED RETRO- AND INTRA-PERITONEAL INCISION, AS A MEANS FOR EXPOSING THE KIDNEY.

Any one who has attempted a series of operations on the kidney, in inflammatory changes of that organ, has realized how difficult it is with the customary incision in the loin, to make the kidney fairly approachable.

After researches on the cadaver and operations on

[1] The Supra-Pubic Operation of Opening the Bladder, by Sir Henry Thompson, F.R.C.S.

the living, Professor König, of Gottengen, has reached the following results:[9]

It is possible to make the kidney easily accessible by a retro-peritoneal incision, if the cut is made from the last rib downwards on the outer edge of the erector spinæ to a few centimetres above the ilium, and then curving forwards continuing the line towards the umbilicus and ending on the outer border of the rectus, or, under certain circumstances, continuing into this muscle. Sometimes it may be advisable not to make the incision in the loin vertical, but to carry it immediately somewhat obliquely, so that it passes over in a long curve into the cross cut toward the navel.

In the direction of the proposed cut, several muscles are incised or divided. The transverse cut divides the latissimus as well as the oblique and the transverse abdominal muscles and sometimes also the rectus, dividing all these muscles down to the peritoneum where they lie upon it. If it seems doubtful about recognizing the separate muscles after their retraction in order to unite them, one may run a thread through them as they are cut and designate the corresponding parts by knots as belonging together.

This cut, made in this manner, gives an astonishing accessibility, which can be decidedly increased if from the posterior vertical part of the incision, the peritoneum is separated with the hand and pushed forward, which is easily accomplished to a considerable extent.

This incision König would designate as retro-peritoneal lumbo-abdominal (Leudenbauchschnitt) incision, (with displacement of the peritoneum forwards.)

If the proposed cut does not give sufficient room, or if for adequate reasons it appears desirable for diagnostic or operative purposes to make the tumor approachable from the abdominal cavity the peritoneal covering may be cut in the transverse incision. This part of the incision must evidently, as it opens the abdominal cavity, be carefully conducted in case infectious material is to be evacuated from the kidney or its pelvis. Usually it would be possible to close at least the peritoneal incision, before removing or opening a suppurating kidney.

This incision Professor König would distinguish as retro-intra-peritoneal lumbo-abdominal incision.

A NEW PROCEDURE FOR THE REMOVAL OF SMALL CALCULI FROM THE BLADDER IN MALE CHILDREN.

Mr. Thomas Annandale reports the following operation upon a boy of four and one-half years, the subject of a small stone. Under chloroform the urethra was dilated, the bladder injected with antiseptic fluid, a small lithotrite passed and the stone seized. The handle of the instrument was then depressed causing its vesical extremity together with the stone to be felt through the abdominal wall immediately above the pubes. A small incision was then made which allowed the lithotrite to be pushed through the wound, the stone was extracted and a No. 9 india-rubber catheter was seized and drawn into the bladder as the lithotrite was withdrawn. A tube was inserted through the abdominal wound. After forty-eight hours both tube and catheter were removed, and the patient was well on the tenth day.

Mr. Annandale believes this to be a much less serious proceeding than the ordinary supra-pubic operation, as the bladder is scarcely disturbed and the wound made in it is very limited.[10]

COMBINED INTERNAL AND EXTERNAL URETHROTOMY.[11]

Mr. Reginald Harrison has combined the two operations in twelve cases with good results. In considering the subject he first enumerates the objections to internal urethrotomy, and the advantages of Symes's operations. Internal urethrotomy is extremely liable to be followed by a form of fever which is exceptional, unexplainable, and occasionally fatal. In the second place it does not furnish better permanent results than other methods of treatment. The conditions which generally attend the operation of internal urethrotomy are unfavorable to the best kinds of repair. The section which is requisite for the division of the contraction necessarily paralyses the urethra for rather more than the extent of the wound inflicted, and the process of repair has to be carried on with the wound soaked in the urine that is left behind to stagnate and to undergo change after each act of micturition. This is a very different thing from the flow of urine over the open wound of a lithotomy or a perineal section. In internal urethrotomy there is retention within a confined space, in external urethrotomy there is merely contact of urine with open surfaces. The latter operation unfortunately cannot include the whole of many strictures by reason of their position and relation to the perineum; for instance, those within the limits of the scrotum or in the penile urethra. In combining the two operations, Mr. Harrison's object was to secure that the healing process following the division of the stricture should proceed without being subjected to those influences, immediate and remote, which he ascribed to the presence of stagnant urine in the wound. He desired that the "cicatricial splice" should be formed under circumstances most favorable to repair.

Mr. Harrison's plan consists in doing first, thoroughly and completely, the internal urethrotomy. A grooved staff is then introduced into the bladder, and the membranous urethra opened for the passage of a drainage-tube into the bladder.

Mr. Harrison makes the perineal incision or perineal puncture, as he prefers to call it, as follows: The patient being placed in the lithotomy-position and a grooved staff introduced, he punctures the membranous urethra with a long straight finger-knife one inch in front of the anus, the back of the knife being towards the rectum; the incision is slightly enlarged forwards, so as to permit the introduction of the index-finger; if the staff is found exposed at the bottom of the wound, as it generally is, all well and good. If not, a somewhat blunt knife is introduced on the finger and the remaining fibres divided. (The plan of the incision is first to make it fit the finger, and subsequently the drainage-tube; if this is done accurately, there is practically no bleeding.) Wheelhouse's small, probe-pointed gorget is slid along the staff which is then withdrawn and the drainage-tube passed along the concavity of the gorget into its position. The drainage-tubes are somewhat less in size than the index-finger. They are secured by an eye at each side through which a tape can be passed. The end should be just within the bladder and no more. When the internal urethrotomy has been freer than usual, a drainage-tube is introduced from the meatus and brought out at the perineal wound by the side of the bladder drainage-tube. In other cases it is sufficient

[11] British Medical Journal, July 18, 1885.

to wash out the anterior portion of the canal with some antiseptic fluid. The cases operated upon included the worst and most unpromising, but so far there have been no rigors nor urinary fever.

SECTION OF THE HYPERTROPHIED PROSTATE.

Mr. Reginald Harrison proposes to treat certain cases of prostatic obstruction by division of the gland, access to the field of operation being gained by means of the bontonniere as in the manner of treating sessile growths proposed by Thompson. The most formidable form of obstruction which the prostate affords, is that most amenable to division when the gland grows not in lobulated masses but by an upheaving of its floor. Although the obstruction both to the escape of urine or the introduction of an instrument into the bladder may be very complete, the amount of tissue requiring division is not necessarily large. The operation consists in opening the membranous urethra from the perineum on a guide and introducing the finger within the prostatic urethra. The obstructing portion of the gland is then divided in the median line partly by incision with a straight probe-pointed knife and partly by divulsion with the finger or large-sized bougie until the access to the bladder is felt to be free. In doing this operation it is not desirable to make an opening larger than will admit the index-finger from the perineum into the bladder; such an opening is completely filled up by the drainage-tube that is subsequently used, and consequently but little risk of hæmorrhage need be entertained. Considerable importance is attached to the prolonged use of the drainage-apparatus as the object is to render the section of the prostate not a temporary one but permanent. The tubes are retained from six to twelve weeks.

It will be observed that section of the bar is preceded in all instances by a careful digital exploration of the prostatic urethra, with a view of directly determining the nature of the obstruction and the direction of the incision to remove it. Mr. Harrison records the following case. D. E., came under his care in 1883, with an atonied bladder and retention of urine from enlarged prostate. There had been great difficulty in passing the catheter and much blood had been lost. The patient was childish and would not retain a catheter. After three weeks' trial of various forms of treatment the operation described was done and a bar of considerable thickness divided. Hæmorrhage and cystitis disappeared. The patient was able to go about in ten days, his urine being discharged at will by turning a tap connected with the drainage-apparatus. The tube was retained for eight weeks when a considerable quantity of urine began to escape by the urethra. The tube was withdrawn and the wound rapidly closed. This patient has never had any further impediment to the natural escape of urine along the urethra. He could retain his urine for four hours, and there was no residual urine, nor was there any difficulty in passing a large-sized instrument into the bladder. Six months after the operation the patient had a paralytic seizure from which he has not recovered, but resort to catheterism has never been necessary. The introduction into the prostate of no inconsiderable quantity of cicatricial tissue has probably something to do with the result.

The author advocates the free incision of the enlarged prostate during the lateral operation for stone and the retention of a tube for six, eight, or ten weeks so as to bring about a permanently improved condition of the outlet.

THE TREATMENT OF CHRONIC URETHRAL DISCHARGE BY EXTERNAL URETHROTOMY.

Mr. Reginald Harrison [12] relates a case of urethral discharge of four years' duration, which had resisted all the usual methods of treatment, including internal urethrotomy, which was cured by this means. An india-rubber tube was passed through the perineal opening into the bladder and retained there for twenty-five days.

Therapeutical Memorandum.

ACUTE RHEUMATIC CARDITIS TREATED WITH SALICYLATE OF SODIUM.[1]

BY SAMUEL L. ABBOT, M.D.,
Visiting Physician, Massachusetts General Hospital.

I WAS called, on the evening of February 8th, to Madame ——, a Frenchwoman, who had been suffering for a week from an attack of acute rheumatism. She had had no medical advice, as the symptoms were not very urgent, and she "hated doctors." Domestic remedies had been employed, such as sinapisms, enveloping the affected joints with cotton, etc. For the first four nights sleep had been much interrupted by pain, but the patient had slept pretty well on the fifth and sixth nights. She had had an attack of acute rheumatism three years before, which lasted seven weeks. At the time of my visit, she was in a comfortable condition so far as pain was concerned. The feet and ankles, knees, shoulders, and right hand had been inflamed, but were now free from pain; the feet, however, were puffy with œdema. The left arm and hand were enveloped in cotton and not painful, except on motion or firm pressure; the hand was œdematous.

The patient was very drowsy, finding it difficult to keep awake, and had dozed most of the day; it was this condition which had excited alarm in her friends, and led them to call in medical advice. It was not difficult to arouse the patient, so that she answered questions intelligently, but languidly, as if overwhelmed with stupor. She had taken no medicine, and said she had no pain. She was taking sufficient nourishing food, and had committed the indiscretion of eating meat for dinner the day before. Her breathing was very quick, apparently without any sense of dyspnœa, the respirations being forty-six in a minute. Pulse 112, regular; of moderate force; temperature 105.4° in the axilla.

On examining the chest, nothing abnormal was detected in the lungs in front, and I did not deem it expedient to raise her to examine the back. The cardiac dulness was not increased. The sounds of the heart were clear and distinct, of moderate force, and a loud, systolic souffle was heard throughout the cardiac region, loudest over the aortic valves, and heard faintly beneath the left clavicle. Considerable tenderness was found on pressure in the intercostal spaces over the heart, which the patient had not been conscious of before. The tongue was nearly clean, and moist; salicylate of sodium was prescribed, to be taken in ten-grain doses every two hours.

[1] Read at the Boston Society for Medical Improvement, May 24, 1886.

[12] Lancet, September 5, 1885.

The patient slept well during the following night, and was free from pain and tenderness over the heart the next morning; the systolic souffle, however, continued. She was very bright and smiling, entirely relieved of the stupor of the previous evening, and said she had very little recollection of what had occurred during my visit at that time. She had taken five doses of salicylate of sodium during the night, and had perspired very freely; the œdema continued. The temperature had fallen to 98.6° — nearly seven degrees. Pulse 100, respirations 20. The urine was high-colored, strongly acid, contained an excess of urates, and was of specific gravity of 1016; there was no trace of albumen. Treatment continued.

February 10th. The patient had slept well, and had no pain. There was some deafness, with tinnitus. The left hand was still somewhat puffy, but could be used freely without discomfort. There was still slight œdema of the feet. A faint systolic souffle could be detected over the base of the ventricles, but could scarcely be heard over the aortic valves. The patient stated that she had not been conscious of any cardiac disability following the first attack of acute rheumatism three years before. Temperature 97.6°, pulse 84, respirations 18. The salicylate had been given during the night, and was ordered to be continued every two hours, in alternate doses of ten and five grains, the dose to be increased *pro re natâ*.

February 11th. The patient is free from pain, having slept well. Tongue nearly clean. At the second left intercostal space, over an area extending to the left, about an inch and a half square, the systolic souffle can be distinctly heard, with a slight reduplication of the sound of the pulmonary valves, the souffle being scarcely audible over the aortic valves, and very faint at the apex. No friction-sound has been heard from the first. Urine still turbid with urates. Temperature 98°, pulse 80, respirations 16.

The patient was allowed to sit up and eat a little chicken with her broth, having taken milk and broth freely from the first. Tr. Ferri Chlorid. mx, Glycerin. mxv, aquæ ad fzi was prescribed, to be taken after each meal. The salicylate of sodium was omitted, to be resumed *pro re natâ*.

February 12th. The patient felt well, and was sitting up in bed at time of visit, having been up out of bed half of the previous day. Bowels regular without medicine. Has had no pain or dyspnœa. The souffle can hardly be heard over the aortic valves, and is very faint over the region where it was so distinct the day before. Decided accentuation of the pulmonary valves; no souffle heard at apex. Temperature not taken; pulse 84. The patient has not required the salicylate of sodium. The iron was ordered to be continued, and full diet was allowed.

February 17th. Since the 13th the patient has been up and about the house the whole of each day, feeling quite well, except that she is not very strong. Nothing abnormal can be detected about the heart. A pill of quinine, iron, and nux vomica was prescribed, to be taken before each meal, instead of the tincture of the chloride of iron.

The leading features of the case may be summarized as follows:

The patient, when first seen, had been ill six days with acute rheumatism, for which she had had no medical treatment. On the seventh day, symptoms of stupor and her general condition excited alarm among her friends, who called in the writer, who found the patient with a temperature of 105.4°, rapid respiration and heart action, with tenderness over the cardiac region, and a cerebral condition looking like impending coma, suggesting very forcibly the closing scene of fatal pericarditis. On examination of the heart, a loud, general systolic souffle was heard, but no friction-sound.

Treatment with salicylate of sodium, without any local applications, was followed by a very rapid disappearance of the cardiac and cerebral symptoms, and speedy recovery, the patient being able to sit up half of the third day after the treatment was commenced, and all day after the fourth. Scarcely a trace of the morbid physical signs was detected on the fifth day, and nothing abnormal on the ninth.

At the time of the first visit, with the history of a previous attack of acute rheumatism, it was impossible to form an opinion whether the souffle detected was due to that attack or to the present one. The rapid disappearance of this symptom settled this point, and raised an interesting question as to its origin. Taken in connection with the cardiac tenderness, the œdema of the affected joints, the accompanying rapid respiration, and the high temperature, and the fact that the morbid sound lingered last over the base of the ventricles, I cannot resist the conviction that the case was one of rheumatic myocarditis, and the abnormal sound was muscular, rather than valvular; for it seems hardly possible that an inflammatory valvular change, sufficient to produce so loud a murmur, could have disappeared so quickly. My impression is strengthened by reading the interesting paper of Dr. West on "Parenchymatous Myocarditis," published in the *London Lancet* of January 20th and 27th of the present year, in which the first case reported was characterized by a similar souffle, but in which, after death, the autopsy showed nothing abnormal about the valves, but marked evidence of myocarditis; and Bramwell, in a paper published in the *American Journal of Medical Science* for April, 1886, speaks of "cases of mitral and tricuspid regurgitation due to simple dilatation, and to structural changes in the cardiac muscle" ("relative and muscular incompetence," as he terms them) — "conditions which are very common during life, and which may be unattended with any naked-eye lesion of the valvular apparatus after death."

If my view of the case now reported be correct, it strengthens my impression of the value of the salicylic remedies in the cardiac complications of acute rheumatism claimed for them in my paper on "Rheumatic Pericarditis," read before this Society at the meeting of January 11th, and published in the *Boston Medical and Surgical Journal* of January 21st of the current year. I am glad to find my position sustained by Professor Latham, of Cambridge, England, who, in his third Croonian Lecture on "Some Points in the Pathology of Rheumatism," delivered at the Royal College of Physicians of London, in April, 1886, and published in the *Lancet* of May 1st, says, in speaking of the power of salicylic acid over acute rheumatism: "In no case of rheumatism that has come under my care during the last six years, either in hospital or private practice, has there been, where the heart was previously sound, any cardiac complication, such as endocarditis or pericarditis, developed." And again: "Cardiac complications constitute the chief danger of acute rheumatism, and the danger, if the disease is taken in hand soon

enough, may, with our new remedy, be averted." He insists, however, upon pure salicylic acid alone being employed, and says that he "has given it in rheumatism complicated with pericarditis, and as yet has seen no bad result from it." So far as my experience goes, I can say the same of salicylate of soda, with the addition that recovery from this cardiac complication in the few cases in which I have had an opportunity of trying it, has been the result, and this without resort to the favorite, and, I must think, the doubtful alkaloid treatment.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

MAY 24, 1886, the President, DR. F. W. DRAPER, in the Chair.

DR. G. H. MONKS showed, by invitation, colored models from original dissertations of the

DISTRIBUTION OF THE CUTANEOUS NERVES.

DR. J. J. PUTNAM read a paper on

SYPHILIS OF THE NERVOUS SYSTEM.[1]

DR. R. T. EDES was glad that these cases had been analyzed. The curability of syphilitic lesions of the nervous system has at times been somewhat exaggerated, although they do sometimes improve rapidly.

DR. C. F. FOLSOM said that the relation of syphilis to these diseases is something of which we as yet know little. How much is directly due to syphilis, and how much to the body being long debilitated by syphilis? in how many of them is syphilis latent? how often do we have these diseases when syphilis is properly treated from the beginning? how often when it is not so treated? He thinks that in a large proportion of cases general paralysis is a late lesion of syphilis. In seventeen cases he has found fifteen histories of syphilis. In Ireland it is a much more rare disease than in England or Scotland, and so is syphilis. It is possible, however, that it depends merely on the debility caused by syphilis. The effect of iodide of potassium in its treatment has been over-rated. When paralysis is distinctly local, we do get benefit from the iodide, but we have to use large doses. He had given a drachm without effect, and had seen marked benefit from half an ounce to six drachms.

DR. PUTNAM said that he had tried to learn what has been the treatment in the early stages. He asked if, notwithstanding the modern theory as to the need of prolonged treatment of syphilis, it is not a fact that most patients are allowed to pass from under observation with the cessation of the first symptoms. He thought that it was so.

DR. J. C. WHITE said that ten years ago, prolonged treatment of early syphilis was not insisted upon. To-day it is almost entirely confined to specialists in syphilis and dermatology. Nine cases out of ten of advanced syphilis were treated at first only two or three months — long enough to remove the symptoms. He was sorry to say, however, that he had himself treated cases persistently for twelve to twenty-four months, and that among these there had been some late and severe forms of nervous syphilis. It is impossible to state how far nervous symptoms may be warded off by proper treatment. The paper, in his opinion, labored under the difficulty that many cases were considered that we do not know to be syphilis, except in so far as we can judge by the cerebral symptoms.

DR. PUTNAM stated that he had tried to tabulate cases in which there were cutaneous and other distinctly syphilitic symptoms, and that all that we can do with others is to repeat observations constantly, watching the effect of syphilitic treatment.

DR. S. L. ABBOT read a paper on

ACUTE PNEUMATIC CARDITIS TREATED WITH SALICYLATE OF SODIUM.[2]

DR. F. C. SHATTUCK said that Dr. Abbot's very interesting case brought out several questions. The diagnosis of myocarditis is one of the most difficult to make during life; and, while it cannot be denied that the souffle and the tenderness in the region of the heart noted in this case were very likely due to this process; another explanation seems very possible. As to the causation of some heart-murmurs, our knowledge is very precise; as to others, it is very vague. In high fever of whatever nature, a murmur is frequently heard over the heart, entirely apart from any inflammatory process in any portion of the cardiac structure, as far as we know. Such murmurs are called dynamic by some, and are attributed to relaxation of the heart-muscle, and consequent imperfect closure of the mitral valve. In the case under discussion, the fever was very high — proportionally higher than the pulse-rate — but not so high as the respiratory-rate, and the murmur became much less marked as the pyrexia fell under the influence of the salicylate. A purely dynamic murmur often behaves in the same way. As regards the tenderness over the region of the heart, this symptom might be attributed to a rheumatic affection of the fibrous structure about the ribs and their cartilages, especially in a case of rheumatic polyarthritis.

Moreover it seems to be very doubtful whether the salicyl compounds really exert any direct protective influence on the heart and pericardium. That they control the fever and the articular symptoms of acute rheumatism in a very remarkable degree there can be no question. Dr. Howard, of Montreal, who contributes the article on rheumatism to "Pepper's System of Medicine," goes carefully into the question of the development of cardiac inflammation during the salicyl treatment, and brings together a series of large number of cases reported by different observers which tend strongly to show that the prophylactic influence of these remedies over the heart is certainly very small. Dr. Howard, himself, in common with many other skilful physicians, believe that the best treatment of acute rheumatism consists in a combination of the salicylic and the alkaline treatment. The fever and the articular symptoms are relieved by the first, the danger of cardiac complications is greatly diminished by the second. The question involved demands and deserves further study; and can only be settled by a careful analysis of a very large number of cases, occurring in different years and localities, and under different but trustworthy observers. But the drift of opinion at present seems to be against the power of salicylic acid directly to influence rheumatic cardiac inflammation, an additional argument that perhaps

[1] See page 317 of this Journal.

[2] See page 326 of this number of the Journal.

myocarditis was not present in the case reported by Dr. Abbot.

Dr. Abbot in reply to Dr. Shattuck admitted the general difficulty of a confident diagnosis of carditis, but he thought the case reported presented all the features of a genuine metastases to the heart. The rheumatic inflammation had attacked joint after joint, with the usual local symptoms. These had subsided and the cerebral and respiratory symptoms came on as a sequence. The patient was seen during the first day of these symptoms and was found in a very alarming condition. The local pain was developed by pressure in the intercostal spaces over the heart, but not over the ribs or cartilages, nor in the intercostal spaces elsewhere. The pulse is confessedly variable in rheumatic carditis, and is not necessarily very quick. Dr. Shattuck was in error in his impression that the murmur became at once much less marked as the pyrexia fell, under the influence of the salicylate. On the morning after it was first administered the temperature had fallen to 98.6°, with entire relief to the tenderness and stupor, but the souffle was just as strong as before the administration of the remedy, and diminished gradually during the following days, the temperature remaining at a low point; as if the inflammatory change in the heart structure were subsiding by degrees just as occurs in a rheumatic joint, after the acute pain has disappeared.

The cause of the murmur in these cases is confessedly difficult to determine; but Dr. Abbot thought that the theory of inflammation suggests a reasonable explanation, in the embarrassment it would be likely to cause to the free contraction of the heart muscle, by which the normal action of the columnæ carneæ would be seriously interfered with.

THE AMERICAN GYNÆCOLOGICAL SOCIETY.[1]

A CASE OF ABDOMINAL SECTION FOR CHRONIC SUPPURATIVE PERITONITIS.

By Dr. John C. Reeve, M.D., of Dayton, Ohio.

A., aged nineteen, living as if married, was healthy until November last. She had never been pregnant. She was attended by a physician who found abdominal inflammation. On January 18th, she was seen in consultation by the speaker, at which time she presented the evidences of chronic peritonitis, but no history of a gonorrhœal origin could be obtained. One month later she began to pass pus by the rectum. After other measures of relief had failed, laparotomy was offered in April, but declined. The patient was not seen again until June 20th, when she desired the operation. She had suffered with hectic, the menstruation had ceased since January, and examination of the urine showed no albumen. There was great tenderness and hardness all over the abdomen, pus being still passed with the stools. By vaginal examination, no definite hardness could be detected. By the rectum there was ill-defined resonance high up on the left side. No opening into the rectum could be detected, although frequent examinations for this purpose were made. The patient was greatly emaciated, the weight having fallen from one hundred and twenty-five pounds to seventy pounds.

The operation was performed June 23d; there was great difficulty in the administration of the ether. On opening the peritoneum all the parts were matted together. The abdomen was washed out by allowing water to run into it from a pipe, and then syringing out what remained. Finally a cavity was reached in the left lumbar region. It was impossible to attach the walls of this cavity to the abdominal wound, and as the condition of the patient was by this time alarming, a drainage-tube was introduced and the abdominal incision closed with sutures. In the course of several hours the patient gradually rallied from the operation. The temperature did not go above 100°. The cavity was washed out with a solution of iodine in tincture in water. The upper two-thirds of the abdominal wound failed to unite. On the fourteenth day a large quantity of fæcal matter came through the wound. This has continued to recur. In July, evidences of Bright's disease were detected; since then there has been some improvement in the general health. I think that if the patient had consented to the operation when first proposed, the result might have been different. One of the principal objects of the paper has been to ascertain if, as has been stated, fæcal fistula is an invariable consequence of laparotomy for abdominal inflammation in cases where pus has already escaped by the rectum.

[1] Continued from page 309.

DISCUSSION.

Dr. J. Scott, of San Francisco. I would mention the following case. A patient was admitted to the hospital with prolapse, inflammation of the ovaries and cellulitis. After three months' treatment without improvement, removal of the ovaries was recommended but declined, by the patient. The patient was kept under treatment for six months longer, when enlargement of the right ovary began. Later, pus discharged by the rectum, and subsequently, the abscess opened into the bladder. The patient then consented to operation. The abdomen was opened, an opening made into the vagina and a drainage-tube introduced. The improvement was not marked, and in the course of two months the patient was as bad as ever. The removal of both ovaries and tubes was then performed. Four or five days after the operation fæces appeared in the wound. During the five months succeeding the operation the fæcal fistula has closed, the patient has gained ten pounds, and is able to walk about.

Dr. William Goodell, of Philadelphia. The only case which I have had at all similar to the one reported was one of pelvic abscess, opening into the rectum and bladder. I performed laparotomy with the intention of opening the abscess and stitching its walls to the abdominal wound. The abscess had been so constantly drained, that it was not larger than a pear. By compressing the abscess sac, I was able to make it prominent in the vagina and forced into it a closed pair of scissors, which were then opened and the opening gradually enlarged and a drainage-tube inserted. This case gradually recovered, both the rectal and vesical openings closing in the course of time.

Dr. C. C. Lee, of New York. I think that the rule will come to be established that in chronic suppurative peritonitis, laparotomy is not only justified but the procedure to be adopted.

Dr. R. S. Sutton, of Pittsburg. In a case of pelvic abscess as large as a cocoanut, I performed laparotomy and then stitched the peritoneum at the edge of the incision to the peritoneum covering the abscess,

which was then opened and a drainage-tube introduced. The patient recovered.

Dr. Joseph T. Johnson, of Washington. I would suggest that in such cases as the one described by the author where time is a matter of importance, much can be gained by adopting the procedure employed by Drs. Bantock and Tait. In washing out the abdominal cavity they pour the water into the cavity with a pitcher, using gallons at a time. In this way the cleansing is rapidly accomplished.

Adjourned.

WEDNESDAY.— SECOND DAY.— MORNING SESSION.

ERGOT AFTER LABOR.

By Dr. John Goodman, of Louisville, Ky.

In the absence of the author, the paper was read by the secretary. The administration of a full dose of ergot immediately after the completion of labor has become a general practice. It is claimed that it promotes involution, prevents after-pains and tends to prevent post-partum hæmorrhage. Some years ago, the author administered a full dose of ergot after a perfectly normal labor. In fifteen minutes, severe pain appeared and increased. The tenderness in the uterus continued for a week. There was no milk, and the patient, previously prolific, never again conceived. The trouble was attributed to inflammation of the muscular coat of the uterus produced by the action of the ergot.

In a second case, treated in May, 1886, ergot was given after a forceps delivery. On the seventh day the patient had a chill, followed by a temperature of 104°. The next day a clot was washed out of the uterus, and the temperature fell to 99°. Well-marked septicæmia developed, and the patient died one week later. In this case, the retention of the clot was attributed to the spasmodic contraction of the uterus, preventing its escape. The author has seen other cases in which injurious effects were produced by the administration of ergot.

He claimed that ergot did not assist involution, which was a natural process, and required a certain length of time for its completion. That we have in ergot a remedy capable of arresting after-pains cannot be doubted, but it does so by exciting a mode of muscular action at variance with all physiological laws. After-pains are conservative, and it is better to wait until they become of abnormal severity before resorting to treatment. Ergot is capable of preventing hæmorrhage, but its use is attended with such dangers that it should not be employed, except under exceptional circumstances. It should be an inviolable rule not to give ergot at the close of the third stage of labor, unless hæmorrhage is imminent. It should then be used by hypodermic injection.

DISCUSSION.

The President, Dr. Thaddeus A. Reamy, of Cincinnati. I have in process of preparation a paper in which is entered my protest against routine practice of the administration of ergot after the third stage of labor. This conclusion is based upon my experience, and upon a study of the action which is claimed for the drug. The contractions produced by ergot are unlike those of nature. The contraction of ergot is persistent, while the normal contraction is intermittent. If the contraction is persistent, the circulation of the uterine wall cannot reach a healthy state, and thus it not only retains what is in the uterine cavity, but it interferes with the process of involution, and lays the foundation for sepsis and inflammation. I think that in the course of the next five or ten years, the practice of obstetricians in this matter will be revolutionized.

Dr. William Goodell, of Philadelphia. The author of the paper states that it is only since last May that he has given up the use of ergot. I think that he has not had sufficient time to form such positive opinions. In the first case, I think that there must have been a fibroid tumor; the second case was a clear instance of septicæmia. I do not think that after-pains are conservative. As a rule, we do not see them in primipara. These pains are in great measure the result of weaknesses induced by civilization. I do not believe that every woman who has given birth to a child needs ergot, but we do not know the cases which do require it. In twenty-five hundred cases of labor, I have always given ergot after the completion of labor, and I have never seen any harm from its use. I do not believe that one dose of ergot has much effect in favoring involution. Involution is the result of fatty degeneration, and the greater the contraction, the greater the interference with circulation, and the more rapidly should this change take place. I have used ergot for two purposes: one to prevent hæmorrhage, and the other to prevent the absorption of septic matter. Since the introduction of antiseptics, which, I think, should be used in every case of labor, whether public or private, the use of ergot to prevent septic infection is not so important. I think that it does not do the harm which has been mentioned.

Dr. George J. Englemann, of St. Louis. I hold, in the main, the views which the President has expressed. I use ergot much less than I did a few years ago. I believe that we have equally effective measures in the hot antiseptic douche and in the Faradic current. After the contents of the uterus have been expelled, ergot will, in certain cases, always be a useful and effective remedy. I would not venture to say that after labor ergot is out of place, but I think that I may say that before the contents of the uterus are expelled, it should not be used at all.

Dr. Theophilus Parvin, of Philadelphia. The effect of ergot varies with the dose. A small dose acts simply to increase the normal uterine contractions. I must object to the assertion that ergot should never be given before the completion of labor. Statistics show that those who are most successful in the treatment of placenta prævia are the men who use ergot. Again, in a multipara, with the os dilated, where a sudden rupture of the membrane has taken place with a cessation of labor, fifteen or twenty grains of ergot causes a rapid completion of the labor. After a protracted labor, there is a weariness of the uterus, and a failure to enter upon the normal retraction, which is a preventive of hæmorrhage, and tends to promote involution. As long as in the third stage of labor we assist Nature in the expulsion of the placenta, why should we not assist Nature in securing normal retraction of the uterus after the completion of the third stage? In some experiments which I made at the Philadelphia Hospital, to determine the rapidity of involution of the uterus in women who had received ergot, and in those who had not, it was found that in those who received ergot after delivery, uterine involution seemed to take place more rapidly.

Dr. Skene, of Brooklyn. I have never seen such effects from ergot as have been described in this paper. I do not think that in the cases reported the ergot had anything to do with the production of the effects. All rational men use ergot as any other remedy, when it is necessary, or may possibly become necessary. If there is any doubt whether or not it is needed, it is better to give the patient the benefit of the doubt.

Dr. P. C. Williams, of Baltimore. I believe that ergot has its place in obstetrical medicine. I have never yet regretted its use in any case, but I have regretted not using it. The great danger under the use of anæsthetics is hæmorrhage. To avoid this, the use of ergot seems to be the proper thing. I admit that ergot is abused, but the abuse of ergot is no argument against its proper use.

Dr. Thaddeus A. Reamy, of Cincinnati. The profession is not taught that ergot should be given in diseased conditions, but that it shall be given in all cases after labor, as a routine practice, and it is only against this use of it that I raise my voice.

The next business was the reading of the

PRESIDENT'S ADDRESS,

by Thaddeus A. Reamy, M.D., of Cincinnati.

The speaker first referred to the prosperity of the Society during the past ten years, and spoke of the great advance of abdominal surgery and ovariotomy during the same time. The speaker thought that the less satisfactory results obtained in America, as compared with other countries, might be due to climatic and constitutional conditions, and to the fact that the operation was performed by too many operators. The operation of removal of the ovaries for beginning cystic troubles and for other conditions is performed in many cases which could be relieved by other and less serious measures. The practice of Schroeder in leaving the undiseased ovary was recommended. The success of ovariotomy has led to the performance of laparotomy on other conditions, as suppurative peritonitis, with satisfactory results.

The use of electricity as a therapeutic agent is attracting much attention. It is the safest and most effective remedy in extra-uterine pregnancy, and it is coming into use in many other uterine conditions.

The treatment of extensive fibroid disease was next taken up. Medical treatment is in the main unsatisfactory, although, in some cases, good result has followed the use of ergot and electricity, especially the latter, which is perhaps the most effective therapeutic agent in these cases. The operation of hysterectomy should not, as a rule, be performed in these cases. Spaying has met with more favor and success than any other surgical procedure. There are a few cases where, on account of the large size of the tumor, or its fibro-cystic character, hysterectomy probably affords the best hope.

Pelvic deformities were next considered. In the lesser degrees, premature labor, with the use of appropriate forceps applied with proper skill, were recommended. With reference to operative procedures, the mortality in the United States has been very great. An important reason for this is the failure to recognize the importance of early interference. It has also been shown that, other things being equal, the danger is increased by doing the operation after the death of the child.

The total extirpation of the uterus for cancer has been steadily growing in favor. So far as the speaker had examined, the clinical proof of the evidence as to its utility had not been convincing. While patients had recovered from the operation, it is not yet proven that the operation is justifiable, except where the disease is confined to the body of the uterus or the cervix, and the vagina is free. While the view that epithelioma of the cervix is due to traumatism is not generally accepted, he believed that traumatism of the cervix was conducive to the development of epithelioma. If for no other reason, Emmet's operation is warranted on the sole ground of a preventive.

The speaker, in referring to the uterine curette, stated that he had recently had alarming symptoms following its use, and in one case where the instrument was used immediately after dilatation with sponge-tents, death resulted. Peritonitis had not been developed in a single case where the dilatation had not immediately preceded the operation. Rapid dilatation is alleged to be comparatively free from the dangers attendant upon the use of tents, but he had recently had a high degree of peritonitis following dilatation by this method, where the curette was not used.

The following rare case was then described: A married woman, aged thirty-two, the mother of two children, had suffered with severe menorrhagia during the past year. There was an old laceration of the perineum, but no laceration of the cervix. The uterus measured three and one-fourth inches, and was not tender. No pelvic tenderness could be detected. Treatment directed to the general condition was ordered, and under it the anæmia improved and menorrhagia decreased. Some months later the blunt curette was used, with the woman in the lithotomy position. No dilatation was required. A large amount of the fungus tissue was removed from the posterior wall, and the curette was then passed over the anterior wall. During the manipulation, no roughness being employed, the instrument passed through the uterine wall. It was at once withdrawn, and a sound being introduced, it readily passed its whole length, and its extremity could be felt externally above the umbilicus. Forty drops of laudanum was administered by the rectum, and an ice-bag placed over the abdomen. The ice-bag was kept on continuously for five days. The accident caused no symptoms whatever. The perineum was subsequently restored, and the woman's health is much improved. The menorrhagia has disappeared.

In concluding, the President referred to the proposition looking to the organization of a Congress of American Physicians and Surgeons, and hoped that the action of the Society would be favorable to such an alliance.

THE INFLUENCE OF MENTAL IMPRESSIONS ON THE FŒTUS,

by Dr. Fordyce Barker, M.D., of New York.

The belief that maternal impressions may affect the nutrition and development of the fœtus in utero has existed from the earliest periods of which there are any records. Medical writers with hardly an exception, down to the beginning of the eighteenth century, express the belief with more or less distinctness that fœtal marks and deformities are due to the emotions, desires or shocks of the pregnant mother. Reference was then made to numerous papers written within the past twenty years in which this theory was strongly controverted. Those who disbelieve in

this doctrine base their scepticism on what they regard as physiological reasoning and chiefly on the assertion that there is no direct nerve connection between the maternal and fœtal system. Deformities they urge are due to arrest of development; but no one has brought forward sound physiological reasons why this arrest of development may not have been caused by mental impressions affecting the fœtal nutrition by their influence on the maternal blood. Extremely rare as is the occurrence of cases which prove the result of this influence, he considered the fact is so well proved by sufficient authentic evidence as to make it as certain as any other fact which cannot be explained by science. The term "mental impressions" should include those which have a physical as well as a psychical origin.

Five cases coming under the author's observation were described.

The first case was that of a young lady, who at the age of eighteen had for the first time been taken to the theatre and had seen Sothern, the actor, in the part of Lord Dundreary. From this time she spent her whole time in writing to Lord Dundreary, and she thought and talked of nothing else. This continued several months and under treatment and change of scene, gradually wore away. She subsequently married, and four years after her attack of insanity, her first child, a boy, was born. As the child became able to talk he exhibited peculiarities, resembling those of Lord Dundreary. He walked with a little skip, had a slight stammer in his speech, and his left brow was drawn down with the lids partially closed.

The second case was that of a lady, a typical brunette, who was first married to a gentleman, a typical blonde. She was never pregnant by him. Subsequent to his death she married a gentleman as marked a brunette as herself. Her first child was a decided blonde. Both her own and her husband's relatives are all brunettes. The lady has since had three children all brunettes.

The third case was that of a lady who during the first month of pregnancy had been much worried over her oldest daughter who had had her ears bored for rings. The ears became inflamed and caused much trouble. When the child was born both ears presented the appearance of having been pierced for rings, and through at least one of the lobes a thread could be passed.

Case fourth was that of a lady who at a very early period of pregnancy was much impressed by seeing three ladies, all of whom had hare-lips. When her child was born it had a double hare-lip.

Case fifth, Mrs. X., married but a few weeks was at the theatre with her husband. Something vexing him he placed the point of his elbow on her hand and held it so firmly that she could not draw it away. Not wishing to make a scene, she bore it until she fainted. The fingers were much swollen and painful for several days. She never lived with her husband afterwards. Thirty-five weeks and three days after the theatre incident she gave birth to a son. On the left hand the first and second phalanges of all the fingers and thumb were absent, looking as if they had been amputated. During her pregnancy she had never thought that her child would be born with any deficiency.

Other reported cases were then referred to.

DISCUSSION.

Dr. William Goodell, of Philadelphia. I have been very sceptical on this subject, but I have seen one case which seems to bear out the theory. A physician was called upon to assist at the operation of circumcision. His wife, who was in the early months of pregnancy was much interested in the operation and insisted upon having all the detail. The operation and its cruelty occupied much of her thoughts. When her child was born, a boy, it was found that the gland was exposed, the prepuce well retracted with granulating edges, showing the appearance very similar to that of a recent circumcision.

I have recently seen an almost identical condition in a child, which could not be accounted for by any impression on the mind of the mother.

Dr. Samuel C. Busey, of Washington. While I have no positive convictions to present, I believe that there is some relation between mental impressions and fœtal deformities. Any prevalent and concurrent belief must be based upon an element of truth. This belief has prevailed since the time of Jacob. At the present time it is a fixed belief in the female mind. In the physical world there is no effect without a cause, and in the world of life the rule is the same. If we can demonstrate in any single instance one connection between the deformity and the mental impression, we must concede that such a thing can again occur. If there are any number of cases where we can show a precise correspondence between the impression and the deformity, the relation must be accepted as presumptively proven. Dr. Barker has cited some instances, and Dr. Goodell has given another case. In another case the mother while pregnant saw a man with an opening in his trachea, from which a tracheotomy tube had been removed. The child when born exhibited a depression in the same position. Another case is reported where the mother received two distinct impressions, and the child was born with two distinct deformities corresponding to the separate impressions received. In another case, the father had removed, in the presence of his mother, a metacarpal bone of one of the fingers. When the child was born it exhibited a corresponding deformity. A consideration of these cases can bring us to but one conclusion. The earlier in pregnancy the impression occurs the more frequently does the deformity follow, and the greater is the correspondence between cause and effect.

The discussion was then postponed until afternoon.

AFTERNOON SESSION.

Dr. John Billings, of Washington. There are many cases on record which cannot be explained by any knowledge which we now have. As to the influence of previous pregnancies on the characteristics of subsequent pregnancies, we have no scientific information. If we could obtain the statistics showing the characters of children born of different fathers we should have some scientific data on which to form an opinion.

Dr. Fordyce Barker, of New York. In all the cases I have reported there is no evidence that the period since conception had been more than six weeks. I have rejected all cases in which conception occurred three or four months before the mental impression was produced.

(To be continued.)

Medical and Surgical Journal.

THURSDAY, OCTOBER 7, 1886.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., *Boston. Price, 15 cents a number; $5.00 a year, including postage, to subscribers in the United States and Canadas. Foreign subscribers are charged the postage in addition.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.

CUPPLES, UPHAM & COMPANY,
283 WASHINGTON STREET, BOSTON, MASS.

THE FORMATION OF NEW TISSUE FROM ASEPTIC BLOOD-CLOTS.

THAT blood-coagula will organize and form new tissue after a destructive operative procedure, is the new phase in wound treatment presented by Schede at the last Congress of German Surgeons. Accustomed as we have been to regard blood-clots as foreign bodies to be carefully removed from a wound, this statement is somewhat startling; but after reading Schede's carefully-observed results, and remembering that hæmatoma of large size not infrequently disappear, and that it has long been known that blood-clots in an aseptic wound are innocuous, we feel somewhat prepared to accept Schede's remarkable statement.

His reported results are almost marvellous; the blood fills the wound cavity completely, clots, and is gradually replaced by permanent tissue formation, without further wound secretion. By this method, resections of large joints have healed by primary union, large portions of the articular ends of bone, with the whole of the cartilage surface, have been removed without impairment of the articular function.

Two hundred and forty-one operations are recorded by Schede, and nearly all of these have healed under one dressing by primary union; among the operations performed are the removal of large sequestra from bone, the erasion of fungous granulations from the sheaths of tendons, the division of all the soft parts, including the astragalo-scaphoid ligament (Phelps's operation), and many excisions of joints and removals of tumors.

Especially adapted to this method of treatment are wounds of bones, joints, and cavities having stiff walls; it is not advisable in wounds of the soft parts. To secure these results, one must completely remove all diseased (tubercular) tissues and all foreign bodies (sequestra or fragments of bone) from the wound, which must be aseptic, accurately filled with blood from parenchymatous bleeding, and provision should be made for the escape of an excess of blood by overflow drainage openings, situated at the highest point of the wound surface; finally, one must, as far as possible, favor the evaporation and drying of the excess of blood by the dressing. Of course, to obtain such results, one must follow carefully the plan laid down by Schede for operative procedure. This we will give somewhat in detail; for example, a limb is exsanguinated by an Esmarch's bandage, the knee-joint is resected, visible arterial lumina are secured, the tourniquet is loosened and spurting points are ligated, and the cavity of the wound is allowed to fill with blood. Then all tissues from the periosteum to the skin are carefully approximated. No drainage-tube is used. The wound is covered with silk protective, which must lie perfectly smooth, and this is covered with a sublimate gauze dressing, interposed with layers of cotton batting, which is secured in place by rollers of antiseptic gauze; a splint is applied to the back of the leg, extending from a foot-piece to the waist, and this is finally secured in position by plaster-of-Paris bandages. Schede has resected forty large joints, with thirty-seven typical recoveries; and he has never been obliged to change this dressing from leaking of blood or wound secretion. Bone cavities, however, are treated in a little different manner, in that the skin and soft parts are caught together, with appropriate intervals for the escape of an excess of blood. Over the blood-filled cavity is accurately adjusted a piece of silk protective one or two centimetres larger than the wound; this serves a double purpose, in that it secures the accurate filling of the wound with blood and prevents evaporation and drying of the blood-clot, within the cavity of the wound. The silk protective is covered with the dressing as applied to the knee-joint. If any doubt exists regarding the asepticism of the wound Schede advises packing it with iodoform or sublimate gauze until it can be made so, then when good granulation tissue appears he scrapes out the wound and allows it to fill with blood which he covers in with silk protective as above and considers that he materially hastens the healing of the wound.

Schede considers the failures which have followed his treatment to be due: First, to the incomplete filling of the wound with blood; this can be avoided by loosening the Esmarch before applying the dressing. Second, to the recurrence of tuberculosis in wounds from incomplete removal of diseased tissues, for instance, in severe cases of general tuberculosis the coagula will not organize. Third, the failure to remove all foreign bodies from the wound, sequestra, etc., which may cause fistula in the cicatrix. Fourth, there is occasionally a fungous degeneration of the cicatrix as in wounds otherwise treated.

We are certainly indebted to Schede for boldly acting on his conviction that blood-clots will organize and form new tissue, and his eminently satisfactory results should attract the attention of all practical surgeons.

A MEDICAL VIEW OF THE TEMPERANCE QUESTION.

SUCH was the title of the brief, but comprehensive and suggestive paper read by Dr. Francis Minot, of Boston, at the American Unitarian Conference at

Saratoga, September 22d. The care and accuracy which characterized the statements of this paper caused it to appear in striking contrast with much that has been paraded before the public on such occasions as fact and science.

Against the popular view that alcohol is, under all circumstances, and especially to the healthy human system, a poison, Dr. Minot contended that a moderate quantity of pure ethyl spirit, well diluted, may be taken daily by healthy individuals without harm. This is the view defended by the late Dr. Austin, and by a great majority of physicians, and it is in accordance with the experience of many natures.

This admission, however, did not appear in the mind of the essayist to make total abstinence, as a general principle, any the less a matter of expediency, and often of positive duty. The word *moderation* is a vague and indefinite term, which, in some individuals, may connote almost an infinitesimal quantity of alcohol ingested, the excess-margin being speedily reached.

The pathological effects of alcohol, when taken in excess, pertain especially to the digestive tube, the liver, the heart, and bloodvessels, and above all, the brain and nervous system. But while the drunkard's "petuitous dyspepsia" is common enough, Dr. Minot failed to find evidence that ulcer and cancer of the stomach (two quite frequent gastric affections) were ever caused by alcohol. In his opinion, too, cirrhosis of the liver is a comparatively rare affection, although, when occurring, it is generally of alcoholic origin. Bright's disease of the kidneys is less frequently due to abuse of ardent spirits than has been supposed

Cardiac and vascular degenerations (atheromatous diseases) find their most frequent source in intemperance. But it is on the delicate nerve-cell and fibre that alcohol exerts its most pernicious influence. Not only are meningeal inflammations and insanity due to the irritation of alcohol, but there are minor cerebral alterations, which find expression in change of character, in inaptitude and disrelish for the higher exercises of mind, in action deriving its motive from the lower propensities.

Among the causes of alcoholism, Dr. Minot gave great emphasis to the predisposing, the principal of which is heredity. Multitudes (and the essayist thought the majority) of the victims of this deplorable vice derive from their parents or ancestors that instability of nervous organization which renders the appetite, when once formed, a controlling one; in such persons, drunkenness readily becomes a disease, comparable to other nervous diseases of a more or less periodical nature.

The therapeutical aspect of the question the lecturer did not touch upon, but hinted at its immense importance. As for treatment, the truth was recognized that vastly more can be done by prophylaxis than in any other way, and this especially in reference to the multitudes who are organically predisposed to alcoholism. Here a timely warning may save a life from ruin.

It would be well if Dr. Minot's address could be issued in the form of a tract for distribution in the public schools, and as an antidote to much of the trash that is now taught there in the name of science.

MEDICAL NOTES.

— The new medical practice law in Iowa is, as might be expected, meeting vigorous opposition from the advocates of "liberty." In a recent examination of a candidate for a license, among many other interesting replies were the following on midwifery, according to the report of a Western contemporary: "He was asked if he had ever attended any case of labor; he replied that he never did a day's work. His wife said that he had always been lazy, but that during the summer he had pitched three loads of hay. He was then asked if he had had any cases of obstetrics in the past year, and replied that he had not. He was then asked if he knew of any case of obstetrics occurring in his neighborhood during the past fifteen years, and replied, after deep thought, that he did not."

— M. Paul Leroy-Beaulieu, in an interesting paper in the *Economiste Français*, quoted in the *British Medical Journal*, gives the following figures, showing the quantity of tobacco consumed in the different countries of Europe, and the rate per 1,000 inhabitants is, according to him, as follows: Spain, 110 lb.; Italy, 128 lb.; Great Britain, 138 lb.; Russia, 182 lb.; Hungary, 207 lb.; France, 210 lb.; Denmark, 224 lb.; Norway, 229 lb.; Austria, 273 lb.; Germany, 336 lb.; Holland, 448 lb.; and Belgium, 560 lb. In other words, while in Spain little more than 1 lb. per head is consumed, nearly double that quantity is consumed in France, three times as much in Germany, four times as much in Holland, and five times as much in Belgium.

— The desideratum of a process for the synthetical manufacture of quinine, has, according to the *Lancet*, apparently been secured. The synthetical manufacture of quinine was first suggested to Mr. Cresswell Hewett in 1869 by the late Dr. Mattheson, of St. Bartholomew's Hospital, whilst giving his assistance in a course of experiments in connection with apomorphia. Subsequently, Professor Parkes of Netley, aided with his advice, and to these gentlemen, rather than to himself, Mr. Cresswell Hewett modestly explains that the process is due. The importance of this discovery is rendered greater by the fact that, while hitherto we have been depending for our quinine on the cultivation of the cinchona tree, from whose bark only about two per cent. of good quinine can be extracted, 98 per cent. being valueless, the drug can now be manufactured without limit by a very simple process from an article which can always be got in abundance in any part of the world. Mr. Hewett, it is said, intends to put himself in communication with the British government, who annually spend in India

alone about £60,000 in the cultivation of the cinchona tree. His process, it is claimed, will produce the drug for 3*d.* per ounce.

— We learn by an account in a recent issue of the *New York World* that another rare and wonderful operation has been performed with brilliant results. This time it was a very painful cancer, situated in the dangerous locality of the breast. The skilful surgeon at the hospital was willing, however, to take all risks to save the life of the patient. The incisions were carefully and judiciously made "in the direction of the fibres of the great pectoral muscle," the slightest deviation of the blade inviting death. The knife was carried "around the diseased mass in such a manner as to include *every part of it*, the lower incision being made first." The pectoral muscle was "thoroughly exposed by the removal of its fibrous envelope." "Strict antiseptic precautions" were observed, and, *mirabile dictu*, the wound "healed by first intention," without any increase in the temperature. All this shows what advances are constantly being made in our noble art by bold and skilful surgeons. We hope, however, that success will not make some of our operators too bold. Who will be the first one to tackle "a wen?" — *N. Y. Med. Record.*

— A case of attempted suicide from acute mania, recently treated in one of the New York hospitals, has served to call renewed attention to the hardships of the life of stokers aboard ocean steamships. A rather intelligent English circus performer, finding himself getting too corpulent for the requirements of his calling and believing that much hard exercise in a very high temperature would rid him of flesh, decided to make the ocean passage as a fireman in a steamship, and obtained the opportunity he desired. The fire room on a steamer is away below the water line, where ventilation is impossible, or at least unattempted. The temperature ranges from 135° to 175°, and in that atmosphere the men are required to shovel coal eight hours in every day — two stretches of unceasing and heavy work of four hours each in the twenty-four. The man in question was advised that he could not stand the exhaustive labor, but he was not to be dissuaded. Several times he fell fainting on the hot floor of the fire room, but always insisted on resuming his duty. When within a day of port, in a fit of mania, he rushed from the heat, climbed to the deck and leaped over the rail into the sea. Sailors rescued him, but he had to be kept manacled during the remainder of the trip.

NEW YORK.

— While a certain evangelist from Michigan, who has been holding a series of revival and "faith cure" meetings at Peekskill on the Hudson, was recently treating Mrs. Julia Hart, of that place, for disease of the heart by anointing and the laying on of hands, the patient suddenly fell backward and almost instantly expired.

— The Charities Commissioners of Brooklyn, three in number, have now been indicted by the Grand Jury for their neglect of the insane under their care, while the Board of Supervisors have been warned that they must take immediate action for the relief of the overcrowded condition of the city asylum at Flatbush. The Commissioners are accused of wilfully neglecting to provide safe and suitable accommodations, care, and attendance for this class of patients. The indictment specifies that they have failed to provide proper means of escape from the buildings in case of fire. Also that some of the insane are compelled to sleep in the cellar, with a totally inadequate provision of competent nurses and attendants, and that the plumbing and the sanitary arrangements of the buildings in general are defective. The indictment was drawn up under the section of the Penal Code (No. 117), which provides that a public officer or person holding a public trust or employment upon whom any duty is enjoined by law, and who wilfully neglects to perform such duty, is guilty of a misdemeanor. A fine of $1,000, or not more than one year's imprisonment, or both, with a forfeiture of office, is the penalty in case the Charities Commissioners should be convicted.

In regard to the Board of Supervisors, the Grand Jury states, in its presentment, that it will be held to be a neglect of duty by the Board should it fail to do all in its power "to remedy the fearful state of the Flatbush institution resulting from over-crowding," and urges the Supervisors to push the completion as quickly as possible of two new buildings which are now in course of erection at St. Johnsland, Long Island. The action of the Grand Jury is largely the result of a night visit recently paid by that body to the asylum at Flatbush, when a thorough examination of the existing condition of affairs was made. The buildings were found to be over-crowded to an unprecedented extent, and some of the unfortunates were quartered in damp rooms and cellars. The sewerage of the institution was ascertained to be especially bad, and it was evident that through its sewerage connections the health of the city of Brooklyn and the neighboring towns was endangered. The Charities Commissioners throw the blame for this disgraceful state of things upon the Board of Supervisors, claiming that they have done all that they could under the circumstances, and that they had not the power, without the sanction of the Supervisors, to make the improvements which have for a long time past been necessary. Among these were included the transfer of a large number of the inmates to the county farm.

PHILADELPHIA.

— Dr. E. O. Shakespeare has returned from India, whither he had been sent by the Government on a special mission to study the etiology of cholera. A reception was tendered to him by his medical friends of Philadelphia and vicinity, on September 30th, at the Hotel Bellevue, which was attended by many of the principal members of the profession.

— With the first week of October, our medical

schools close their preliminary course of lectures and settle down to the regular routine of work for the winter. The introductory lecture at the Jefferson College was given by Dr. William S. Forbes, Professor of Anatomy, on the 30th of September; at the University of Pennsylvania, Dr. E. T. Reichert, Professor of Physiology, delivered the introductory on the 1st of October, and the Medico-Chirurgical College followed on the 4th inst., Dr. William H. Pancoast, Professor of Anatomy and Clinical Surgery, being the orator of the occasion. The introductory at the Women's Medical College was delivered on the 7th, by Dr. William W. Keen, Professor of Surgery. The prospects for large classes of students are said to be better than they were last year. The opening of the clinical lecture course at the Pennsylvania Hospital took place on Saturday, the 2d inst., demonstrations were made by Drs. Arthur V. Meigs and Thos. G. Morton, in medicine and surgery. The remarks of Dr. Morton were important, as he devoted the hour to a consideration of the modern treatment of wounds by aseptic dressings which had revolutionized practice in this hospital. He presented a patient who was well and ready to be discharged, who three weeks before had been brought into the Hospital suffering with a compound comminuted depressed fracture of the skull in the right parietal region. The corrosive sublimate (1-2000) douche was used to cleanse the wound, some fragments of bone lifted and removed, and the wound brought together, and covered with iodoform gauze. There was no rise of temperature, not a drop of pus, and the wound had completely united at the end of twenty-four hours. No symptoms were noticed subsequently. Amputations and compound fractures are dressed with due care to preserve perfect asepsis and left undisturbed for three weeks, when they are usually ready to be discharged. The economy in the matter of bandages over the old method with its daily dressings, is evident, but it is not to be mentioned when we consider the greater safety to the patient and shorter period of stay in the hospital, required by the new treatment. In deep wounds and amputations, carbolized cat-gut filaments are used to obtain drainage from the bottom of the incision of the stump. The results which Dr. Morton presented were strong evidence of the value of the treatment.

Miscellany.

THE CENTENNIAL OF THE ROYAL MEDICAL SOCIETY OF ATHENS, GREECE.

A CIRCULAR, in Greek, addressed to a corresponding member, from the Royal Medical Society of Athens, Greece, announces that the society proposes to celebrate the centennial of its present scientific existence on the 22d and 23d of March next, 1887.

The circular requests the assistance of kindly disposed medical men — by scientific papers, or contributions of interest to the profession; and asks an early communication of titles, etc., that such may appear in the programmes for the occasion.

It is an active and earnest society,— well worthy of high professional regard, and we trust that its request will not pass unheeded; surely some American physicians may be able to give some account of what the profession here has done in the last hundred years, and is still doing.

We shall be happy to be the medium of transmitting any contributions that may be offered.

DIAPHRAGMATIC HERNIA.

THE *Lancet* (Sept. 18) reproduces from *Il Bullettino della Reale Accademia Medica di Roma* (May, 1886, p. 245) a description by Dr. Farraresi, of a diaphragmatic hernia revealed in the necropsy of a young man who had died with symptoms of intestinal strangulation. On surface inspection of the well-nourished body, it was noted that the abdomen was only slightly swollen; the left half of the thorax was broader and more prominent than the right, and the left intercostal spaces dilated. Percussion revealed an area of absolute dullness over the whole left chest, excepting the subclavicular triangle, which yielded tympanic resonance. On opening the abdominal cavity, the coils of small intestine, slightly reddened, presented patches of fine basal injection. Carefully opening the thorax, the left pleural cavity was found filled with a bloody liquid, on giving exit to which the lung, compressed and driven upwards, became visible, the heart being displaced to the right. Besides the liquid already referred to, the pleuritic cavity contained numerous coils of intestine enormously distended, of dull red color; the serous membrane was opaque, rough, and studded with numerous hæmorrhagic spots. The stomach was displaced to the right, with the great curvature turned towards the abdominal wall. Holding aside the stomach and the small intestines, still retained in the abdomen, it was observed that the splenic angle of the colon, and a good part of the jejunum passed into the pleural cavity through a hole in the left inferior half of the diaphragm, at a point corresponding to the normal position of the heart's apex. The descending colon was much contracted. With great difficulty, and after repeated punctures, it became possible to reduce the coil of colon, a piece of omentum, and the displaced small intestine. The hole in the diaphragm was oval, rather more than an inch in diameter, surrounded by a strong, thick, fibrous ring. The gastro-colic omentum which followed the displaced coil was shortened, and adherent posteriorly to the margin of the fibrous ring.

THE LAY PRESS AND QUESTIONS OF PUBLIC HEALTH.

THE *Sanitary Engineer*, speaking of the relation of the daily papers to the accomplishment of sanitary improvements, points out that progress in the improvement of health, the diminution of sickness, and the lengthening of life depends in part on the increase of human knowledge of the laws of physics, chemistry, and biology, and in part on the diffusion among the people of the practical deductions from this knowledge. Sanitary legislation and improvements for any

given community must be regulated very largely by the opinion of the majority of the taxpayers and voters in that community as to the necessity for them, and hence to obtain action for securing a purer water-supply or a better system of sewage disposal, it is not sufficient that a few skilled engineers and physicians are satisfied of the need of the improvement, and of its practicability at a reasonable expense, but the people, from whose hands the funds are to come, must also be "educated up" to the requirements of the situation. This is, of course, a legitimate and an important mission for the public press. That it is often most worthily discharged is thankfully admitted. But that this responsibility is also liable to abuse, is well pointed out by our contemporary.

"The chief defect of newspaper sanitary literature, taken as a whole," it says, "is its tendency to exaggeration and sensationalism, and its liability to be dictated or inspired by a desire for an advertisement. The man who is interested in a patent filter is ready to furnish a column or two on the impurities of the water-supply, with, it may be, a few choice engravings representing strange forms which he tells the shuddering public are entomostraca, desmids, etc. He is careful not to explain that these organisms live in pure water — in fact, that they cannot live in water that is very impure. The man with a patent trap wants to arouse the people to a sense of the dangers of sewer-gas; the dairyman wants to explain the poisonous properties of oleomargarine; the man who failed to get the appointment of health inspector wants to show up the negligence of the health department, and each and all of them do the best they can to get some newspaper to publish their philanthropic essays.

"To those who know how much of this sort of matter is floating round in manuscript form in our large cities the wonder is, not that our newspapers should publish so much rubbish in the way of sanitary letters, etc., but that they should publish so little as they do, and when alarming stories alleging a dangerous condition of the Croton water appear in our daily papers it is safe to assume that the editor has been deceived, or the business department have inserted the matter as 'a reading notice' at so much a line."

CONDITIONS AFFECTING THE GROWTH OF MICROBES IN POTABLE WATER.

The *Polyclinic* for September, discussing this subject editorially, after referring to the increasing importance attached by sanitary chemists of late to the study of organic life in drinking waters over and above that of the mineral or even the decaying organic material, speaks of the method of Koch, which has been made known through the published labors of various workers; this consists essentially of adding to nutritive gelatine, under all necessary precautions, a known amount of water, and placing the mixture so that the existing organisms can multiply. By using a large amount of nutritive gelatine and spreading over considerable surface, each microbe becomes an independent centre of development, and after a time the number of "colonies" can be counted and the mode of growth also noted. Up to the present time the number of facts at our command is not sufficient to give great practical value to this method, since, among other points, it is clear that many species of microbes are harmless or even beneficial. It has generally been held that those which liquefy the gelatine are objectionable, and large numbers, even of the non-liquefying forms, suspicious.

While the practical results, as yet, are not fully attained, valuable information has been obtained as to the changes which various natural conditions, transportation, storage, filtration, etc., exercise on water. The experiments of Percy Frankland and others have shown conclusively that great benefit follows not only the filtering of water, but even the process of subsidence of the solid matter naturally or artificially suspended in it. From observations recently made by Dr. C. Leone in the laboratory of Pettenkofer, it appears that in a drinking water of the highest class, a rapid increase of microbes may take place for a few days. The water which Leone experimented on contained, as drawn from the hydrants, five microbes per cubic centimetre, which in five days increased to hundreds of thousands, and then began to decrease. He found, further, that the presence of free carbonic acid, especially under pressure, almost entirely prevented this increase. Various experiments which are detailed in Dr. Leone's paper (*Archiv. f. Hyg.*, No. 2, 1886, also *Gaz. Chem. Ital.*) indicated that restraining influence was not due to the absence of oxygen, and further showed that certain bottled mineral waters rich in carbonic acid were poor in organic life.

As observed above, continues our contemporary, the facts are not yet sufficient to justify us in founding dogmatic positions; but if observations, of which Frankland's and Leone's are the type, are confirmed and extended, they will be of great utility in sanitary engineering. At the present time, we may say that evidence is to the effect that the most important part of a water-supply system, outside of the all-important point of a pure source, is abundant storage and filtration appliances. There is, indeed, no reason why cities and towns should not be provided with facilities for thirty days' supply at least.

THE MEDICO-LEGAL ASPECTS OF SUICIDE IN LIFE INSURANCE.

We notice an interesting article on life-insurance from a medico-legal point of view by John A. Clark, Esq., in the *Polyclinic* for September, from which we take the following extracts on suicide as related to life risks:

It is almost universally the practice to insert in policies of insurance a clause providing forfeiture in case of "suicide," or of the insured dying by his own hand. The question now arises, how far suicide produced by insanity falls within these exceptions. In England it has been decided that the expression, "died by his own hands," covers all cases of intentional suicide, whether or not the party so dying was conscious at the time of the wrongfulness of his act. This view has been repudiated by the Supreme Court of the United States, which said: "We hold the rule on the question before us to be this: If the assured, being in the possession of his ordinary reasoning faculties, from anger, pride, jealousy, or a desire to escape from the ills of life, intentionally takes his

own life, there can be no recovery. If the death is caused by the voluntary act of the assured, he knowing and intending that his death shall be the result of his act, but when his reasoning powers are so far impaired that he is not able to understand the moral character, the general nature, consequences and effect of the act he is about to commit, or when he is impelled thereto by an insane impulse which he has not the power to resist, such death is not within the contemplation of the parties to the contract, and the insured is liable, nor," said the justice, "do we see any difference, for this purpose, in the meaning of the expressions, 'commit suicide,' 'take his own life,' or 'die by his own hand.'" In New York it has been held that to take a case, on the ground of insanity, out of the proviso, the insured must have been so mentally disordered as not to understand that the act he committed would cause his death, or he must have committed it under the influence of some insane impulse which he could not resist. Of late, insurance companies have endeavored to guard themselves against insane suicide by extending the proviso to read: "If the insured shall die by suicide, sane or insane," etc. It is unquestionable that the companies have a right to insert this proviso, and it has been held that the only construction to be given to these words, is the one that they bear on their face, namely, that the company, in case of a suicide, is to be exempt from all liability; but this does not apply to cases of unintentional self-destruction.

In a letter from Horace Walpole to Bentley, dated January, 1755, we have the following extraordinary story which was told to him in reference to a case of suicide. It appears that at this time there was an office in England for insuring lives even in cases of wilful suicide, but to an amount not exceeding three hundred pounds. A certain man insured his life, and then invited the insurers to dine at a tavern where they met several other persons. After dinner he said to the life and death brokers: "Gentlemen, it is fit you should be acquainted with the company; these honest men are tradesmen to whom I was in debt, without any means of paying but by your assistance, and here I am your humble servant." He then pulled out a pistol and shot himself, thus showing his honesty to his creditors. Similar agreements of insurance, however, have been held void, as against public policy.

Whether death has been produced by natural causes or as the result of suicide, is sometimes a question which has perplexed courts and juries. The burden of proof in all such cases is on the insurer, to show that the death was not natural, but was the result of suicide. The question here arising is one of fact, to be determined by the jury, under the direction of court. If the case is in equilibrium, the presumption is against suicide.

IN MEMORY OF DR. F. H. HAMILTON.

THE Society of Medical Jurisprudence and State Medicine held a meeting in memory of Dr. Frank H. Hamilton, its late president, at the Hall of the Academy of Medicine, September 30th. The opening address was made by the Hon. Amos G. Hull, vice-president of the Society; after which Dr. Charles A. Leale, president of the New York County Medical Association, delivered an extended eulogy of Dr. Hamilton, in the course of which he gave an exhaustive review of his career and his eminent services to surgery and to the profession and society at large. The secretary, Dr. G. W. Wells, then read a tribute to the deceased prepared by Gen. Calvin E. Pratt; which was followed by brief addresses by Drs. Austin Flint, John Shrady, C. S. Wood, Nathan Bozeman, Messrs. Kitchell and Russell, and by other members of the medical and legal professions.

The following resolutions were adopted which were offered by Dr. Leale, who was the chairman of the Committee of Arrangements for the memorial meeting.

Whereas, The medical and legal professions have sustained a sad bereavement in the death of Professor Frank Hastings Hamilton, A.M., M.D., LL.D., late President of the Society of Medical Jurisprudence and State Medicine, which occurred at his residence on the eleventh day of August, 1886; and

Whereas, It is eminently proper for us, in our associated as well as private relations to express our great admiration of the life and character of one who has done so much to elevate Medico-Legal Science, therefore;

Resolved, That as a Society composed of members representing two of the learned professions which he labored so hard to advance and harmonize, we add our tribute of loving esteem;

Resolved, That Dr. Hamilton from his pre-eminent talents, and his position as a teacher, writer and practitioner, covering a period of over half a century, has been the means of deciding many perplexing questions coming properly within the jurisdiction of our Society, and has thereby greatly relieved the professions from the malice of unwarrantable litigations;

Resolved, That the humanity, benevolence and fixedness of purpose exhibited during many years of constant professional toil under numerous trying circumstances, ever with the sincere desire to promote his art and benefit mankind, have ennobled his character, and left to us a name worthy of our highest emulation;

Resolved, That the example of his life, diligent study in early youth, manifest desire to acquire knowledge by carefully searching the Museums of America and Europe for anatomical specimens to settle disputes in surgical pathology, his translations of foreign medical works, his careful and accurate teachings united with a stern integrity ever to be truthful, and last, but not least, his monumental volumes on Fractures and Dislocations which have been the standard works recommended by colleges at home and abroad, and remain to-day unequalled in surgical literature, having been translated into many foreign languages, and are the acknowledged authorities wherever surgery or medical jurisprudence are taught — these with many other honorable characteristics have justly endeared his memory to every true and faithful member of our professions, and placed his name upon the scroll of the illustrious men of the first century of American history.

"Dr. Hamilton," said Mr. Hull, in his remarks, "was a great and good man. He was great because he was good. He was a public benefactor. He was not rich; but, thank God, we are not so degenerate that a man needs to be rich before he can become a public benefactor."

Correspondence.

A HINT TO OCULISTS FROM THE ALMOND-EYED ASIATIC.

MR. EDITOR, — As a hint to oculists and that, too, from our Western neighbors, the Chinese, the following may be of interest:

A Chinese cook in our employ had suffered repeatedly from attacks of conjunctivitis owing to his labors over a hot cook-stove. These were soon cured by the use of collyria of borax and camphor, and a caution as to the real cause. But only to return. To our surprise not long ago he appeared in large Chinese spectacles, tortoise-shell rims and plates of mica, transparent and non-magnifying. With these he goes happily to his work, and so far with no fear of a return of the conjunctivitis, and reasonably too, as mica is notably a protector against heat. Consulting stan-

dard works on ophthalmology I find no reference to their use in occupations exposing one to conjunctivitis from heat, and the idea is certainly worthy of our remembrance.

G. C. SIMMONS, M.D.

SACRAMENTO, CAL., Sept. 26, 1886.

THE REUNITING OF SEVERED DIGITS.

WORCESTER, Sept. 29th, 1886.

MR. EDITOR,— The following case is unique in my practice and may interest your readers.

A young man in a neighboring factory had a finger cut off by a large paper-cutter. He brought the exsanguinated piece to me wrapped up in his handkerchief. It was three-fourths of an inch long, and included the nail and perhaps one-half inch of the last phalanx. With little expectation of success, I adjusted the amputated piece to the stump and now, after ten days, it is firmly adherent, the renewed circulation showing plainly at the finger tip.

Perhaps you can inform me whether such an experience is common. Sincerely,

WILLIAM P. SOUTHER, M.D., Harvard, '78.

[We, in common with others, have frequently heard of such instances, but have never had one occurring in the practice of our personal acquaintances and have never been able to verify such a result. We should be happy to publish any undoubted cases. In the meantime Dr. Souther will not take it amiss if we refer him to a paper on the subject published a year or two since by Dr. F. B. Stephenson, U. S. N.— ED.]

REPORTED MORTALITY FOR THE WEEK ENDING SEPTEMBER 25, 1886.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,274: under five years of age 986: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 530, consumption 277, lung diseases 119, diarrhœal diseases 285, diphtheria and croup 87, typhoid fever 65, malarial fever 39, whooping-cough 21, cerebro-spinal meningitis 16, measles six, scarlet fever six, erysipelas three, puerperal fever two. From malarial fevers, New Orleans 10, Baltimore nine, New York, Philadelphia, Brooklyn and Charleston, five each. From whooping-cough, New York six, Brooklyn and District of Columbia four each, Boston and Baltimore two each, Philadelphia, Pittsburgh and Springfield one each. From cerebro-spinal meningitis, New York and Philadelphia, four each, Fall River three, Baltimore and Cincinnati, one each. From measles, New York three, Boston, Cincinnati and Pittsburgh one each From scarlet fever, New York four, Philadelphia and Brooklyn one each. From erysipelas, Brooklyn, Boston and Cincinnati one each. From puerperal fever, Boston and Worcester one each.

In the 22 cities and greater towns of Massachusetts, with a population of 1,032,650 (population of the State 1,941,465), the total death-rate for the week was 21.50 against 21.47 and 23.61 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,093,817, for the week ending September 11th the death-rate was 22.6. Deaths reported 3,939: infants under one year of age 1 679: acute diseases of the respiratory organs (London) 110, diarrhœa 985, whooping-cough 50, fever 40, scarlet fever 46, measles 38, diphtheria 20, small-pox (London) one.

The death-rates ranged from 13.9 in Bristol to 38.1 in Preston; Birkenhead 24.6; Birmingham 25.9; Hull 27.5; Leeds 26.2; Leicester 34.8; Liverpool 30.4; London 16.5; Manchester 31.0; Newcastle-on-Tyne 27.9; Nottingham 31.9; Sheffield 31.0.

In Edinburgh 16.4; Glasgow 22.7; Dublin 25.9.

For the week ending September 11th, in the Swiss towns, there were 29 deaths from consumption, diarrhœal diseases 26, lung diseases six, diphtheria and croup four, whooping-cough and scarlet fever each two, typhoid fever one.

The death-rates were: at Zurich 13.4; Geneva 12.1; Basle 13.3; Berne 18.2.

The meteorological record for week ending September 25, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps: —

Week ending Saturday, Sept. 25, 1886.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM SEPTEMBER 25, 1886, TO OCTOBER 1, 1886.

BACHE, DALLAS, major and surgeon. Granted leave of absence for twenty-five days, to take effect on or about October 2, 1886. S. O. 143, Division of the Atlantic, September 24, 1886.

APPEL, DANIEL M., captain and assistant surgeon. Assigned to duty at Fort Davis, Texas. S. O. 133, Department of Texas, September 22, 1886.

GANDY, CHARLES M., first lieutenant and assistant surgeon. Assigned to duty at Fort Concho, Texas. S. O. 131 Department Texas, September 18, 1886.

WALES, PHILIP G., first lieutenant and assistant surgeon. Leave of absence extended to include November 5, 1886. S. O. 226, A. G. O., September 29, 1886.

MASON, CHARLES F., first lieutenant and assistant surgeon. Ordered for temporary duty at Fort Verde, Ariz. Ter. S. O. 90 Department of Arizona, September 20, 1886.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING OCTOBER 2, 1886.

GUITERAS, D. M., passed assistant surgeon. To Receiving Ship "Franklin" for temporary duty, October 3.

WENTWORTH, A. R., assistant surgeon. Detached from Navy Yard, League Island, and to the United States Steamship "Galena," October 1.

SCOTT, H. B., assistant surgeon. Ordered to Navy Yard, New York, October 1.

ASHBRIDGE, RICHARD, passed assistant surgeon. Detached from the United States Steamship "Swatara," October 1st, granted six months' leave.

BERRYHILL, T. A., assistant surgeon. Detached from the Museum of Hygiene and ordered to Receiving Ship "Minnesota."

ARTHUR, GEORGE, passed assistant surgeon. Detached from the New York Navy Yard and ordered to the Museum of Hygiene.

PERCY, H. T., passed assistant surgeon. Detached from the United States Steamship "Galena," proceed home and wait orders.

SHAFER, JOSEPH, assistant surgeon. Detached from the United States Steamship "Minnesota," and ordered to the United States Steamship "Swatara."

STEELE, J. M., passed assistant surgeon. Detached from Naval Academy, and granted six months' leave.

BIDDLE, CLEMENT, passed assistant surgeon. Ordered to Naval Academy, Annapolis, Md.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE FOR THE WEEK ENDING SEPTEMBER 25, 1886.

BAILHACHE, P. H., surgeon. Granted leave of absence for thirty days. September 25, 1886.

VANSANT, JOHN, surgeon. Granted leave of absence for thirty days. September 24, 1886.

BRATTON, W. D., assistant surgeon. Relieved from duty on Revenue Steamer "Corwin," ordered to duty at Marine-Hospital, San Francisco, Cal. September 20, 1886.

SOCIETY NOTICES.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT. — THE SECTION FOR CLINICAL MEDICINE PATHOLOGY AND HYGIENE will meet at the *Massachusetts Institute of Technology*, Wednesday, October 13, 1886, at 7.45 o'clock. Prof. W. T. Sedgwick of the Massachusetts Institute of Technology will speak upon "The Filtration of Potable Waters, with Reference to the Elimination of Organic Germs." An exhibition of the most approved forms of Filters will follow the discussion, among others the American Filter, the Cheevan Filter, the Vitrified Filter, the "Filter Rapide," used by Gen. Wolseley in Africa, etc., all of which will be in practical operation. The only Micro-membrane Asbestos Filter in the United States will be exhibited at this meeting. The public is cordially invited to be present.

ALBERT N. BLODGETT, M.D., *Secretary*.
F. I. KNIGHT, M.D., *Chairman*.

GYNÆCOLOGICAL SOCIETY OF BOSTON. — By invitation of Dr. H. O. Marcy and Dr. E. W. Cushing, the next meeting of the Society will be held at No. 714 Main Street, Cambridge, Mass., on October 14th, at four o'clock, P.M. Papers: Dr. W. Thornton Parker, "The Removal of a Large Vaginal Tumor," Dr. W. Symington Brown, "The Rôle of the Ovary."

H. J. HARRIMAN, *Secretary*.

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY. — The Semi-Annual Meeting of the Middlesex South District Society will be held at Porter's Hotel, North Cambridge, Wednesday, October 13, at twelve o'clock. Papers will be presented by: Dr. E. Farnham, "Athletics and Physical Training." Dr. C. H. Cook, "The Physical Education of Girls." Dr. C. C. Foster, "Notes on Caries of the Spine." The Censors of the Society will meet at the same place at eleven o'clock, A.M., of the same day to consider applications for admission to the Massachusetts Medical Society. Dinner at two o'clock, P.M. The telephone number of the hotel is 7294. WALTER ELA, *Secretary*.

BOOKS AND PAMPHLETS RECEIVED.

Galvano-Cautery in Diseases of the Prostate, Bladder and Urethra. By Robert Newman, M.D., of New York. Read in the Surgical Section, at the Thirty-Seventh Annual Meeting of the American Medical Association. Chicago. 1886. (Reprint.)

The Student's Guide to the Practice of Medicine. By M. Charteris, M.D., Professor of Therapeutics and Materia Medica. Glasgow University. Fourth Edition. London: J. & A. Churchill. 1885.

Von Ziemssen's Handbook of General Therapeutics. In Seven Volumes. Vol. V. General Orthopædics. Gymnastics and Massage, by Prof. Dr. Friedrich Busch. Hydrotherapeutics, by Dr. W. Winternitz. New York: Wm. Wood & Co. 1886.

The Healing of Arteries after Ligature in Man and Animals. By J. Collins Warren, M.D., Assistant Professor of Surgery, Harvard University; Surgeon to the Massachusetts General Hospital; Member American Surgical Association; Honorary Fellow Philadelphia Academy of Surgery. One Volume. 184 Pages. Illustrated with 12 full-page plates in black and colors. New York: Wm. Wood & Co.

NOTES ON SYPHILIS OF THE NERVOUS SYSTEM.[1]

BY JAMES J. PUTNAM, M.D.

In looking over the cases of epileptiform seizures with pretty distinct history of syphilis, I find five of which it might at least be said that the symptoms were not incompatible with the diagnosis of true epilepsy without organic cerebral disease, though in most of them syphilis could be fairly suspected.

(1) Male patient; "venereal disease," twenty years ago, during the war; somewhat doubtful history of secondary symptoms; vertiginous attacks with loss of consciousness and followed by headache, about once a month for past year; more or less diffused headache at other times, but no other sign of cerebral disease. (Possibly with a more intimate knowledge of the patient's life other cerebral symptoms would have been noticed).

(2) Male patient; chancre,[2] nine years ago, followed by well-marked constitutional symptoms; typical epileptic attacks with loss of consciousness at intervals during past year, generally at night; frequent attacks of dizziness with buzzing in the ears, but otherwise no sign of cerebral disease.

(3) Male, forty-one years old; "chancre," twenty years ago; scars of apparently syphilitic ulcers over shins; typical epileptic attacks during past eighteen months, always at night; initial cry, loss of consciousness, biting of tongue, attacks sometimes ushered in with feeling of dizziness and "numbness" of hands; great improvement under specific treatment combined with bromide of potassium.

(4) Male patient, thirty-two years old; attacks of loss of consciousness, preceded by sense of dizziness, or indescribable sensation in the head; "chancre" two years ago followed by suppurating bubo.[3]

(5) Male patient, over thirty years old; cannot remember having had chancre, though exposed when a young man; small occipital glands, and one small epitrochlear gland. Two days ago felt tremor of the lip, and put his hand to his face, and then lost consciousness and fell.

Among the "doubtful" group of five cases, the following might be thought to be syphilitic on the grounds above mentioned:

(1) Male patient, thirty-five years old, single; epileptic attacks at intervals of one or more months, night or day, with no aura except slight sense of confusion; no neurotic antecedents. *Sometimes has pain or numbness in first and second fingers of left hand, without loss of consciousness; does not completely lose consciousness in the majority of his attacks; bears well potassic iodide in doses of thirty grains three times daily, and is benefited thereby (in combination with bromides), though he had taken much bromide previously without benefit.*

(2) Married woman of about thirty; personal and family history of perfect health; sudden attack of hemianopsia (permanent) six months before visit; occasional attacks of complete, *temporary blindness, with incomplete loss of consciousness* and sometimes paraphasia; one attack of complete loss of consciousness almost without aura. Husband has ophthalmoplegia externa, and finally admits having had syphilis; general nutrition perfect.

(3) Male, thirty-six years old; married. Illicit connection fifteen years ago, but was never aware of having a chancre. Epileptiform attacks at intervals during past year and a half, lately every few days, *without complete loss of consciousness; insomnia of late*, and *attacks of confusion in head.*

On the other hand there seems no certain way of telling whether the following cases were of syphilitic origin or not:

(1) Male, thirty-seven years old, in perfect health (private patient); gonorrhœa twice but feels sure that never had chancre, and no present signs found; typical, nocturnal epileptic attacks, with sudden loss of consciousness, at intervals of several months for the past six years (under observation and thorough anti-syphilitic treatment for past three years); no present signs of syphilis; moderate improvement under treatment, and moderate tolerance of potassic iodide.[5]

(2) Male, thirty-two years old, of perfect health and good habits; gonorrhœa in his youth but is sure that never had chancre; no present sign of syphilis: two typical epileptic attacks within the past year and a half; recalls that when about twenty years old had some sort of sickness in the night which may have been an epileptic attack.

The six cases in which there was no history or signs of syphilis, nor any reason found to suspect its presence, were as follows:

(1) Female, thirty-five years old; married. Epileptic attacks every two months for past two years, only at night; stupidity and impaired memory for several days after each attack. No history of syphilis, but record of case insufficient to make it of value.

(2) Male, forty-six years old, married. Typical attacks about once a week for four years; no history or sign of syphilis. The record of the case is insufficient absolutely to exclude syphilis, but it is interesting to note that if syphilis was present, four years is a long time for the epileptiform attacks to have occurred without other signs appearing, supposing the disease to have remained untreated which may, I think, be assumed.

(3) Female, thirty-five years old, married. Five attacks of epilepsy within the past two years, always at night; loss of consciousness; convulsion. Has been married seven years, and has four children, all well. No miscarriages; no headache or alopecia; husband living and healthy; fundus oculi normal; no sign of nephritis. Father used to drink to excess, and once had an epileptic attack supposed to be due to that cause.

(4) Female, between thirty and forty years old, married. Typical, severe epileptic attacks with loss of consciousness. No sign of syphilis discovered, although patient remained under observation for several years and did not receive anti-syphilitic treatment.

The attacks were controlled to a considerable degres by the bromides.

(5) Male, between thirty and forty years old, married. Attacks of clouding of consciousness several

[1] Concluded from page 318.

[2] This patient was only twenty-seven years old, and the case is not included in the statistical list.

[3] The diagnosis here is of course doubtful.

[4] H. C. Wood (loc. cit.) records other cases of temporary blindness of syphilitic origin.

[5] Tolerance of potassic iodide is a sign of syphilitic infection which is of only very moderate significance. It is often seen in the non-syphilitic, and with the syphilitic it is often the effect of habit.

times and one attack of complete loss of consciousness with falling. Patient's early history is opposed to the idea of exposure to possible causes of syphilis, and nothing whatever was discovered in his examination to justify that diagnosis.

(6) Male, (physician in large practice in the country), forty-one years old, married. Large numbers of typical epileptic attacks within the past year, usually occurring in groups, and always ushered in by a sense of numbness beginning in the left foot, then passing to left hand and then all over the body. No assignable cause unless it might be a hard, exposed life. Does not admit the possibility of syphilis, and no sign of it discovered.

To these six cases may be added the cases described above, of epilepsy brought on by fright.

Of these six cases of presumptively non-syphilitic origin, one (No. 4). may be thrown out as suspicious because consciousness was incompletely lost.

This leaves but five cases out of upwards of three hundred in which neither the history nor any special sign, except the advanced age of the patient at the time of the first attack, led me to the diagnosis of syphilis, and I have little doubt that more careful research would have reduced the number further, by discovering the presence if not of syphilis, at least of some other special cause, of epileptiform seizures.

While my own experience therefore, corroborates the current view, that true epilepsy does occasionally — perhaps in a few cases out of a hundred — begin in persons over thirty years of age, the rarity of such cases suggests the amount of care that is necessary in making the differential diagnosis, and in eliminating, first syphilis, then lead, next general paresis of the insane and other organic cerebral diseases, chronic nephritis, alcohol and other poisons. The presence of post-cervical or epitrochlear glands, though certainly not incompatible with health, is in my opinion very strong evidence in favor of syphilis, and among the less well-recognized signs, yellowish thickenings on the tympanic membrane, chronic choroiditis and retinitis,— not to speak of acute neuritis — may fairly excite suspicion.

My experience of the past few years has also led me to believe that chronic lead-poisoning may be a commoner cause of adult epilepsy — as it is of so many other nervous diseases — than is usually taught. I believe it to have been the sole cause in two out of the thirty-one recorded cases, beginning at thirty years of age and in another very interesting case of recurrent vertiginous attacks, with loss of consciousness and sensory paræsthesias and marked anæmia, lead was found in the urine, and the patient improved rapidly under potassic iodide. Here, syphilis had also been present, and the etiology was somewhat doubtful.

On the other hand, it seems to me equally clear that cases occasionally present themselves which are in all probability syphilitic, yet which, even after a course of years, present no certain tokens of their origin.

In doubtful cases it may be the physician's duty to use anti-syphilitic treatment, and to continue it, it may be indefinitely, under proper cautions, even though the epileptic attacks continue as before.

My observations throw no light upon the question whether epilepsy may be excited by syphilis without organic cerebral disease.

It is well known that *headache* is one of the most important signs in the diagnosis of cerebral syphilis in the early stages, and it is recognized, though I think not widely enough realized, that syphilitic headache may exist for years without other symptoms, and that these headaches, like those due to tumor of the brain, may simulate typical periodical headaches of other origin. My own experience is in favor of this view. I have also notes of two or three cases confirmatory of a statement made by W. C. Wood [6] that these headaches may cease suddenly on the outbreak of more serious symptoms.

One case was that of a woman, who, when I saw her, had been suffering for days with intense and uncontrollable pain, which suddenly gave place to hemiplegia and aphasia from which she never recovered. In another case of the kind I should certainly try the effect of bleeding, as Dr. Wood recommends.

In another case, the patient, a young man of otherwise excellent health, had long suffered from pain, which he had considered as neuralgic, in a circumscribed spot in the left occipital region, and this too disappeared with the onset of a persistent vertigo. This patient died soon afterward, but not under my care.

It is probable that the headache in these cases is not always of the same origin, and that its sudden disappearance is due to altered vascular conditions, for I have seen the same happen in a case of thrombosis of the left vertebral artery. The patient was an elderly man, and the pain, which had been present for a week or more in the occipital region, ceased on the occurrence of signs of softening of the medulla [7] from which the patient shortly afterwards died.

INHERITED SYPHILIS.

I have endeavored to trace the history of the children of these syphilitic parents for signs of actual syphilis or of impaired vigor, but the data were insufficient for publication. I have, however, notes of one case of what I believe to be inherited syphilis of late development which is worthy of being reported.

It is that of a boy of fifteen, very kindly sent to me by Dr. J. C. Blake, for electrical treatment, on account of deafness, not due to middle ear disease, of only a few months' duration and of rapid increase, and so severe that when I saw him it was difficult to make him understand the voice.

The possibility of inherited syphilis had, I believe, occurred to us both, but was without proof.

Shortly after I saw him, a keratitis developed rapidly in both eyes, without apparent cause. He was sent to Dr. O. F. Wadsworth, and his opinion strengthened the syphilitic theory. The boy was put at once on increasing doses of iodide of potash, which was well borne, and later on small doses of the biniodide of mercury, and he has improved steadily and greatly from that time to the present; an interval of more than a year.

PROGNOSIS.

The curability of syphilitic disease of the nervous system is, I think, usually over-rated. The brilliant results of the first attempts at treatment should not lead one to deceive himself as to the strong tendency to relapse, the necessity of eternal vigilance and of a

[6] Loc. cit.
[7] Confirmed by the autopsy.

persistence in the treatment perhaps throughout the patient's life.[8]

TREATMENT.

I must confess myself decidedly of the party of those who believe that large doses of iodide of potash and mercury are often necessary in the treatment of the late nervous lesions of syphilis, though I must confess that the reasons for my opinion are rather inferential than positive.

Many patients do perfectly well on moderate doses, it is true, and for them possibly enough is as good as a feast. On the other hand, I am convinced that from time to time I have seen patients improve on doses of a drachm or 100 grains of iodide of potash three or four time daily, who had not done as well on smaller doses, and I have seen patients at the hospital that I did not care to trust with large doses, fail to do as well as I thought they ought.

Again, what I think should count of practical importance, I have never seen large doses, properly watched, do any irreparable harm.

In the case of one patient with syphilitic myelitis whom I was seeing daily, and whose prospects of leading a life of invalidism would have made him willing to incur almost any risk, I gave by gradual increase, up to nearly ʒij. of iodide daily, and then for the first time signs of poisoning on the part of the nervous system appeared, which were at first rather alarming, but quickly subsided. I believe that even larger doses than this have occasionally been used. The same patient has been taking now for several years ʒss. or more, daily, for at least half the time, with constant improvent in his nutrition.

RELATIONS OF SYPHILIS TO LOCOMOTOR ATAXIA.

I have notes of fifty cases of locomotor ataxia in which mention is made of the presence or absence of a chancre *judged mainly* by the patient's admission or denial. Of these there was a history [9] of primary infection in twenty-nine cases (male 27, female 2), and secondary symptoms were present, without history of primary infection, in two, and somewhat doubtful symptoms in a third (a female); making in all about sixty per cent. of syphilitic or possibly syphilitic cases. In ten others gonorrhœa was admitted, but syphilis denied, a history which means, at the least, possible exposure to the causes of syphilis.

These figures corroborate the statements of other observers, that there is a close circumstantial bond between syphilis and locomotor ataxia. The nature of this bond no one has been able to discover, but if it proves true, as a few observations seem to indicate, that anti-syphilitic treatment is occasionally effective in bringing about a cure, it will show that the connection is at least occasionally a direct one.

My own experience in this direction, like that of the majority of observers, has hitherto been negative.

It may well be that some of the cases, though presenting the usual symptoms of locomotor ataxia, really belong in another category. Thus, three of the thirty-two patients had shown symptoms of cerebral syphilis, in addition to the spinal symptoms, and with one of these, a woman, the anti-syphilitic treatment seems to have affected the spinal symptoms favorably.

If any advantage is to be obtained by such treatment it probably needs to be thorough and prolonged, instead of incomplete and temporary, as the temptation is to make it.

Strangely enough, the other chronic scleroses of the spinal column do not seem to be, with anything like the same frequency, of syphilitic origin, and yet it does appear to act as one of their occasional causes.

Thus I have seen several cases of multiple sclerosis for which previous syphilis was a possible and the only discoverable cause.

A case of this kind has recently been carefully described by Schuster, in which anti-syphilitic treatment is said to have affected a cure.

Quite as common a cause as syphilis of some forms of spinal sclerosis is chronic lead-poisoning, as I have shown before this Society and elsewhere.

Post-mortem examinations have not as yet shown anything characteristic in the lesions of syphilitic locomotor ataxia.

In a case of my own where the presence of the early and secondary symptoms of syphilis were unquestionable, the spinal lesions did not differ from those ordinarily seen. The arteries in the substance of the cord were greatly thickened, but this may be found in simple tabes.

In conclusion, I beg to acknowledge the courtesy of my colleague, Dr. G. L. Walton, in permitting the use of his notes of cases treated at the Massachusetts General Hospital.

FATAL POISONING BY CHLORIDE OF ZINC APPLIED TO AN EPITHELIOMA OF THE LIP: WITH REMARKS.[1]

BY ARTHUR H. NICHOLS, M.D.

On the 7th of January, 1886, I received an urgent summons to visit J. R., residing in Dorchester. In the month of June previous, this man, whose family I had for many years attended, presented himself for advice regarding an incipient epithelioma situated on the margin of the lower lip. The imperfect development of the growth seemed to render immediate surgical interference unnecessary, and delay was accordingly recommended. This advice did not prove satisfactory, and during the summer he put himself under the care of an irregular practitioner from Worcester, whose treatment proved wholly ineffective. Subsequently, attracted by a mendacious advertisement, and the reputed cure of a neighbor by another irregular physician from Lynn, the latter was called upon, and readily agreed to effect a prompt cure. To quote from this advertisement, now before me, the writer states that he has "a practice peculiarly his own, having never divulged it to any one." He furthermore alleges that "the medicine used is a vegetable liquid, and is a complete and effectual antidote for cancers and tumors, af-

[8] On the reading of this paper attention was directed by a member of the society to the importance of ascertaining, in cases of syphilis of the nervous system, whether the primary lesions had received thorough treatment or not. This inquiry has not been systematically made, but it may be assumed that in the case of the hospital patients there had almost never been a thorough primary treatment, and my knowledge of the history of the private patients enables me to assert the same with regard to the majority of them. The reader's attention is at the same time especially invited to the remark of Dr. J. C. White, (Boston Medical and Surgical Journal of Oct. 7, 1886), that he has seen serious nervous symptoms arise in patients who had been steadily under his own observation and under thorough treatment for upwards of two years following infection.

[9] It is of course probable that the original diagnosis was incorrect in some cases, but these would probably be counterbalanced and more by the cases of mistaken denial of infection.

[1] Read before the Boston Society for Medical Observation, June 7, 1886.

fecting only cancerous tissue. . . . In killing an ordinary cancer, he requires only from two to six hours, and the pain is so slight, a child can easily bear it."

Upon reaching the patient, about 7, P. M., I found him unconscious, respiration slow and stertorous; pulse 110, small and weak; pupils dilated and irresponsive to light; face flushed, and whole body bathed in cold perspiration.

It transpired that at 1, P. M., of that day, a son and partner of this physician, a young man of extremely limited professional attainments, had come to the house and persuaded the family that he was in all respects competent to conduct the treatment, having received the required instructions and remedial agents from his father. The patient's apprehensions were quieted with the assurance, reiterated in the presence of the family, that the medicines employed were purely vegetable, and that the pain produced would be insignificant. The lip was then treated with two different applications, the latter being left bound upon the diseased surface when the young man took his departure at the expiration of about an hour and a half. Three pills (containing, as was afterwards ascertained, one grain each of svapnia) were left, with directions to take them all in case of severe pain.

From the very outset, the patient protested that the pain induced by these applications was unendurable, and it gradually increased in intensity, extending beneath the chin to the neck. These complaints were treated with ridicule by the attendant, who assured him that the drugs used might be even *swallowed* with impunity — a statement which may be important, as tending to throw light upon the real cause of the accident which followed. At about 3, P. M., he complained of the region of the stomach, and soon after rushed to a rear door, seemingly to get fresh air. A violent chill now set in, associated with a numbness of the lower extremities, and a sensation of dizziness. He was then assisted to a lounge, and the plaster removed from his lip. Convulsive movements of the upper extremities now supervened, and he soon sank into a state of stupor, followed by coma, from which he could never after be aroused.

Medical aid was now sent for, and Drs. C. E. Stedman and W. C. B. Fifield were soon procured. The prominent symptoms observed by these gentlemen upon their arrival were stupor, retarded breathing, and unevenly dilated pupils; and under the influence of heat and stimulants, there was for a time marked improvement in both pulse and respiration, while the pupils regained their normal calibre. When it was ascertained, however, that the opiate pills had not been taken, it was deemed expedient to telegraph to Lynn, with the view of eliciting precise information as to the nature of the poison which was producing so profound an effect upon the nervous system. This message was responded to by father and son, who appeared upon the scene about 8.30, P. M. The latter, upon his arrival, was rendered rather incoherent by the ghastly appearance of the patient, now rapidly sinking, and he was shortly after led from the room in a demoralized state. The father succeeded in maintaining a better equilibrium, and volunteered the following details as to the treatment adopted: The procedure consisted, as alleged by him, in the application of a strong potash lotion, made from lees formed of the ash of sweet-fern and bayberry tops, designed to remove the cuticle. The tumor proper was then attacked by a caustic paste bound upon its surface, prepared according to the formula:

℞ Zinci chloridi	ʒ j.
Amyli	ʒ ij.
Podophyllin	℈ ss.

By 9, P. M., the pulse was 140, very weak and intermittent, and death ultimately ensued at 9.30, P. M., from asphyxia, the pulse and heart-beat being perceptible fully eight minutes after voluntary respiration had ceased.

The patient whose life was thus abruptly terminated was a robust, rugged farmer, aged fifty-two, of steady, temperate habits; he had been in perfect physical condition up to the very day of his decease, with the exception of an occasional slight attack of neuralgic rheumatism. These periodic illnesses had excited some suspicions on his part as to the existence of kidney or heart disease, on which account I had from time to time examined him, and retain the record of several analyses of urine. The result of these examinations had led to the conclusion that he was free from all organic disease — an opinion confirmed by a careful *post-mortem* made by Dr. H. Warren White.

"*Autopsy.* Sixteen hours after death. Well-developed man, past middle life; cadaveric rigidity well marked. Dark, circumscribed discoloration of lower lip on left side; surface nearest the teeth ulcerated; not much infiltration. Skin, fatty layer scant. Musculature firm developed; good color. Brain, veins prominent; no signs of hæmorrhage, tumor, softening, inflammation, nor anything abnormal. Heart, left side moderately hypertrophied, blood fluid, valves healthy. Lungs, some hypostatic congestion, but remarkably free from adhesions or any morbid process. Liver, fair size, slightly congested. Gall-bladder partly filled, normal. Spleen somewhat softened and congested. Stomach moderately distended with gas lining membrane perfectly normal. Œsophagus normal, save a congested ring about one inch above the cardiac orifice, possessing no significance. Intestines distended, vermiform appendix of above average length, and containing a small concretion; color everywhere normal. Pancreas normal in size and appearance. Kidneys healthy; normal relation between cortex and pyramids; cyst of the size of a filbert at apex of right kidney. Bladder full of urine; opened and found healthy. Intestines free from constrictions and other lesions."

If we accept the statement of the attendant and family concerning the treatment and subsequent behavior of this man, it is highly probable that death was due to the absorption by the *primæ viæ* of a portion of the strong mineral caustic (chloride of zinc), which trickled into the mouth from the plaster applied to the margin of the lip, the ingested poison proving fatal by the profound shock exerted upon the nervous system.

Nor is this theory of the specific action of the irritant poison invalidated by the absence of marked erosion or irritation of the mucous membrane of either mouth, œsophagus or stomach, which effect would not be produced if the poison entered the mouth slowly, receiving thus a large admixture of saliva. It seems, indeed, unaccountable that any appreciable quantity of so metallic-tasting a substance could have entered the mouth during consciousness without being promptly rejected; or, at least, without exciting some complaint. Attention may, however, have been diverted from the internal, local effect, or disagreeable taste, by the false assurance that the drug could be safely

swallowed: or, possibly, by the more painful action of the caustic upon the healthy tissue surrounding the diseased growth.

It was my privilege, as a medical student in Paris in 1864, to witness the experiments conducted by Maisonneuve in the treatment of carcinoma, scirrhus, and other recurrent and fibrous tumors by the so-called *cautérisation en flèches*, introduced by him in 1858. This treatment consisted in thrusting caustic arrows into deep incisions made with the bistoury in the periphery of the mass to be removed. In the course of twelve or fourteen days the diseased structure was destroyed and detached, leaving behind a clean, healthy surface, which became speedily cicatrized. These arrows were used not only in the case of morbid growths upon the surface of the body, but also in tumors of the neck of the uterus, the tongue, soft palate, tonsils, anus and rectum.

It was claimed by this surgeon, that while the styptic action of the caustic prevented all danger of hæmorrhage, its destructive action was confined to the diseased tissue in its immediate contact. The statistical results of this method, extending over a series of years, seemed to demonstrate its effectiveness; and that it lessened the danger of erysipelas and pyæmia at that time rife, owing to the insanitary condition of the Paris hospitals. I saw enough to convince me, however, that the pain produced by this process was immeasurably worse than that inflicted by the knife, and, of course, of much longer duration. The formula then employed by Maisonneuve was: — chloride of zinc, one part; wheaten flour, three parts; water, sufficient to make a paste. From this paste, rolled into a thin, round sheet, arrows of any dimensions could be cut. It will be observed, that the chloride of zinc used in the present case was identical in strength with that recommended by Maisonneuve.

As regards the medicinal use of this agent, it has been employed, largely diluted (m. x–xx to ʒiv), as an urethral and vaginal injection; also as a collyrium in gonorrhœal and diphtheritic ophthalmia. It was at one time exhibited internally, especially in France, in small doses (5 to 10 centigrams a day), on account of its alleged antispasmodic action in certain nervous derangements such as chorea, epilepsy, hysteria and neuralgia; but was discarded on account of its uncertain therapeutic effect, and because of the deleterious results observed (colic, nausea, vomiting, convulsive movements, etc.)

As an external application, it was first used by Pappengath, a St. Petersburg physician, in the obliteration of fistulous ulcers of a scrofulous nature. Subsequently it was recommended by Hancke for the destruction of maternal nævi, syphilitic ulcers of carcinomatous appearance, etc. By various German writers (Moore, Reichel, Heine), it has been praised as a caustic injection. Lutin advises an aqueous solution of five to even ten per cent. in order to establish sloughing. In Hebra's wards in Vienna, in 1867, *lupus* was occasionally treated by means of a modified Canquoin paste, the active ingredients of which were chloride of zinc and chloride of antimony: and I find in my note-book a formula, recommended for cancerous tumors of the breast, composed of chloride of zinc combined with chloride of bromine and chloride of antimony.

I have found but a single clinical fact to support the statement of Orfila as to the possibility of the absorption of this substance by a denuded surface. In *Pyl's Memoirs* a case is recorded (referred to by Naunyn, also by Woodman and Tidy), where the outward application of chloride of zinc to an eruption is said to have caused death in five hours with vomiting, purging, and convulsions. I have sought in vain for the work here alluded to, and find it difficult to accept a statement so utterly at variance with universal experience.

In the light of existing knowledge we are not, therefore, in condition to condemn the remedial agents resorted to in the present instance; for the caustic was employed in justifiable strength, and substantially as has been recommended by surgeons of repute. The malpractice consisted in the failure to employ ordinary and reasonable care in the management of the case, and in the deceptive statements as to the innocuousness of the drugs. The doctor was unfortunately ignorant of the toxical effect of his remedy when taken internally; and the patient, lulled into false security, thus failed to take the necessary precautions as to allowing the poison to enter the mouth or stomach.

Poisoning by chloride of zinc, though formerly unknown, has been comparatively frequent in England, since the introduction of Sir William Burnett's disinfecting fluid, which contains about two hundred grains of the salt to the ounce. More recently, cases of poisoning have occurred, both in this country and abroad, from the use of canned vegetables and meats containing a small quantity of chloride of zinc dropped into the cans from the soldering material applied to secure the lid. If the dose of the poison administered be large, death ensues ordinarily within a few hours from its irritant or corrosive action: characterized by a burning sensation, colic, vomiting, diarrhœa, cramps and convulsions. If, on the other hand, the poison be taken in smaller doses, or less concentrated, so as to be absorbed; or, if the patient does not at once succumb to the primary corrosive action, then the secondary, specific effect if the drug upon the nervous system is manifested; indicated by venous congestion, stupor, dilated pupils, convulsive movements, paralysis, and coma, a group of symptoms resembling those of uræmic poisoning. This compound toxical effect is more frequently witnessed in certain poisons derived from the vegetable kingdom, such as *nux vomica*, hemlock, monkshood, veratrine, and poisonous mushrooms.

I am inclined to believe that the behavior of the pupils under the influence of this poison may not be constant nor characteristic, although dilatation is the condition commonly noticed; for it is not assumed that this change in the iris is essentially the result of a local action upon the muscular fibres or blood-vessels of this organ such as is produced, for instance, by belladonna: it is rather to be included in the category of the familiar phenomena liable to follow any sudden and severe disturbance of the central nervous system, the rationale of which phenomena is by no means clearly understood. Hence, it would not be strange, if, as in some instances of traumatic shock, the contracted pupils, or so-called pupils of erethism, were at times observed.[2]

The first reported instance of fatal poisoning by chloride of zinc is that related by Dr. Letheby, former lecturer on chemistry in the Medical School of the London Hospital, and to show that this dual action of

[2] Vide Grœningen, Ueber den Shock, p. 86.

the drug was fully recognized and accurately described by this distinguished writer, I may reproduce in synopsis his article.[3]

The patient, a girl aged fifteen months, "when first seen was in a semicomatose state, the vital powers being much prostrated, the countenance pale and anxious, the breathing thoracic and rapid, the pulse quick and fluttering, and the general surface of the body cold and bedewed with perspiration. The swelling of the lips and the thick, transparent mucus adhering to them, led to further examination, and the lining membrane of the mouth was found to have the appearance of having undergone the action of a corrosive substance. The child had been well in the morning, and only an hour and a half before had been seized with most violent sickness after swallowing some of Burnett's fluid. . . . No relief could be given; vomiting of a frothy liquid took place at intervals, but the coma became deeper, the respiration slower, the pulse more feeble, and ten hours after the symptoms had commenced the child died."

Experiments made by Dr. Letheby with this liquid in order to determine its leading chemical and physiological characters, showed: firstly, That chloride of zinc is distinguished from the other salts of this metal by its quick and firm coagulating action on liquid albumen and on the delicate tissues of the body. Secondly, That a solution of chloride of zinc exerts a twofold action on the living animal economy. Its first effect is that of an irritant and caustic; the liquid coagulates the tissues and gives pain in the part to which it is applied, and causes almost instantaneous vomiting. It appears moreover, from the investigations of Orfila, that the salts of zinc act upon the stomach not only when they are introduced into this organ, but also when they are injected into the blood-vessels of the body. The second effects are of a constitutional character, and it would appear that the poison exerts a distinct and specific action on the motor and organic system of nerves; for soon after the poison gains access to the circulation, the breathing and pulse become accelerated; paralysis of the voluntary muscles commences; the surface of the body grows cold, the pupil is dilated; the circulation and respiration become more and more affected, coma supervenes, and death takes place without a struggle.

Dr. Letheby proved, moreover, by experiments, that the poison is absorbed from the alimentary canal and carried into the general circulation. He has detected the metal in the blood removed from the heart, in the tissues of the body, and in the urine excreted during life. The appearances presented by the blood indicate that the poison exerts some peculiar action on this fluid, which is found black and uncoagulated; and the cavities of the heart are distended as if the organ had lost the power of contracting on its contents.

To Dr. John G. Johnson, of Brooklyn, belongs the credit of first directing public attention to the danger arising from the use of fruit and vegetables preserved in cans, the lids of which have been soldered with chloride of zinc instead of resin; and he has, furthermore, demonstrated that it is impossible for the most expert workman to employ this objectionable solder without dropping some portion of it into the can. In the *Sanitarian* for June, 1884, he gives a most instructive account of the poisoning of six persons in one family from this source. These cases having been made the subject of subsequent litigation have attracted extensive notice, and are of especial value in that they illustrate the compound action of the drug in a single subject.

In a more recent contribution to this same subject,[4] Dr. Johnson propounds the novel theory, that a still more subtle form of poisoning resulting from the continued use of these canned goods may consist in a chronic disturbance of the renal functions (nephritis) accompanied by albuminuria, and ultimately giving rise to a form of Bright's disease. This theory, though not yet demonstrated by clinical observations or physiological experiments is certainly in accord with the more recent hypothesis framed to explain some of the phenomena of lead poisoning (*amaurosis, retinitis, nephritis, etc.*) in which the retention of the constituents of the urine and the concomitant accumulation of the poison may give rise to symptoms resembling in their ultimate development those of uræmic poisoning.

As regards the legal responsibility in this case, where death was presumptively owing to the treatment received and caused by it, there cannot be much doubt as to the criminal liability of the delinquent practitioner for the injury thus caused. Indeed, two successful actions have recently been sustained in this State, in which the negligence or culpability was certainly no greater than in the present instance; that of Pierce, who caused the death of a woman by the application of kerosene, and that of the woman-practitioner Cummings, whose negligence and recklessness in the use of the fluid extract of the St. Ignatius bean led to a fatal result. The principle of law laid down by the court in these cases is, that if a person publicly practising as a physician, on being called to a sick person prescribes with foolhardy presumption a course of treatment which causes death, proper medical assistance being at the time procurable, he may be found guilty of manslaughter, although he acted with the patient's consent, and with no ill intent.[5]

In the case of Pierce, it was held by the Supreme Court that the defendant's knowledge or ignorance of the fatal tendency of the prescription did not have an important bearing upon his guilt or innocence; inasmuch as every physician is supposed to possess a familiarity with the remedies which he employs; and if any one assumes to prescribe without the exercise of ordinary prudence, and, not being in the possession of common experience, thereby seriously and unreasonably endangers life, he does so at his peril.

To quote the apt illustration of Judge Holmes: "When the jury are asked whether a stick of a certain size was a deadly weapon, they are not asked further whether the defendant knew that it was so. It is enough that he used it and saw it such as it was. . . . Indeed, if the defendant had known the fatal tendency of the prescription, he would have been perilously near the line of murder."

This is now the law in Massachusetts, and it is in harmony with the English law, as well as with a multitude of decisions in other States; and the rule, while working no harm to the competent physician exercising his calling with reasonable diligence and care, must conduce to the safety and welfare of the community, in so far as it assigns some limitations to

[3] *Vide* Lancet, June 11, 1859, p. 23.

[4] New York Medical Journal, April 24, 1886.

[5] Mass. Reports, 138, 165.

the license of reckless pretenders. It is uncertain, whether it was the recognition of this liability, or a dread of exposure which led the principal in this fatal experiment to settle with the family of the victim without allowing the case to come to trial.

There exists in every community a class of sufferers, who, in consequence of some previous fright or personal idiosyncrasy, entertain a morbid dread of any operation involving hæmorrhage, and who prefer therefore to submit to pain, rather than to the surgeon's knife. Such persons are surely not to be blamed if they elect treatment by caustic rather than by surgical operation, when it has been asserted by competent surgeons who are supported by official statistics, that not only does the caustic promise a result equally favorable to that obtained by excision, but, moreover, that the morbid growths are more thoroughly reached and their recurrence thereby rendered less probable.

It is, therefore, to be regretted, that so many patients are compelled, in order to obtain relief by this method of their choice, to resort to non-reputable practitioners, because the legitimate treatment by caustics formerly so highly commended has by reason of fashion, or from other insufficient causes, been substantially discarded by the regular profession.

TENDERNESS OF THE SPINE IN HEALTH AND DISEASE, AND THE THERAPEUTIC EFFECTS OF BLISTERING OVER THE FOURTH AND FIFTH DORSAL VERTEBRÆ.

BY MORTON PRINCE, M.D.
Physician for Nervous Diseases to Out-Patients, Boston City Hospital.

In an article published not long since in the *Lancet*,[1] Dr. Alexander Harkins, of Belfast, calls attention to a phenomenon which he claims, as a result of very extended observations, is normally to be observed in every individual; namely, tenderness on percussion over the fourth or fifth, or both, dorsal vertebræ. Dr. Harkins at first thought that this was peculiar to women suffering from various neuroses, but after examining the spines of a large number of people of both sexes, he concluded that tenderness of one or both of these vertebræ was the normal condition of every individual of every age and class. Of one hundred and thirty-one female children and girls, from six to sixteen years of age, every one complained of tenderness in this region when the spines were percussed. Of thirty-five women, of various ages, the phenomenon was present in the greater number, while "a number resented the examination, were sulky or gave indifferent answers." Of thirty-one boys, eleven to nineteen years of age, and of three hundred men, tenderness was observed in every case. The pain was said to be peculiar; "some compared it to an electric shock, diffused over the chest and arms; others liken it to the tingling sensation caused by a knock upon the ulnar nerve, at bend of elbow, and all declare it disagreeable."

Dr. Harkins further claims that he has constantly been enabled to cure a large number of neuroses by the simple method of placing a blister over the tender spot. The vomiting of pregnancy seems especially to have been amenable to this treatment. "I have not once failed," he writes, "for many years by a single vesication over these vertebræ, to put an end at once to the sickness of pregnancy, for the whole remaining period of gestation, no matter at what stage I was consulted. The neuralgic toothache, and the pruritus pudendi of the puerperal condition yield as readily to one application." Dr. Harkins's paper contains the notes of a number of cases in which a cure was speedily affected. They include, besides the neurosis of pregnancy, chorea, facial paralysis, facial spasm, neuralgia, ozœma, and dysmenorrhœa.

The great care with which Dr. Harkins's observations have been made and recorded entitle them to something more than passing attention, and it is evident at once, that if they should be confirmed, they must be of great practical value. Tenderness over some part of the spinal column is generally regarded as symptomatic of a number of nervous disorders. Every one, probably, has carefully percussed a multitude of spines and gravely recorded the tender spots in his note-book. But if it be true that we all are the possessors of a tender spot, such tenderness, when associated with disease, would lose much of its pathological significance, at least when located over the fourth or fifth dorsal vertebræ.

Even in so-called spinal irritation, local tenderness, which has played such a prominent part, must lose much of its diagnostic value, and even some of its power as a claimant for sympathy for the sufferer.

Furthermore, if such remarkable therapeutic effects can be obtained by such a simple procedure as blistering in the above described fashion, we have a powerful remedy at our disposal for many intractable diseases.

Accordingly the writer set about percussing the spines of a number of healthy and unhealthy individuals, and blistering such unhappy ones as promised to be good subjects for experiments. Though the results obtained have not completely confirmed those obtained by Dr. Harkins, they appear to be sufficiently striking to be worth recording, and to be not devoid of practical value. They seem to the writer to aid in giving the proper value to spinal tenderness as a symptom, as well as to a therapeutic procedure which in suitable cases must prove of unquestionable utility.

First, the spines of 57 healthy men were percussed. In 53 of these no tenderness whatever could be detected. Two, only, complained of tenderness over the fourth and fifth dorsal vertibræ, while one stated that the third dorsal, and one the tenth and twelfth dorsal were tender.

To avoid error more force was used when striking over the vertebræ in question than over the remainder, though all were struck with considerable force. As a percussor, the knuckles of the forefinger were used, the fist being firmly clinched; sometimes a percussion hammer was substituted, often both were tried. The subjects were stripped to the waist and put in a favorable position for the experiment.

The subjects of experiment were applicants for position on the Boston Fire Department, and it occurred to me at the outset that the results obtained might be affected by the men denying all tenderness, for fear of appearing unsound. To offset this, as a source of fallacy, I impressed upon their minds the object of the examination, and even insisted that every healthy man ought to have a tender spot in his spine. But it was all to no purpose. Even after making a

[1] 1883. v. ii., pp. 56 and 995.

liberal allowance for this possible source of error, the results, to be presently described, obtained on men sick with various diseases, show that there would still remain a large variation from Dr. Harkins's results.

Why his and mine should be so at variance, especially those obtained with the Irish constabulary, I am unable to understand, unless indeed, the strength of the official Irish backbone has been somewhat weakened of late by apparitions of coming home-rule. I have had no opportunity to test the spines of any large number of *healthy* women. It is very likely that tenderness is sometimes present, but that it occurs with anything like the frequency that has been asserted, may be strongly questioned, inasmuch as none whatever could be detected in a large proportion of women debilitated by various diseases.

Coming now to the condition of the spinal column in disease, I have notes of 75 cases, which were examined without selection and in their order of appearance at the out-patient nervous department and wards of the City Hospital. They embraced quite a variety of diseases.

Of the total 75 patients, 37 were males, affected with the following diseases: epilepsy, neuralgia tabes dorsalis, multiple sclerosis, neurasthenia, chorea, hysteria, hemiplegia, myelitis, neuritis, traumatic paralysis, articular rheumatism, heart disease, typhoid, pneumonia, nephritis, pleurisy, debility, gastritis, phthisis, cystitis.

In 20 of the 37, tenderness over either the fourth or fifth, or both dorsal vertebræ could be detected; in the remaining 17, these vertebræ exhibited nothing noticeable whatever.

The women included about the same class of cases, and were 38 in number; in 24 of them tenderness was complained of in the fourth and fifth dorsal vertebræ, a proportion slightly in excess of that obtained with males. The absence of tenderness in the region in question in fourteen cases shows that, at least in the writer's experience, this is not a constant phenomenon, even in disease. The nature of the disease does not seem to have any influence. It was found in organic as well as functional, in non-nervous as well as nervous diseases; nor is it always present in any one disease. It would seem that anything which tends to debilitate the system may give rise to the phenomenon, especially phthisis.

On the other hand, the character of the pain was not described as like that given by Dr. Harkins's subjects, but only as a local, ordinary pain. In only one case (of pregnancy not included in the above) it was referred to the stomach, and described as sickening or nauseating.

It should be said that the pain spoken of in many of the cases was slight, in some so slight that it would not ordinarily be recorded; but as there is no way of measuring the degree of pain, all such cases have been counted among those with tender spines. But it is not always in the region of the fourth and fifth dorsal vertebræ that tenderness, when present, is located. Of the 37 men examined, general tenderness of the spine was noted in 4 cases, and tenderness other than over the fourth and fifth dorsal in 11 cases (with or without coincident tenderness in the latter locality). Of these 11, it was located over the first dorsal in 1 case, second dorsal 2 cases, sixth dorsal 1 case, and eleventh dorsal to first or second lumbar in 7 cases; so that next to the fourth and fifth dorsal, the next most common site is the dorso-lumbar region. In only 11 out of the whole 37 cases could no tender spot at all be detected.

No note was made as to the existence or non-existence of tenderness in the women other than over the fourth and fifth dorsal.

Coming now to the therapeutic effect obtained by blistering over the fourth and fifth dorsal vertebræ in neuroses, the results cannot be said to be as successful as claimed for the treatment by Dr. Harkins. In a few instances they were striking, and showed the method to be of some practical value. It was applied in quite a variety of functional and organic nervous affections, such as chorea, neurasthenia, neuralgia, paralyses, vomiting of pregnancy, torticollis, spinal irritation, rheumatism, tobacco-neurosis, etc.

The most strikingly successful case was that of a woman of about thirty to thirty-five years of age, who had been under treatment in the surgeon's room at the Dispensary for about four or five weeks, without any improvement. She was finally brought to me. At this time she complained of great pain and tenderness in the back of neck, the pain shooting upwards over the back and sides of the head. The muscles of the neck were stiff, almost rigid, the head being fixed in one position. There was great tenderness over the cervical vertebræ, and the slightest jar on the top of the head or movement of head caused intense pain; indeed it had been thought there might be caries of the vertebræ, especially in view of the physical condition of the woman, which was that of anæmia and debility. Her expression was indicative of prolonged suffering. There was also enlargement of the submaxillary glands. Finding, also, tenderness over the fourth and fifth dorsal vertebræ, I directed that a blister be placed over that region.

The next day the woman returned, presenting an entirely different picture. The pain and tenderness were gone, the motion of the head was natural, and the look of suffering had disappeared from the face. Of course, the pleasure exhibited by the patient at being at last relieved from pain was what might have been expected. She afterwards had some trouble with the enlarged glands, but the above symptoms never returned. I saw her about a year afterwards, when she stated she had had no return of the symptoms. Two other cases of the same character but less severity were equally successful. One was that of a man whose surprise and delight at his sudden cure were truly comical. I have tried the treatment in one case only of vomiting of pregnancy, when it was eminently successful (vide *Boston Medical and Surgical Journal*, 1886).

In a case of paralysis and atrophy of the deltoids, biceps, brachialis anticus and coraco-brachialis of both sides, accompanied with intense pains about the shoulders, arms, and neck, I found the spine exceedingly tender in the fourth and fifth dorsal region. The case was probably one of progressive muscular atrophy. For the relief of pain, I blistered with the actual cautery in the above region. The effect was to give great relief from pain, but none on the course of the disease was noticed. The cautery, from time to time, had to be repeated. Some improvement followed the treatment in a case of spasmodic torticollis, and in one of "nervous excitability" from excessive use of tobacco. The neuralgic pains of spinal irritation were also relieved by blistering.

On the other hand, in all organic diseases, such as tabes and neuritis, it has naturally failed to produce any curative effect. In chorea, my experience has been opposed to that of Dr. Harkins, as I have failed to obtain any improvement, unless it be, as is possible, that some of the cases which did not return for a second observation were benefited, and for this reason did not return. This was the case with a number of patients with various ailments, and as a single visit is not the usual failing of patients attending nervous clinics, it is not a very extreme assumption to suppose some of them were cured. In the majority of cases, certainly, the treatment was without success. Whether or not a blister over the fourth and fifth dorsal vertebræ has any specific influence, or more than over any other portion of the spine, or elsewhere, I refrain from discussing in the absence of sufficient data.

Finally, from what has been said, the following conclusions may be drawn:

Tenderness over some portion of the spinal column is not peculiar to any particular class of diseases, but may be present whenever the system is debilitated from any disease. It may be met with in health; it is more frequent over the fourth and fifth dorsal vertebræ than elsewhere. Second, decided and beneficial effects may often be obtained by blistering over the fourth and fifth dorsal vertebræ in various neuroses.

Clinical Memorandum.

A CASE OF PUERPERAL ECLAMPSIA.[1]

BY SARAH ELLEN PALMER, M.D., OF PORTLAND, ME.

Mrs. W. B., primipara, thirty-nine years of age, married sixteen months since. Six years before her marriage she had left the school in which she taught because of a serious illness, beginning with sudden unconsciousness, while leading the school exercises. Of this illness I have no medical account. With this exception she had never been ill, save occasional attacks of facial neuralgia.

During the first eight months of pregnancy, the health had been perfectly good, save an annoying eczematous eruption on the legs, which yielded to simple remedies and partial rest; no swelling of the feet followed. In November, when eight months pregnant, she suffered from an attack of tonsillitis, succeeded, before she was fairly well, by a mild form of diphtheria. From this she made a perfect recovery.

The patient was dismissed December 15th, the house thoroughly disinfected, and the drainage investigated. At this time the urine was examined, as it had been thrice before; then, as now, the kidneys were found in a perfectly normal condition. At the time of confinement the feet were slightly swollen and œdematous, but the ordinary boots could be worn.

Friday, January 8th, I was summoned at 5, A.M. The cervix was shortened, but not obliterated. At 3.15, P.M., she was delivered of a boy weighing seven pounds. The placenta followed at once. The labor was normal, though slow, and the patient's strength good throughout. The uterus contracted well. During the second stage the pains, though effectual were separated by a considerable interval; ether was given to dull the sensibility, but not to unconsciousness, and with no effect on the efficiency of the pains. One drachm of Squibb's fluid extract of ergot was administered on the expulsion of the head from the cervix, and again just before delivery. During the progress of the labor, the bowels were evacuated, and the urine was drawn with a catheter in the second stage. After labor the patient was in good condition, expressed herself as feeling well, and took some nourishment. Thirty minutes from delivery, she shivered and said she felt "nervous, not cold." Before I could reach the bed she was in a clonic convulsion, almost immediately tonic in character. The uterus, held by the hand of my assistant and well contracted, now relaxed; the pulse at the left wrist was imperceptible, the right was not examined; blood issued from the mouth. Stimulant injections of brandy and ether were given hypodermatically; the pulse weak and rapid, appeared at the wrist, and the uterus contracted in response to a hypodermatic of ergot. Convulsive motions continued about one minute and a half, followed by unconsciousness for thirty minutes. The face, hands and feet were almost immediately perceptibly swollen. Dr. I. T. Dana, of this city, came in consultation, and the following treatment was given by common consent. Because of an idiosyncrasy, morphia was sparingly given; one-third of a grain was injected with the hypodermatic syringe, and this was repeated twice during the next two days. Pilocarpin, one-eighth grain, was also given hypodermatically. The urine, drawn with the catheter, became almost solid on boiling, and from a specimen sent a few hours later to an accomplished specialist, the following report was received: Appearance of the liquid yellow, turbid, with a considerable sediment; reaction neutral; specific gravity 1.024; loaded with albumen. The microscope showed urates of ammonium, triple and simple phosphates; epithelia from the vagina, bladder, convoluted tubules of the kidney and pelvis and cervix uteri, with hyaline and granular casts. A diagnosis of acute catarrhal and croupous nephritis, with a grave prognosis, was added by the microscopist.

Upon recovering consciousness after the first convulsion, the patient answered Dr. Dana's greeting, and was immediately seized with a second attack, which was shortened by the administration of ether by inhalation. At this time the pulse was distinct at both wrists. During the following hour, two impending convulsions were aborted by the ether. During the day two drops of croton oil in one teaspoonful of castor oil placed on the tongue were followed by a free and apparently involuntary evacuation from the bowels.

Immediately after the first convulsion, forty grains of bromide of sodium were given by rectum. Six hours later, thirty grains of bromide with fifteen of chloral were injected.

During the day the patient recognized those about her and responded to simple questions; in the afternoon she seemed to hold a most vivacious and pleasing conversation with some invisible person. Towards night she fell into a semi-conscious state. Dr. Gerrish, who was now added to the consultation, was apparently recognized as he entered the room and greeted Mrs. B. Later the face assumed a dusky hue, and although she opened her mouth in answer to a request to protrude the tongue, she made no further

[1] Reported to the Practitioner's Club, June, 1886.

effort. From this time the mental condition steadily failed until at twelve o'clock she was unconscious. The teeth were set firmly, the eyes were closed, the face was dusky and swollen, the respiration was Cheyne-stokes, the pulse was rapid, and the temperature was 101.5° F. During the afternoon, digitalis had been administered, and a sinapasm applied over the upper cervical region. At 12.30. A.M., the teeth were forced open and whiskey and beef tea poured down the throat. Sunday at 2, A.M., thirty drops of dilute phosphoric acid was injected with the hypodermatic syringe, and repeated every thirty minutes until four doses had been given.

From this time she very slowly improved, and at 5, A.M., was sleeping quietly, with respirations more regular, and the dusky hue of the face slightly lessened. During the day dilute phosphoric acid was given by the mouth in fifteen-drop doses every three hours, the amount given being regulated by its apparent effect on the head. We judged of her sensations simply by her involuntary movements. During the morning she was in a semi-comatose condition from which she gradually aroused, but with evident aphasia which did not disappear until Tuesday morning, when she could, for the first time in sixty hours, frame intelligible sentences, seventy-six hours from the first convulsion. She talked very slowly at first, and was fatigued by the effort. She had no recollection of anything which occurred after the appearance of Dr. Dana, thirty minutes from the first attack. During this interval, beef-tea, whiskey and milk were freely administered; dilute phosphoric acid was given with the caution mentioned above, and tincture of digitalis.

The urine was passed with the involuntary dejections, and therefore the amount could not be exactly estimated, but it was drawn every six hours, and the quantity was nearly normal. Microscopical and chemical examination at this time showed the specific gravity to be 1,016, with the albumen slightly lessened and the casts fewer; but a large quantity of renal epithelium was still present. An occasional slight convulsive tendency was shown by fixed eyes or muscular movements. The lochia were scanty, but the quantity was increased by the administration of fluid extract of ergot.

On Tuesday night, she told me that she heard voices still, but that she realized they were only in imagination. For days she was troubled by wild fancies when sleeping. Tuesday night she also complained of hemiopia, which disappeared in a few days.

In health, the patient's pulse is full, strong, and sixty beats to the minute, the temperature rarely rising a fraction of a degree above normal. Until February 1st, the temperature did not fall below 99° F., and the pulse was weak, ninety beats to the minute.

January 25th, an examination of the urine gave normal specific gravity, albumen in small quantity, and careful searching revealed but one cast, though renal epithelium with pus was still largely present.

February 1st, she was allowed to sit up for the first time. On the 17th, she was able to go up and down stairs. From this time until April 14th, when she passed from my hands, she improved constantly, an examination of the urine at this date giving no albumen or casts, and very few renal epithelia with pus.

This case is reported because of the absolute freedom from premonitory symptoms, there being at no time albuminuria, œdema, headache, or nervous disturbance, and because of the profound impression on the nerve centres after but two convulsions.

Therapeutical Memorandum.

CONCERNING SOME HYPNOTICS.

BY S. G. WEBBER, M.D.,
Superintendent Adams' Nervine Asylum.

SEVERAL drugs have been lately given to the profession with the claim that they are valuable hypnotics. I have had an opportunity of testing these in the cases of many patients in the Adams' Nervine Asylum.

Paraldehyde has been some years in use. It has advantages over chloral. The immediate subsequent effects are less unpleasant. It very rarely causes headache on the next day; sometimes patients have a sensation of fullness or pressure in the head for a few hours after waking. I gave it in one case where the patient had been taking chloral in large doses, not measuring the dose, and had been injuriously affected by the drug. The paraldehyde gave, in this instance, better and more prolonged rest; the patient partially recovered his mental powers and some measure of strength. The paraldehyde was continued several weeks in nightly doses of forty minims. In this patient there was probably disseminated sclerosis, and it did not seem possible to do without some agent to produce sleep, at least so long as he was at home.

The chief objection to paraldehyde is its disagreeable odor and taste, and also the odor it imparts to the breath. I do not remember to have met any unpleasant symptoms arising from its use; but had never seen a case in which it has been used habitually for a long time. The dose is from forty five to eighty or ninety minims; sixty minims is the average dose. Occasionally a dose of eighty minims has failed to give the sleep which I have desired to obtain.

Urethan came into notice later than paraldehyde; it is much more pleasant to administer, having scarcely any taste or odor.

When I first gave it the dose was too small, but by increasing it to thirty grains good results were generally obtained. Sometimes much larger doses are necessary. It is quite soluable; fifteen grains will dissolve in a drachm of water.

The after effects are generally unimportant. It has seemed once or twice to give rise to nausea the day after; but often the patient says the sleep has been very natural and refreshing. It is not so sure to produce sleep as paraldehyde.

Hydrobromate of hyoscin has the advantage of being almost tasteless; and the dose is small. I began with a dose of one hundred and twentieth of a grain, as recommended by the articles I had read; but soon found this too small, and increased to a sixtieth of a grain, using the following formula, giving twenty minims:

℞. Hydrobromate hyoscin . . . gr. i.
Alcohol . . . . . ʒ iss.
Aquæ q. s. ut fl. . . . . ʒ xx.
M.

In a few instances I have given twenty-five minims of this mixture.

There is so little taste to this that it can be given

in some simple drink, as gruel or beef tea, without the knowledge of the patient.

In one patient it produced discomfort in the head the next day, so that after two trials it was given up and urethran given instead. In other cases the sixtieth of a grain given for a week or more has produced no bad effects. In a few cases it has failed to produce sleep, and the sleep secured in other cases has not been of so long duration as that usually produced by paraldehyde, but subsequently in these same cases the latter drug has not proved more efficacious. On the whole, my experience with this drug is that it will act favorably with a large number of patients, that it is acceptable on account of its lack of taste and odor and because of its small dose; the sleep obtained is very refreshing and natural; it is, however, rather more likely to leave unpleasant effects, and seems to lose its power by repetition sooner than either urethan or paraldehyde.

Hypnone has a strong odor of bitter almonds. One patient spoke of it as having "all the odors of Araby the blest." I have given it in capsules in dose of five to eight drops (.07 to .13) or even more, the former dose is rather small for good results. It will produce very natural sleep, and the patient awakes refreshed. It is of much less value than the drugs already considered, and fails more frequently than the others in producing sleep. It may be conveniently substituted for the others when they have been taken some time consecutively.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

CHARLES P. STRONG, M.D., SECRETARY.

Meeting June 7, 1886. Dr. Derby in the chair. Dr. E. J. Forster reported,

A CASE OF PUERPERAL DIPHTHERIA.

Dr. F. W. Johnson inquired if it was the reader's custom to order vaginal douches after delivery as routine treatment.

Dr. Forster replied that this had been his custom, but he was now making a trial of the "antiseptic pad" with a view to omitting the douche.

Dr. A. H. Nichols reported

A CASE OF POISONING BY CHLORIDE OF ZINC; WITH REMARKS.[1]

Dr. B. F. Davenport said that in reports of cases of poisoning by chloride of zinc the effects of its corrosive action were always prominent, and this was due to the ready solubility of the salt, which permitted its use in a very concentrated form. In cases of poisoning by canned fruits the majority of authorities attribute the results to lead rather than to zinc poisoning; the fermentations causing solution of the lead. This idea has usually been conclusively proven where the cases had been analyzed and the cases followed to the end.

Dr. Derby inquired if zinc chloride was commonly used in sealing cans.

Dr. Nichols said it was, because it could be used by unskilled workmen, while sealing by resin required a certain amount of practice and skill.

Dr. Greene inquired if the reader disapproved of the use of zinc chloride in any case of epithelioma of the lip, provided the use was restricted to persons of proper surgical skill.

Dr. Nichols replied that the employment of the knife was better in cancer of the lip, but that there was no reason why the salt should not be used in cancer of the breast and other parts of the body, beyond the fact that it was out of fashion and had fallen into the hands of irregular practitioners.

Dr. Forster inquired as to the effect of the amount of podophyllin which the patient might have received in this dose.

Dr. Nichols replied that he had felt sure none of the effects were due to this. There was no action produced on the intestinal tract.

Dr. Derby said that this possibility of the podophyllin playing some part in producing the final results had also occurred to him, and inquired if Dr. Nichols felt certain he could entirely eliminate this factor.

Dr. Nichols said that Dr. Johnson, who had investigated very carefully cases of poisoning arising from canned goods, had written him that the most skilled workmen had failed, in his presence, to seal cans without permitting some of the zinc chloride to enter the can, as he had proved by analyzing its contents.

Dr. H. W. Williams spoke of the advantages to be gained by combining in use cocaine and caustics, either directly or by employing hypodermic injections of the former.

Dr. Derby inquired as to the occurrence of zinc chloride poisoning among the cases of cancer treated by this agent in Paris, to which the reader had alluded in his paper.

Dr. Nichols said that these cases were very closely watched, and that he could not say the deaths were attributable to the caustics, as the fatal cases were all desperate ones, and the bad results were quite as likely from the disease. Those cases that did not do well were large cancers of the breast.

THE AMERICAN GYNÆCOLOGICAL SOCIETY.[1]

THE TREATMENT OF PROCIDENTIA UTERI BY GALVANO-CAUTERY,

by Dr. John Byrne, of Brooklyn.

In regard to the relation of laceration of the perineum to prolapse of the uterus, the speaker held that laceration of the perineum by interfering with the process of involution, may be a remote cause, but that laceration and prolapse can be associated in any other sense, cannot be admitted.

Operations on the perineum can only influence the prolapse by offering an obstacle to vulvar protrusion. Only when a portion of, or the entire cervix is removed, can we look for permanent and satisfactory results after operation on the perineum.

In February, 1872, Mrs. H., the mother of four children, presented herself with the entire womb and vesico-vaginal wall protruding. She was thirty-five years of age. The cervix was ulcerated from the

[1] See page 343 of the Journal.

[1] Concluded from page 332.

friction. She was treated by applications of glycerole of tanin and irrigation for two months. The ulceration was healed, but no impression was made on the prolapse or on the size of the uterus, which measured four and one-half inches. The cervix was then removed with the galvano-cautery loop. The patient recovered without a symptom. Five weeks later, there was no bulging of the vesico-vaginal septum, and the uterus could just be reached with the finger. No reasonable amount of force by means of a vulsellm forceps could draw it down. The patient was discharged cured and has continued well.

The whole number of cases treated with the galvano-cautery has been nine, but in three only has the cervix been removed. In six of the cases linear cauterizations were required.

Case II was a patient with procidentia who had been treated with pessaries for a long time. The cervix appeared to be healthy. A double tenaculum was introduced into the cervical canal and the whole mass pushed into the pelvic cavity and lifted to show the line of vaginal insertion. A groove sufficiently deep to admit the loop was then cut around the cervix close to the vaginal vault. The loop was then adjusted and the cervix cut through to the depth of one-fourth of an inch. The wire was then removed and tampons of glycerole of tanin inserted. Two weeks after operation, the uterus resisted all reasonable efforts to depress it. Two years after operation no perceptible change was observed. The health had never been better and menstruation was regular.

In Case III the parts were returned and the line of vaginal insertion marked in spots with the cautery knife. The entire mass was then drawn down and a deep fissure three eighths of an inch in depth made around the circumference of the cervix. Then three incisions were made in the vagina, one central and the others diverging, and the whole mass was then returned. The recovery was complete. In none of the cases has there been any peritonitis of any account.

The speaker highly recommends farther trial of the galvano-cautery in these cases.

ELECTRICITY IN GYNÆCOLOGICAL PRACTICE,

by DR. GEORGE J. ENGLEMANN, of St. Louis.

After reference to the confusion which had surrounded this subject he referred to the following points which should govern the use of electricity as a therapeutic agent. The formation of strict indications for the use of the galvanic and faradaic currents: a differentiation between the varying forms and modifications of the galvanic and faradaic current. Differentiation between the active and indifferent pole, the localization and concentration of the current, the precision of the dose, the use of stronger currents continued for a short time. He has used the galvanic or faradaic current in the reduction of the size of neoplasms, fibrous polypi, cystic growths and urethral caruncles, also in chronic pelvic inflammation and in chronic ovarian inflammation, in stenosis of the os, for the relief of the engorgement accompanying sub-involution, in prolapse when due to relaxation of the tissues. It is an aid in the correction of various forms of displacement, in metrorrhagia when due to inflammation and relaxation, in certain forms of amenorrhœa, and for the relief of many annoying reflex symptoms. In obstetrics it is useful in uterine inertia during or after labor, in cases of weak and irregular labor pains, post-partum hæmorrhage, in delayed involution, in paralysis of the urethra or bladder after labor, and in the interruption of extra-uterine pregnancy.

The only contra indication to the use of electricity is the presence of severe acute inflammation. It may be used in sub-acute inflammation. In the more acute pelvic inflammations care is required in its use.

A number of cases were then referred to, showing the beneficial effect of electricity in diminishing the size of fibroid tumors and in other conditions.

Adjourned.

THURSDAY.— MORNING SESSION.

ELECTROLYSIS IN GYNÆCOLOGICAL SURGERY,

by DR. W. H. BAKER, of Boston, Mass.

The speaker referred more particularly to the use of electrolysis in cases of fibroid tumor; he laid down the following rules for the performance of the operation: it should not be employed within a week before or after menstruation. An anæsthetic should be administered; it is better to use electolytic needles for both the positive and negative poles: the operator should be absolutely sure of the cleanliness of his needles; the needle should be deeply buried in the tumor in order that the current shall be insulated from the parts outside of the growth; the insertion of the needle should be made at the most prominent part of the growth, whether that is in the vagina or in the abdominal wall; the needles should not be too nearly approximated; if both needles are properly placed the position of the two poles makes no difference; the circuit being completed, the number of cells should be gradually increased from four to twenty or thirty; (a more exact means of determining the strength of the current would be the galvanometer, but this had not given him accurate results); the length of time during which the application is continued should be from ten to twenty minutes and should be determined by the character of the pulse. When the pulse becomes slower and weaker than normal, the number of cells should be diminished or the current discontinued. The current should be diminished gradually and the wires should be disconnected at the battery before the needles are removed. The applications should not be made at the surgeon's office. After the application the patient is to be put to bed, where she is to remain for one week.

With such precautions, the speaker had never seen shock after the operation. A single treatment is often all that is necessary. He had never found it necessary to make more than three applications, and the latter number in only one case. There should be an interval of at least from one to three months between each application.

The use of electrolysis is also of service in the treatment of inflammatory effusions. The following case was related: Mrs. X., aged twenty-eight, married, the mother of one child three years old. The present trouble had existed since the birth of the child. A diagnosis of chronic perimetritis was made. The effusion was most marked on the left side behind the uterus. For six weeks ordinary treatment was given without much benefit. For the next two months, the treatment consisted of hot water injections, applications of iodine and the use of the galvanic current, with the positive pole in the posterior cul-de-sac and the negative pole over the epigastrium, using as many

cells as possible. This was used every other day. This caused a decrease of the sensitiveness but did not diminish the size of the effusion. At the end of this time, the positive electrolytic needle was inserted into the mass and the negative sponge was pressed above the pubes. A current from eighteen cells was applied for ten minutes. At the end of a month scarcely a trace of the effusion could be felt. Before resorting to electrolytic puncture the application of the current as first employed in this case, should be tried, as it does not require an anæsthetic and avoids the slight risk which accompanies even small wounds.

The author presented the following conclusions:

(1) Electrolysis is a useful agent in the treatment of certain cases of fibroid tumors of the uterine walls and of chronic circumscribed periuterine effusion.

(2) When applied to fibroid tumors of the uterus, electric puncture is a most reasonable and efficient method.

(3) In the treatment of fibroid tumors by this agency, it is unnecessary to apply it often.

(4) Cases of perimetric effusion to be treated by this method should be selected with care in reference to the absence of all acute symptoms.

DISCUSSION.

Dr. James R. Chadwick, of Boston. Ten years ago, I tried electrolysis in one case of fibroid tumor, introducing the needle through the abdominal wall. This caused a smart attack of peritonitis. During the following year, there was no decrease in the size of the tumor. A few weeks later I was called in consultation to see a case which had an enormous pelvic abscess as the result of electrolysis. This deterred me from continuing the treatment further. I shall, however, give it another trial.

Dr. George J. Englemann, of St. Louis. The dangers mentioned by Dr. Chadwick, are those which are liable to follow puncture through the abdominal wall. By puncturing through the vagina and if possible through the tissue of the uterus we avoid the dangers of inflammation which accompany abdominal puncture. I believe that the same results can be accomplished without anæsthesia and with less danger by one electrode in the tissue and concentrating the total effect upon that electrode, by using a large electrode in connection with the other pole.

It has appeared to me that those tumors in which the muscular element predominates are less liable to be treated successfully by electricity.

Dr. James B. Hunter, of New York. My experience with this method of treatment has been limited, but I cannot say that I have seen one case of fibroid tumor permanently relieved by electrolysis. In one case in which it was freely used by Dr. Freeman and myself, I subsequently operated and removed the tumor by hysterectomy, the patient making a good recovery. I could find no evidence of the effect of the current on the tissue of the fibroid.

Dr. Matthew D. Mann, of Buffalo. I have employed this agent in one case, plunging one needle into the tumor from behind through Douglas's cul-de-sac, with a sponge electrode over the tumor on the outside. The current was kept up fifteen minutes. Six applications were employed. The size of the tumor much diminished, and the tenderness and pain were lessened. The patient is now able to attend to her duties.

PERSISTENT PAIN AFTER ABDOMINAL SECTION,

by Dr. James B. Hunter, of New York.

Abdominal section is, as a rule, performed for pain, and if this still persists, one of the objects of the operation is not accomplished. Pain before an operation may be due to various causes. It may be located in the ovaries, when it will be increased by menstruation. Disease of the tubes is a cause of pain in a large number of cases. The pain of peritonitis is of great importance. Acute peritonitis may be limited to the region of the ovaries and tubes, and the pain caused by it may be periodical in character. The presence of adhesions interfering with the mobility of the intestines and other organs is a frequent cause of pain. A severe form of pain may also be caused by displacements of the uterus.

Abdominal section is performed for the relief of pain, and the organ at fault is successfully removed and the patient recovers, but the pain continues. If there is no marked relief at the expiration of twelve to eighteen months, if the patient has been favorably situated, the operation may be pronounced a failure, so far as the patient is concerned. Such pain may be due to former peritonitis, to peritonitis following the operation, or to some defect in the abdominal wall.

Many of the cases which have been cured of diseases endangering life still suffer pain. For a number of years I have been where I could follow up these cases. Peritonitis following the operation is a cause of pain in a certain number of instances. A slight amount of peritonitis often occurs after abdominal section, and it may leave some slight adhesions, interfering with the mobility of the viscera. Inflammation in the region of the stump often causes its attachment to the abdominal wall, and thus caused pain. Sometimes the uterus is fixed by inflammation, and the distension of the bladder causes pain. Adhesions of the intestine may also cause pain. Pain may result from defective union of the abdominal incision, allowing a ventral hernia. Pain in the cicatrix may occur, as in other situations. Abscess may also develop in the wound a long time after healing has been completed.

In the way of prophylaxis, the utmost precaution should be taken to prevent the development of peritonitis. Especial care should be taken to do no violence to the intestines. Antiseptic precautions should be adopted. The stump should be tied with aseptic silk. The early and judicious use of drainage and irrigation will go far toward preventing inflammation. The cold coil, with antipyrine, should be resorted to if there are any indications of peritonitis.

In the treatment of the pain, blisters, vaginal injections, and the use of iodine may be resorted to. The internal use of opium is usually demanded. Such treatment can, however, scarcely be expected to cure the pain. Rest in the horizontal position is, perhaps, better than any medicine. If all palliative measures have been tried, and at the end of twelve or eighteen months there is no improvement, a second operation may be warranted. The dangers of operative procedure, and the uncertainty of the operation causing any improvement must be stated to the patient. If the patient prefers the operation, an exploratory incision should be made. In one case the speaker had found a loop of intestine attached to the uterus, which he loosened, with a good result. In another case, considerable relief was afforded. As a rule, however, it is

not possible to separate adhesions, and, if separated, they are prone to unite, and fresh peritonitis is apt to follow. Often the exploratory incision is all that can be made.

CONCLUSIONS.

(1) All cases of abdominal section done for the relief of pain should be carefully followed up for at least two years, and not counted as cured simply because the operation has not been fatal.

(2) Peritonitis following operation is to be dreaded as much for its remote consequences as for its immediate danger.

(3) Extreme caution is demanded when the operation is undertaken where there exist the physical signs of chronic peritonitis.

(4) Secondary operations, as a rule, are of no value, although occasionally they may afford relief.

(5) Where the operation is done for the relief of pain, a guarded prognosis should be given. There are certain chances that a perfect cure will not result, even if the operation itself is entirely successful.

DISCUSSION.

Dr. A. J. C. Skene, of Brooklyn. Among the causes of pain after laparotomy, I would place the ligature. In tying the pedicle after removal of the ovaries, some traction must be made upon the broad ligament, and the nerves must be drawn upon. That form of pain may disappear. Another cause of pain is the application of the ligature just tight enough to arrest hæmorrhage, without destroying the nerves. I think that we have more pain after the use of the ligature than after the use of the cautery clamp. The cautery, as a means of treating the pedicle, has never been thoroughly tried in this country.

In regard to what constitutes success after abdominal section, I would say that many of the cases which I have reported as failures have subsequently turned out to be most successful.

Dr. R. Stansbury Sutton, of Pittsburg. Dr. Hunter has, in his paper, alluded to a case on which I operated two and one-half years previously. In this case the ovary was surrounded by a coil of intestine, which had undergone fatty degeneration to such an extent, that its own weight was sufficient to cause it to break. I removed the ovary with the diseased bowel, and brought the edges of the intestine together. The woman recovered, but she was not cured of her pain. It is not often that we have the opportunity during life to determine the results of a resection of the intestine. I should like Dr. Hunter to tell us what he found.

Dr. W. Gil Wylie, of New York. The author appears to have completely ignored the general condition of the patient. What will cause pain in one person will not in another. With reference to peritonitis, I would say that I regard it as a condition behind which there is some disease. In chronic peritonitis, there is often some cause which keeps renewing the inflammation. In many of the cases that suffer after operation, the pain is due to imperfect operation. Sometimes a small portion of diseased tissue is left. I have taken the precaution to destroy the diseased tissue that may be left beyond the ligature, either by carbolic acid, or preferably by Paquelin's cautery. This has lessened the mild attacks of peritonitis. Sometimes the inflammation is centred around a ligature, leading to abscess and the formation of a sinus. In some of these cases the trouble can be cured by dilating the sinus and fishing out the ligature. In many cases the peritonitis is due to the bursting of a small cyst. I have intentionally burst these cysts on the table, put the patient to bed, and watched the case.

Again, in cases where there is chronic inflammation of the lining membrane of the uterus, this is not always cured by removal of the tubes and ovaries. This may cause pain not only in the uterus, but reflexly in other parts of the body. These pains can often be cured by dilating the uterus and applying carbolic acid.

Dr. Robert Battey, of Georgia. I have had some little experience with the difficulties alluded to by Dr. Hunter. We are all familiar with the neurotic women. As a result of a carious tooth, an intense neuralgia may be set up, which may continue for years, and not be relieved by the removal of the diseased tooth. This is probably due to an alteration in the nerve-tissue itself. The explanation that these pains persisting after abdominal section were due to inflammation and adhesions has been carefully considered by myself, but I have wholly failed to find a satisfactory explanation in this quarter. The neurotic cases which have given me the most trouble have been almost uniformly those where I was unable to find any such deposit in the pelvis.

The speaker has said that at the end of twelve or eighteen months, we should give up these cases as failures: I should qualify that statement by more than doubling the limit. Some of the cases which were most unsatisfactory at the end of a year have achieved the most gratifying cure by the lapse of time.

Among the causes which produce this neurotic condition, I am inclined to rank in the first place, an acquired neurotic habit from long suffering. In looking for causes, I have been much struck by one point, that alluded to by Dr. Skene, that is, the use of the ligature and especially a rather loosely tied ligature. Dr. Skene suggests the use of the cautery and clamp. I formerly used a method which has not been alluded to, and that is the separation of the ovary from its attachment by the ecraseur. In these cases, I did not have any of these troublesome neuroses and there was no hæmorrhage. I have seriously been considering a return to this method of treatment.

With regard to treatment by a second opening of the abdomen, I would call attention to the fact that by a simple opening of the abdomen, purely for diagnostic purposes, unaccompanied by any great disturbance of the parts, the condition of the patient is often greatly improved, especially as regards pain. In a case of gonorrhœal inflammation, I opened the abdomen after the failure of all other methods of treatment, finding everything glued down by adhesions. I abstained carefully from all manipulation after satisfying myself of the entire impracticability of any operation. The patient, without any deception on my part, gained the impression that the ovaries and tubes had been removed. She has now been under observation two months and the relief has continued. Before the operation she used full doses of morphia, but since then she has used no anodyne whatever. She has not menstruated since the operation.

I think that after removal of the ovaries and tubes, the uterine trouble will get well, but the cure may be

hastened by applications to the interior of the uterus, of a solution of iodine in carbolic acid.

Dr. H. P. C. Wilson, of Baltimore. I am satisfied that while cases do occur where the pain after laparotomy continues as a result of local adhesions, yet the majority of cases belong to the class of cases described by Dr. Battey, where the condition is due more to the neurotic element than to the operation. Most of these are long-standing cases, where the mental condition has become so morbid that the patient is almost insane on the subject of her ovaries and tubes. Even if these organs are removed, the neurotic condition may remain for a long time. Where the woman has to work and has not time to think of herself, these pains more rapidly disappear than where she is pampered with every luxury. Nothing is so good for the relief of these pains than exercise by walking. There is one remedy of which I use more than any other drug in the materia medica, that is assafœtida. I never order less than sixty pills. This tends to keep the mind occupied, and these conditions are more mental than physical. A friend tells me that in one such case, he obtained great improvement by ordering the patient to eat a reed-bird every two hours, day and night.

Dr. Matthew D. Mann, of Buffalo. I suppose that Dr. Skene, in speaking of the ligature, refers to silk. I cannot see that the objection would hold against cat-gut. I have used this in a number of cases and have had no trouble with it. As regards the time after operation at which recovery may occur, I have seen it take place long afterwards.

Dr. James B. Hunter, of New York. Dr. Sutton has asked me what I found in the case on which he had operated. The patient was suffering much pain, which was increased on defecation. I opened the abdomen a little to the right of the original incision and found the attached portion of the gut. A white, oblique line showed where the two portions of the gut had united, and this was fastened to the abdominal wall. It showed a very satisfactory result. I removed the other ovary and tube and found them perfectly healthy. The condition was neither improved nor made worse by the operation.

The neurotic condition has been referred to, but I think this is secondary. As regards chronic neuritis. I agree with Dr. Battey that usually after removal of the ovaries nothing more is required.

I am willing to admit that my limit was too short, and should be extended to two or three years. I think that it is not well to expect any improvement after removal of the ovaries and tubes for at least twelve months. I think that it takes that long for the system to become accustomed to the changed condition.

THE BLUE DISCOLORATION OF THE VAGINAL ENTRANCE AS A DIAGNOSTIC SIGN OF PREGNANCY,

by Dr. James R. Chadwick, of Boston.

The speaker had made it a point in all cases of early pregnancy to make a note of how much discoloration he could detect; he had tables of four hundred and forty cases examined. He had divided the discolorations into four groups: First, doubtful, where it was so faint that he could not be certain of its presence; Second, suggestive, where it was more marked; Third, characteristic, where the discoloration, though faint, is confined to the anterior wall of the vagina and more particularly to the urethra, just below the meatus and on either side of the meatus. In every instance where this was present the woman was pregnant, with one exception; and Fourth, marked, where the congestion has become deep and exhibits the appearance constantly seen during pregnancy.

He did not claim that the characteristic discoloration is seen in every case, but if carefully looked for, it would be found quite pronounced in the majority of cases. The color varies from a violet to a dark, dusky, almost black color. He claimed that this sign was of especial value in cases of retroversion where the size of the uterus could not be determined and in extra-uterine pregnancy. He had obtained much assistance from it in a few cases of pregnancy accompanied by fibroid tumors, and also where there was a large accumulation of abdominal fat. When present, this sign is of decided value in the early months of pregnancy, but its absence should not be accepted as a positive proof against pregnancy. Cases were cited in which the discoloration had been observed in the seventh or eighth week of pregnancy.

DISCUSSION.

Dr. H. P. C. Wilson, of Baltimore. I consider this one of the most valuable means of diagnosticating pregnancy in the early stages. It is invaluable in cases where women wish to deceive you.

Dr. A. J. C. Skene, of Brooklyn. This has seemed to me to be a most reliable sign in the early months of pregnancy. I believe that it is an illustration of the physiological hyperæmia of the formative stage of development.

Dr. Joseph Taber Johnson, of Washington. Some years ago I referred to this point, and the discussion which followed seemed to indicate that the discoloration was a congestion produced by interference with the return of the venous circulation by the pressure of the enlarged uterus. It was held that the same discoloration could be produced by any other tumor which would have the same effect as the pregnant uterus.

Dr. William H. Parrish, of Philadelphia. In regard to the continuance of the discoloration after labor, I have noted that in primiparæ where involution of the vagina takes place completely, the discoloration disappears with corresponding rapidity. Where there is sub-involution, the blueness may continue for a longer time. In multiparous women where the blueness was marked, I have associated it with a condition of sub-involution of the vagina.

Dr. James R. Chadwick, of Boston. I have failed to notice any persistence in the discoloration described. The general discoloration may persist, but this characteristic blueness will, I think, be found to disappear. I have looked for this sign in forty or fifty cases of fibroid tumor, and have not found it in a single instance.

AFTERNOON SESSION.

Dr. R. Stansbury Sutton, of Pittsburgh, exhibited the specimens from three cases of

SUPRA-VAGINAL HYSTERECTOMY,

and made some general remarks on the operation.

DISCUSSION.

Dr. W. Gil Wylie, of New York. I think that in the large number of cases all that is necessary can be done by the vagina. In many cases of fibroid tumor, however, where hysterectomy has been performed for

hæmorrhage, I think that curetting the cavity of the uterus would have obviated the necessity for the operation. Fibroid tumors cause hæmorrhage by enlarging the uterine cavity. Where there is hæmorrhage, there are nearly always granulations. With the curette, not only may the hæmorrhage be brought to a normal standard, but I have seen the tumor diminish in size. It has appeared to me that fibroid tumors have a period of development and a period of decay. After a fibroid tumor has continued five or eight years its vitality is lessened, and it may diminish in size. This is not the case in all instances, and we meet with cases in which, if hysterectomy is not performed, the patient will die, as the result of the hæmorrhage.

The President, DR. THADDEUS REAMY, of Chicago. I think that if Dr. Wylie uses the curette in cases of fibroid tumor, he must, notwithstanding the adoption of all antiseptic precautions, have a certain number of cases of septicæmia. Curetting is much more likely to be followed by septicæmia when there is a fibroid tumor of the uterus than when the operation is done for ordinary fungous granulations. I believe that curetting under such circumstances would be almost as dangerous as the removal of the tumor.

DR. W. GIL WYLIE, of New York. So far as my own experience goes, I have had no trouble whatever. I invariably use antiseptics before the operation, and douche out the cavity afterwards.

THE HIGH MORTALITY OF THE RECENT CÆSAREAN OPERATIONS IN THE UNITED STATES, WITH THE REPORT OF A CASE,

by WILLIAM H. PARRISH, M.D., of Philadelphia.

S. M., married, was admitted to the Philadelphia Hospital, while in labor, September 20, 1885. She was the mother of two children, the last of which was born twelve years previously. Labor had begun on September 18th, the membranes soon rupturing. She was seen by two physicians, who had her sent to the hospital. The cord had prolapsed, and the pulsations had ceased before she was sent to the hospital. On admission, she was found much exhausted, with the cord protruding from the vagina. The resident physician not recognizing the gravity of the case, Dr. Parrish was not summoned until some hours after her admission. At this time the uterus was in a state of tonic spasm; the patient was etherized. The vaginal examination revealed merely a rigid condition of the cervix; the pelvic canal was roomy. The hand was introduced into the vagina, and two fingers into the uterus. The examination showed two hard, intramural fibroid tumors about the internal os. The author concluded that Cæsarean section should be performed without delay, and three of his colleagues were sent for in consultation. They all agreed that attempts at enucleation should not be made, but they did not agree as to the necessity of Cæsarean section. They were in favor of craniotomy. The skull was perforated, but it was found impossible to grasp and crush the head. Various instruments were tried without avail. The necessity for Cæsarean section was then conceded by all. The uterus had then been emptied of its waters for at least forty hours.

The vagina and lower part of the uterus were washed out with a solution of corrosive sublimate. The cervix was closed by tying around it a rubber drainage-tube. The abdomen was opened and the section of the uterus made. At once a very offensive gas escaped. A large child was removed. The placenta was not in the line of the incision. Antiseptic precautions were employed during the operation. Deep and superficial sutures were introduced into the uterus and the abdominal incision closed. A hypodermic injection of ergotin was at once administered. After the operation the tube around the neck was removed. The patient died twelve hours later from exhaustion and rapidly developing septicæmia.

At the autopsy, the lips of the uterine incision were found in contact. Three dense intra-mural fibroid tumors were found.

DR. PARRISH then referred to the great mortality of this operation in the United States, and presented the statistics of Dr. Robert P. Harris, of Philadelphia, of which the following is a synopsis:

Cæsarean Operations in the United States	144
Women saved, 37.5 per cent.	54
Children living when delivered,	64
First fifty operations, saved, 34 per cent.	
Second fifty operations, saved, 24 per cent.	

Operations performed in good season when the condition of the woman was favorable have in this country saved seventy-five per cent. of the women and eighty per cent. of the children.

Cæsarean section has been performed in thirteen cases where the obstruction was due to fibroid tumors and of this number four recovered and five children were living. The time in labor in the saved cases was nine and one-half hours, fourteen hours, three days, and four days.

The following rules were then given for the performance of the operation.

(1) Carefully determine the degree of obstruction and operate early in labor, as soon as the os is sufficiently dilated to permit drainage, and before the rupture of the membranes.

(2) Operate with full antiseptic precautions, but the spray over the abdomen is unnecessary.

(3) Control hæmorrhage by compression, either with a rubber tube or manually, preferably by the latter means.

(4) Introduce numerous deep and superficial sutures so as to approximate accurately the muscular walls of the uterus, but do not carry the sutures into the endometrium. Removal of a section of the muscular wall is unnecessary.

(5) Protect the peritoneum from the discharges and if it become soiled, it should be carefully cleansed.

(6) Ergotin should be administered at the beginning of the operation.

The PRESIDENT. In three thousand cases of labor I have never made a Cæsarean section nor any of its modifications. It is only now that the people are coming to recognize that craniotomy is not to be performed in any but the rarest instances, and that the sacrifice of life is unjustifiable. The explanation of the better results in other countries is not so much in the skill of the operators as in the condition of the cases when operated upon.

DR. WILLIAM H. PARRISH, of Philadelphia. I agree with the president that craniotomy should be an operation of exceeding rarity. The people are not yet ready in this country to accept Cæsarean section, but one of the great troubles is with the general medical profession who regard this as an operation almost necessarily fatal.

CLINICIAN *VERSUS* PATIENT.

THE very general and extended use which the present methods of medical instruction make of the clinical material afforded by hospitals and dispensaries has no doubt raised the question in the minds of the lay governors and supporters of these eleemosynary institutions as to whether their beneficiaries are likely to suffer any detriment through their employment in the education of students.

We believe that in this country at least the safeguards which not only public sentiment but professional care throws about the occupants of hospital wards are amply sufficient in the great majority of cases to prevent science from usurping anything that properly belongs to the rights of the individual; though doubtless cases have occurred in which the too zealous devotees of science have forgotten that their patients had a right above everything else to be put in the speediest way of getting well, which for some reason or other seems to be the leading desire in the minds of many sick people.

There has been, however, some loose talk about the subjection of hospital patients to experiments by those who do not sufficiently appreciate the fact that medicine is, at least in its present stage of development, an experimental science. Most of the experimentation to which the hospital patient is subjected, is common alike to him and to those who enjoy the services of the physician in his private practice. The earlier cases which are subjected to any new operation or medicinal treatment, are placed at a certain disadvantage, and this holds true whether the procedure be new to general medical knowledge or only to the experience of the individual practitioner.

The woman who is relieved of an ovarian tumor to-day, by an operator who is completing his series of a hundred successful cases is placed by fortune in a vastly more favored condition than she who first risked the operation under the knife of McDowell. But the immunity of the former was gained through the peril of the latter.

So there is always an experimentation which is proper in medical practice, and whose good fruits are gathered by all future patients within hospitals or without. Such experimentation is not confined to the hospital and if its results are more widely seen in such institutions, it is merely because of the better facilities there granted for collecting and collating observations.

One chapter of the Boylston Medical Prize Essay for the current year[1] is devoted to a consideration of the possible conflict between the interests of medical science and those of the individual patient and certain indefeasible rights of the latter. Among these are enumerated exemption from over-frequent physical examinations and from instrumentation for the mere purpose of giving instruction in diagnosis; the protection of female patients from exposure; the maintenance of every safeguard to parturient women against the transference of septic infection in connection with "touch courses," and the exclusion of labor cases from the wards of general hospitals; the subjection of the privilege of making an autopsy to the expressed consent in each case of the patient or his friends; and finally, the exemption of patients from experimentation merely *as such*.

On this last subject an English contemporary in discussing the essay in question, points out the difficulty of discriminating in some cases between what is legitimate and what is illegitimate in the matter of experimentation. The essay admits this difficulty and states that it is impossible to draw a definite line. There are certain classes, however, into which these cases seem to divide themselves. For instance, some investigations of interest to the student of anthropometry or of other statistics, to the physiologist or to the electrobiologist, can be made without causing pain or any other harm to the subjects. To ask permission to make them would be a waste of breath and to take it without asking, if theoretically a usurpation, practically violates no rights. Then there is the use of new remedies whose physiological action has been more or less investigated and with the result of indicating a probable or possible applicability to the cases in hand. Again, there is the debatable ground already referred to of tentative operations, which the physician would not care to have performed upon a member of his own family, but which, nevertheless, may give the best chance of present help to the patient, as well as of guidance for future cases.

Finally, there is the class of studies in which pain and nervous distress (whether real or imaginary) are caused through experiments that are utterly foreign to the needs of the patients who happen to be made their subjects. As an example of such usurpation the author of the essay referred to, has cited the wholesale experiments with nitrite of sodium, carried on by two eminent English therapeutists not long since, where the drug was administered to many different patients and repeatedly to the same person, and where effects alarming at least to the subject were frequently

[1] The Relation of Hospitals to Medical Education. Boston: Cupples, Upham & Co. 1886.

produced. Without expressing any opinion as to the appropriateness of this citation as a case illustrating the usurpation of the rights of patients, we may say in general that there seems to be a fairly definite distinction between an investigation which is carried on upon an entire ward of patients at the expense of their greater or less physical detriment, for the sake of determiping what are the vaso-motor or other phenomena produced by a given drug, and the trial for primarily therapeutic ends of a remedy which has already given evidence of some adaptation to the case in hand.

The hospital is a proper place for studying the therapeutic action of drugs, but their purely physiological and their toxic properties should be elucidated elsewhere. The subjects for such an experiment should offer themselves voluntarily and not be taken *nolens volens*.

That such discussions as the foregoing with regard to the right of the patient are not absolutely uncalled for, is shown by a case which has recently excited some attention among medical circles in Europe. In the Hospital of St. John, in Brussels, during an examination of candidates in surgery, one of the central examination jury removed an antiseptic dressing which had been personally applied with unusual care by the visiting surgeon in a case of operation upon a suppurating knee-joint. When the latter surgeon visited his patient the next day he found him very much worse, and soon after amputation of the leg became necessary as the only means of saving his life.

Very naturally the surgeon reported the circumstances to the "*Conseil des Hospices*," the Board of Management of the hospital, and very properly that body adopted a rule that hereafter one of the medical officers in charge of the ward should be present on every occasion when a clinical examination was to be made, to inform the examiners what patients might without injury to themselves be made use of for examination purposes. The jury of examination, however, felt themselves so much aggrieved at the proposition to establish a surveillance over their proceedings that they refused to conduct any more examinations at any of the hospitals under the control of the *Conseil des Hospices*, and have transferred all their examinations to an institution which is under a different supervision and where the jury, as it says, is "treated with the consideration that is due to it."

This unfortunate affair, which has led to a good deal of ill-feeling in the medical and even the non-professional circles of Brussels, all arose, it is likely, from a misapprehension by the examiner of the nature of the case which he assigned for the candidate's examination, but it emphasizes none the less the fact that the interests of clinical instruction may be pushed to a point where they come in conflict with the safety of the patient.

— The New York Board of Health has ordered a rigid inspection of all Chicago meat received.

CYSTS OF THE TESTICLE AND EPIDIDYMIS.

THE above subject has been studied by Hochenegg[1] from a large number of testicles (332) that have been removed during life or after death.

The cysts seem to divide themselves into two groups, the one composed of those standing in connection with the seminal ducts (spermatic cysts, spermatoceles) and the other, by far the more frequent, having no such relation.

Among the spermatoceles are distinguished those which are within the tunica vaginalis and those without. The causes which tend to their production are either congenital or acquired. Among the first is a failure on the part of the vasa efferentia to unite with the rete testis. Such an aberrant branch can be dilated by the pressure of the secretion during function. They are usually found situated either between the testicle and epididymis or in the head of the latter.

Some parts of the conducting apparatus would seem to be especially predisposed to dilatation from their anatomical structure and situation. The lumen of the seminal canals is narrowed in the rete, is enlarged in the vasa efferentia, and again diminished in the duct of the epididymis. The parts lying directly before these contractions would naturally be the most liable to be affected. Thus cysts would be expected from the canals of the testicle and epididymis. But in point of fact they occur only rarely in the former situation, so that another factor than the capability of resistence of the wall must come into play, and that is found in the condition of the surrounding connective tissue.

The sessile hydatids of Morgagni and the vas aberrans of Haller which often communicate with the epididymis and therefore normally contain spermatozoa are at times found to be dilated. But for the formation of a cyst there, it is necessary to have an impulse, which stops the stream of the secretion in one or the other of the efferent ducts. Two cases are recorded where violence was assigned, resulting in the tearing of the testicle from sudden bending and stretching. The ends of the lacerated tubules were closed and then gradual dilatation followed.

Epididymitis can lead to a distention of the canal but not to a cyst, as the tube is not obliterated entirely, In one case an adhesion had taken place between the testicle, epididymis and tunica parietalis in consequence of an abscess. This was evidently a cause for a sharp bend in the vasa efferentia at their point of passage through the head of the epididymis, and subsequent enlargement. Further causes are to be found in retention of secretion. About every fifth man is the possessor of a spermatocele.

The spermatocele that lies without the tunic vaginalis is the most frequent, and arises from the dilatation of the efferent canals which lie in the serous duplicature between testicle and epididymis and in the loose connective tissue. Generally this is filled by the direct pressure from the gland but at times by the indi-

[1] Med. Jahrb. d. k. k. Geselsch d. Aetzte in Wien, 1885, 1 Heft.

rect from its adjunct. In many cases a preëxisting rupture of one or more canals is not to be excluded. The semen which has extravasated is encapsulated, so that a sacculated cavity is formed communicating with a duct, by which it is gradually dilated.

The further distention occurs at the expense of the common tunic in the inguinal canal, just as large hydroceles involve the skin of the penis for their covering. The wall of the cyst is composed of an external connective tissue coat and an internal epithelial layer, which is composed in young cysts of stratified columnar cells, with here and there ciliated ones, while the older ones are covered with several layers of flattened cells.

The spermatocele within the tunica vaginalis is the rarer form. It is formed by a cyst which has developed from one of the sessile hydatids of Morgagni or from the ducts of the epididymis projecting into the cavum vaginale, and is covered by the visceral layer of the tunica vaginalis. The cause of these is to be sought in trauma, abnormal formation, or inflammation.

Large spermatoceles have the form of an inverted pear, small intra-vaginal and all extra-vaginal ones have no characteristic shape. The testicle is found at the lower end of the tumor, and is placed horizontally in the extra-vaginal forms.

To the cysts which do not belong to the seminal ducts belong those in the epididymis, the testicle and beneath the peritoneal layer of the tunica vaginalis. These are (1) subserous cysts (of unknown origin); (2) Cysts from dilated lymph vessels; (3) Cysts from subserous or subalbugineous extravasations.

COMBINED SCLEROSIS.

Grasset[1] has recently given an elaborate *résumé* of the subject of combined sclerosis, having collected the reports of thirty-three cases, including three cases from his own observation. He considers that the ætiology is the same as that of simple posterior spinal sclerosis, and that there is no definite heredity — unlike Friedreich's ataxia, which is also a combined sclerosis — except a general neuropathic taint. The symptoms in his own cases were a combination of the symptoms of spastic paralysis and tabes dorsalis, spasm and rigidity of the limbs, with contractions, being added to the classical symptoms of tabes, or else anæsthesia, lightning pains, and other tabetic symptoms being added to a spastic paralysis. A careful analysis of the thirty-three cases showed, at least, some symptoms of tabes in every case, while every case but one showed also some muscular symptoms. The condition of the patellar reflex was of interest. In fourteen cases no data were given, in twelve cases it was abolished, in seven it was somewhat exaggerated. In two cases it was exaggerated at first, but later it was abolished, having, as he thinks, the advance of the disease in the posterior columns.

He believes that the contractions are due to a lesion of the lateral columns. He thinks that the symptoms demand a lesion of both columns, which is confirmed by the autopsies. The lesion is a mixed one; in the posterior columns it is strictly systemic, while in the lateral columns it is diffuse. This is not exceptional, however, for in general paralysis we may get a diffuse lesion in the brain, and a systemic lesion in the cord. He, therefore, considers combined sclerosis as a clinically distinct affection. He quotes Zacher and Westphal as saying that, in a combined lesion, spastic symptoms do not develop in the limbs when the lesion of the posterior columns has reached the posterior root-zones in the corresponding section of the cord. Tabes dorsalis may be eliminated by the presence of spastic symptoms, spasmodic tabes by the presence of ataxic symptoms. All these forms of tabes, however, involve the whole cerebro-spinal system. If the patellar reflex is present in ataxia, it points to combined tabes. The combined form has ataxic symptoms (pains, anæsthesia, incoördination), combined with spastic symptoms (paralyses, contractions, and spasms), and cephalic and meso-cephalic (cough, dyspnœa, etc.) symptoms. Anatomically, there is a chronic myelitis in the posterior and lateral columns, neither wholly systemic nor wholly diffuse, but systemic in the posterior columns, and diffuse in the lateral — a mixed myelitis.

Strümpell[2] reports a case of apparently uncomplicated spastic paralysis, where the autopsy showed not only sclerosis of the lateral pyramidal tract, but also of the lateral cerebellar tract and the columns of Goll, with a certain amount of sclerosis of the outer circumference of the cord. All the symptoms could be referred to the disease of the lateral tract. As there was no paralysis, but a marked increase in the reflexes, the theory is advanced that the reflex inhibitory influences reach the motor-cells by a different path than the motor influences. He considers that this case, and others similar which he has reported, form a definite type of combined systemic disease of the cord. The pyramidal tract seems to be affected first and most, next the cerebellar tract, and lastly, the columns of Goll.

The sclerosis of the pyramidal tract begins exceptionally in the lower lumbar cord, is well marked in the lumbar enlargement and the dorsal cord, and ceases at the decussation of the pyramids. The sclerosis of the other systems of fibres is most marked above. The primary degeneration of the lateral tract, then, is ascending, and that of the cerebellar tract and the columns of Goll is descending — exactly the opposite of secondary degeneration. Vierordt[3] also finds the primary degeneration of the columns of Goll ascending. The degeneration of the cerebellar tract seemed to cause no symptoms. There was no loss of

[1] Grasset. Du tabes combiné (ataxo-spasmodique), ou sclérose postéro-laterale de la moelle. Contribution à l'etude clinique des myélities mixtes.) Archives de Neurologie, March, May, July, 1886.

[3] O. Vierordt. Degeneration der Goll'schen Stränge bei einem Potator. Archiv. für Psychiatrie, XVII, 2, p. 365, 1886.

sensibility worth mentioning, but in one case some vesical disturbance might be attributed to the disease of the columns of Goll.

In all cases of apparent spastic paralysis, we must bear in mind this form of combined sclerosis, although transverse myelitis, multiple sclerosis, etc., may cause similar symptoms. He differs entirely from Grasset in assuming a mixed form as a combined sclerosis, where the symptoms of spastic paralysis and tabes dorsalis are combined; but he divides his combined systemic disease into three classes: Friedreich's ataxia, tabes dorsalis, and the spastic form, to which probably the cases once classed as "pure lateral sclerosis" belong.

Westphal [4] reports two cases of disease of the posterior columns, with retained patellar reflex. In both cases motor weakness and some muscular rigidity on passive motion were added to symptoms of tabes, and the patellar reflex was retained until a short time before death. The autopsies showed not only disease of the columns of Goll and Burdach, but also degeneration of the lateral cerebellar, and lateral pyramidal tracts, and of the anterior columns, especially the columns of Türck. On comparing these cases with others, Westphal finds that there is a region in the posterior root-zone external to a line drawn from the projecting angle of the posterior cornu, parallel with the posterior fissure.

If this region remains healthy in the junction of the dorsal and lumbar cords, the patellar reflex will persist, but as soon as it is invaded, the reflex disappears, and the more change there is present, the longer time before death did the reflex vanish. The disease of the posterior columns elsewhere accounts for the pain, anæsthesia, ataxia, etc., etc.; the disease of the lateral columns for the motor weakness and paralysis. Combined sclerosis does not develop from a previous myelitis, for the meninges showed only secondary changes. He denies utterly Strümpell's [5] claim that paraplegia developing in tabes dorsalis points to a systemic affection of the lateral columns, for, although they may be affected, it has not the remotest resemblance to a systemic disease. In fact, he considers the theory of the existence of special "systems" of fibres very uncertain. The clinical picture is that of tabes.

MEDICAL NOTES.

— Dr. Jacob L. Williams, of No. 1 Mt. Vernon Street, Boston, writes us: "I have seen two cases of fingertips, severed by careless use of a 'hatchet,' unite, and become practically as good as ever."

— Considerable comment of an adverse character has been caused in the medical journals of this country by the reported exhibition at a recent meeting of the American Microscopical Society in Chatauqua, before a mixed audience of men, women, and children, of the "germs of life" consisting of living human spermatozoa.

— At a *conversazione* given last week at the Toronto School of Medicine, as we learn from a local journal, dancing took place in the dissecting room, which was gaily festooned with bunting, and the uniforms of military officers, together with the ladies' evening toilettes, banished any grim suggestions of the place.

— A man went into a beer-shop in Berlin, and poisoned himself there. The landlord despatched his daughter for a doctor, who did what he could for the man and sent him to the hospital. When he recovered he refused to pay the doctor, on the ground that he had not desired his services. The police, too, declined to settle the account, as also did the landlord, though it amounted only to the modest sum of a dollar. The Berlin Medical Defence Society then took the matter up and sued the landlord, who, in turn, was defended by the Publicans' Society, and the matter has now been in litigation for more than four years, with the result that the doctor, instead of getting his dollar, has had to pay the costs, amounting to about twelve dollars. The only mitigating circumstance to the doctor would seem to be that legal expenses have not been proportionally heavier than the fees for medical attendance.

— The *Sanitary Engineer* points out a possible danger in the water-supply of those southern cities that have been affected by the earthquake, which it may be well to bear in mind, and that is, that some of the water-pipes may have been displaced or cracked by the earth tremors. At some points these water-pipes pass through sewers, in which case, if broken and empty of water, a risk is incurred that would not exist if they were under pressure, and while there is little probability that there will be any dangerous leakage, its possibility should be recognized and guarded against. There is also some risk from injury to sewers, and from loosening of badly made joints in house-plumbing. A thorough house-to-house inspection from the sanitary point of view is a highly desirable thing for Charleston, and should be carried out within the next three or four months. All these things are, however, no doubt well understood by the sanitary authorities and physicians of Charleston, and will be attended to in due time.

BOSTON.

— The Board of Health of Boston, discovered last week a severe case of small-pox at the West End, and removed the patient to the Canterbury Street Hospital.

— Mr. William Cavanaugh, of Washington Village, has brought suit against the individual members of the Boston Board of Health, Messrs. Durgin, Babbitt, and Keith, and attached the property of each to the amount of $10,000, for damages to his property, caused by the erection of a dam there about four years ago, for the purpose of flooding the immediate territory, which was in a bad condition. The estate of ex-City Engineer Wightman, deceased, has also been attached for $10,000. Cavanaugh sued the city some time ago, but

the city solicitor had the case non-suited, pleading lack of responsibility. Cavanaugh now claims that the members of the Board and the ex-City Engineer were responsible.

NEW YORK.

A female patient recently died in a dentist's office in Brooklyn, E. D., while taking ether for the extraction of a tooth. A number of physicians labored unsuccessfully to resuscitate her, but the result of the autopsy made by the coroner has not been made known.

— The Brooklyn Board of Supervisors have followed out the recommendation of the Grand Jury, and made arrangements for the relief of the insane at the Flatbush Asylum. At a meeting of the Board held October 7th, Supervisor Pigott offered a resolution, which was adopted, that five temporary buildings, proposed by the Charities Commissioners, and so constructed as to meet the approval of the physicians of the Asylum and of State Commissioner Ripley Ropes, be erected at once on the county farm at St. Johnsland, L. I. The Supervisors were to meet again on the 10th, and award the contracts for these temporary structures: so that within a month and a half two hundred and fifty of the Flatbush patients can be removed to these new quarters.

— Dr. James Anderson, one of the most venerable and highly esteemed practitioners of the city, died October 7th. Although in his eighty-ninth year he enjoyed remarkably good health and was in his usual vigor until October 4th, when he was attacked with cholera morbus, the exhaustion from which proved fatal. He was born at the Battery at the lower end of New York, February 21st, 1798, and was descended from an old Dutch family. He began the study of medicine under the celebrated Dr. David Hosack, and in 1821 was graduated from the College of Physicians and Surgeons. After graduation he was associated in practice with his preceptor for a number of years, and during this period devoted much time to the quizzing of Dr. Hosach's numerous students. He was one of the early presidents of the New York Academy of Medicine, and was at one time President of the State Medical Society. He was also the founder and first President of the New York Physician's Mutual Aid Society.

— William Henry Dudley, President of the Collegiate Department of the Long Island College Hospital, died at his home in Brooklyn, on the 8th of October. The immediate cause of his death was pulmonary hæmorrhage occurring during an attack of bronchopneumonia; although his constitution was undermined by diabetes, from which he had been suffering for over two years. Dr. Dudley was born in Ireland in 1811, and was graduated from the Royal College of Physicians and Surgeons in Dublin, in 1833. Removing to the West Indies, he was made Health Officer at Port Maria, Jamaica, and was also elected a Fellow of King's College there. In 1841, Dr. Dudley came to New York and received a diploma from the College of Physicians and Surgeons in this city. He soon removed to Brooklyn, however, where his life-work has been the building up of the Long Island College Hospital. He was instrumental in its organization in 1859, contributing liberally of his private means and time to make it a success; and this is said to have been the first adoption in this country of the plan, since so generally in vogue, of connecting a hospital directly with a medical college for the purposes of clinical instruction. Dr. Dudley was, besides, one of the physicians of St. John's Hospital, and had a large private practice in Brooklyn, where he was greatly beloved for his many genial qualities. He was twice married, his first wife being Miss Emily M. Fitz Gibbons, of Jamaica, West Indies, and his second, Miss Charlotte G. Duckintz, of Brooklyn, and two sons and a daughter survive him.

Miscellany.

OBITUARY.—JOSEPH SAMPSON GAMGEE, F.R.S. Ed.

This well-known English surgeon died September 18, at his residence in Birmingham, at the age of fifty-eight. Five years ago Mr. Gamgee was laid by for some weeks with a serious attack of hæmaturia, which evidently left its mark upon his kidneys and his general health. He regained, however, a fair amount of strength, and was enabled to follow his ordinary avocations. Three weeks ago, before his death, while walking quickly along the street at Dartmouth he fell, injuring his hip. Though suffering acute pain, he was unwilling to admit that there was any grave damage, and though for the most part confined to his bed, he saw his patients and dictated his correspondence. After a fortnight, not being satisfied with his condition, he consented to have ether administered, and a more thorough examination made of his injury, the conclusion arrived at being that there was a fracture of the upper end of the right femur. Three days afterwards he became sick; the next day he vomited blood and had abdominal distension, and on the following day suppression of urine, death ensuing in the evening, with his intelligence unimpaired to almost the last moment.

Mr. Gamgee was born at Florence in 1828, and was consequently in his fifty-ninth year. The son of an eminent veterinary surgeon (still living in Edinburgh), at first he was destined for the same calling, but subsequently he became a student at University College and entered the medical profession, studying afterwards at Paris, Pavia, and Florence. During this course of education he gained that mastery of languages which in after-life adorned his career, and made him a facile exponent both of the writings and teachings of continental authors, especially French and Italian. This art also led to his appointment as corresponding member of several foreign learned societies, and gave him the opportunity of supplying abundant contributions to the literature of his profession from many sources. Exhibiting in his student days the promise of an exceptional and brilliant career, he became surgeon to the Queen's Hospital, Birmingham, in 1857, a post which he held until his illness in 1881, when he was appointed consulting surgeon.

Into the conduct of his duties at the Queen's Hospital he threw himself with intense zeal and activity, and in both the professional and administrative work labored unceasingly to promote the reputation and welfare of the institution. The extension of the hospital and the origin of the Hospital Saturday collections were mainly owing to his influence and exertions, and in the details of these movements he gave valuable assistance and incessant labor. While president of the Medical Institute, by his unwearying devotion, he added largely to the library and the fund connected with it; and as president of the Birmingham Branch and Midland Medical Society he worked ardently in their respective interests. Among his writings were a work "On the Treatment of Fractures and on the Treatment of Wounds," and various monographs—"Harvey and Cæsalpinus," "Vivisection and Human Surgery," "The Hospital Saturday Movement," etc. As a strenuous advocate of treating wounds by dry and infrequent dressing, rest and immobility, his teaching was expressed in a form which exhibits a wide knowledge of surgical literature and his complete mastery of fine and graceful writing.

Mr. Gamgee was much more than a great surgeon; as a citizen and as a man he left a strong impress not only on his own com-

munity but on the tone of his profession everywhere. Many Americans who have seen him in his own home will retain pleasant memories of his hospitality and kindness to them. He was an honorary member of the Massachusetts Medical Society.

Correspondence.

SUBCUTANEOUS INJECTION OF SALT SOLUTION.

VIENNA, Sept., 29, 1886.

MR. EDITOR, — I lately witnessed the subcutaneous injection of 50 ccm. of a salt solution into the body of a boy seven years old, by Professor Monti, and believing it may be of interest to your readers and perhaps at some time useful, I send you this brief description of his method. The requisites are, a piece of rubber tubing about six feet long, a large hypodermic needle and a graduated beaker containing a solution of salt. The salt solution is heated to 100° F., and then placed about four feet above the patient on a stool that rests on the top of a table. The hypodermic needle is attached to one end of the rubber tubing. The tubing is filled with water, and one end is inserted into the salt solution, then the needle end of the tube is lowered and the contents are allowed to run off until the stream becomes warm from the salt solution in the beaker. The needle is now inserted into the subcutaneous tissue while the stream is flowing. At this moment an assistant reads the level of the fluid in the beaker. This done one can tell exactly by means of the scale on the beaker how much of the solution has been injected. The tissue is distended by the fluid forming a tumor which disappears in the course of an hour or two. In the case I saw the injection was made an inch and a half below the naval, and a half inch to the right of the median line. The swelling was an inch and a half in diameter and about half an inch in height. The whole time occupied in giving the injection and making the necessary preparations did not exceed twenty minutes. The method has been employed in the collapse of cholera infantum and may further be found useful in some of those cases where intravenous injection has formerly been resorted to. Yours truly,

ALBERT H. TUTTLE, S.B., M.D., (Harv.)

FOURTEENTH ANNUAL MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION AND CONFERENCE OF STATE AND PROVINCIAL BOARDS OF HEALTH.

TORONTO, ONT., Oct. 8, 1886.

MR. EDITOR, — The meeting of the American Public Health Association has this year a peculiar significance in its assembling for the first time without the limits of the United States. It has grown beyond the anticipation of its founders, and now embraces nearly the entire continent in its membership. Progress in sanitary matters in the Dominion has been rapid during the past four years, and the terrible scourge at Montreal in 1885 served to increase the zeal of public health authorities, and induce our provincial neighbors to seek the aid and support of the Association.

The Conference of State Boards of Health is a distinct body, which during the past three years has met at the same time and place with the Association. It is a deliberative body, composed of representatives from the State and Provincial Boards of Health. Its purposes are quite similar to those of the Association; so much so, in fact, that a decided movement was made this year to unite the two bodies, by making the Conference a Section of the Association. The measure was defeated.

The Conference met on Monday, October 4th, at Queen's Hotel, and spent the day in the consideration of various subjects pertaining to the administration of sanitary authorities both general and local. The objects attained by the Conference may be summed up briefly as follows:

A series of resolutions commending the plan of interstate notification of infectious diseases. The recent outbreak of yellow-fever at Biloxi, Mo., and the small-pox epidemic at Montreal, were urged as illustrations of the importance of such a course. A resolution was adopted, disapproving the drainage plan of the State Capitol of Indiana. Other subjects discussed were: A summary of sanitary laws, the infectious nature of consumption, the organization of county boards of health, the regulation of medical practice, and the transportation of dead bodies. Resolutions upon the latter subject were rejected.

The Conference adjourned, after several brief sessions, to meet at Washington, D.C., in September, 1887.

The meetings of the Public Health Association were held at Shaftesbury Hall, except the meeting on Tuesday evening. The papers upon special subjects were valuable, while those which were of a general nature were not burdened with originality or usefulness. Fortunately, the latter were few in number.

The morning session of Tuesday was devoted to the subject of Sewerage and Sewage-disposal. It was attended by many of the citizens of Toronto, who are just now suffering with the throes of a civil earthquake in the shape of a proposed sewer question.

An excellent paper by Dr. George Baird, of Wheeling, W. Virginia, advocated the "Destruction of Garbage and Night-soil by Fire." The paper described the relative situations of Wheeling, Va., and Bellair, Ohio, the drinking-water of the latter place being polluted by the night-soil of the former place, showing the folly of the claim that a running stream of water will purify itself in a few score feet. With greater care for the health and comfort of their neighbors, than is usual in the case of contiguous cities, the city of Wheeling undertook a series of experiments and finally succeeded in constructing a furnace which was eminently satisfactory, the night-soil being mixed with fine coal before burning. Natural gas is also employed in reducing the material.

At a later meeting the same writer offered another paper upon the subject of "Sanitation in the Matter of Street-Paving."

Toronto, like Chicago, draws its water-supply from the same lake into which its sewage is poured. Hence the local interest in the subject of sewerage. The papers presented by local physicians and engineers were of a high order of merit, treating the subject both in a general manner and with reference to the special needs of Toronto.

Dr. G. B. Thornton, of Tennessee, offered a paper entitled "Six Years of Sanitary Work in Memphis," in which he detailed the operations of the health authorities in that city which had been undertaken since its last great visitation by yellow-fever. Special mention was made of its sewerage system. The paper was followed by discussions by Cols. Waring and Hadden in further explanation of the plan which had been adopted.

Dr. D. E. Salmon, of Washington, D.C., read a paper on "Recent Progress in the Investigation of Hog Cholera." He said recent discoveries showed the disease was caused by bacteria. Sterilized culture liquid used as an inoculant was found to protect pigeons against the living germs. The experiment had not been yet carried out to a conclusion in regard to protecting hogs. The microbes multiplied with extraordinary rapidity in water. This experiment showed these germs had power of multiplying in ordinary drinking-water, such as is taken from our rivers and streams. A solution of mercuric iodide — proportion one to two millions — was found to destroy the germs. The question therefore suggested itself whether the fluids and tissues of hogs could not be so impregnated with this disinfectant as to render them absolute proof against the bacteria.

Dr. A. N. Bell read the report of the Committee on the "Disinfection of Rags." The report was quite long, discussed other matters foreign to the subject, and provoked a lively discussion which lasted till midnight. The resolutions which accompanied the report were referred to the Executive Committee, and were finally passed, after being modified, at a subsequent meeting.

Excellent papers were offered on Thursday evening by Dr. Bryce, of Toronto, on the "Decomposition of Albuminoid Substances and some Sanitary Problems connected therewith." By Archibald Blue, Esq., on "Food in its Relation to the Distribution of Wealth," and also by Dr. H. P. Yeomans, upon "The Best Methods of Teaching Hygiene in the Public Schools, as well as the Means for securing Uniformity in such Instructions."

Dr. J. B. Russell, Health Officer of Glasgow, Scotland, who had been made an honorary member of the Association, gave a brief address in which he spoke in a happy manner of his impressions of American sanitation as compared with that of Scotland.

The Lomb Prize Committee reported that no prizes would be awarded this year, no essays or plans of sufficient merit having been offered.

I cannot close without special reference to the entertainment of welcome on Tuesday evening, and the President's Annual Address. The exercises were held in the Normal School building. Addresses of welcome were made by Dr. C. W. Covernton, Hon. A. S. Hardy, and Mayor Howland, of Toronto.

The admirable address of the retiring President, Dr. H. P. Walcott, was listened to with unusual attention.

The study of infectious diseases, criticism of faulty methods, and sanitary fallacies, State supervision of sanitary work, and appropriation for the same, the organization of boards of health, local and general, received due consideration. His allusions to local matters were timely and dignified.

Massachusetts was represented at the meetings by Drs. Walcott, Jones and Abbott, as delegates from the State Board and Drs. Durgin, Holt and Rice from local boards.

Deaths reported 2,343: under five years of age 997: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 580, consumption 296, lung diseases 150, diarrhœal diseases 254, diphtheria and croup 150, typhoid fever 82, malarial fever 46, scarlet fever 23, whooping-cough 21, cerebro-spinal meningitis 16, measles five, erysipelas three. From malarial fevers, New Orleans 12, New York and Baltimore eight each, Brooklyn and Charleston four each, Philadelphia two. From scarlet fever, Cincinnati seven, Brooklyn and Boston four each, Philadelphia and Pittsburgh three each, New York two. From whooping-cough, New York and Brooklyn seven each, Boston and Pittsburgh two each, Philadelphia, Cincinnati, and District of Columbia one each. From cerebro-spinal meningitis, New York eight, Springfield three, Cincinnati two, Philadelphia, Pittsburgh and Gloucester one each. From measles, New York four, Baltimore one. From erysipelas, Lowell two, Cincinnati one.

In the 22 cities and greater towns of Massachusetts, with a population of 1,032,650 (population of the State 1,941,465), the total death-rate for the week was 21 71 against 21.50 and 21.47 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,093,817, for the week ending September 18th the death-rate was 22.6. Deaths reported 3,942: infants under one year of age 1,656; acute diseases of the respiratory organs (London) 168, diarrhœa 925, fever 58, whooping-cough 49, scarlet fever 43, measles 32, diphtheria 25.

The death-rates ranged from 14.9 in Bristol to 40.8 in Norwich; Birkenhead 19.7; Birmingham 26.4; Hull 30.8; Leeds 29.1; Leicester 23.9; Liverpool 26 2; London 17.6; Manchester 31.4; Nottingham 24.4; Sheffield 27.9; Sunderland 26.6.

In Edinburgh 13.9; Glasgow 24.2; Dublin 27.5.

For the week ending September 18th, in the Swiss towns, there were 36 deaths from diarrhœal diseases, consumption 25, lung diseases nine, whooping-cough three, typhoid fever and puerperal fever each one.

The death-rates were: at Zurich 11.5; Geneva 9.1; Basle 14.8; Berne 10.7.

The meteorological record for week ending October 2, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps: —

Week ending Saturday, Oct. 2, 1886.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 2, 1886, TO OCTOBER 8, 1886.

GIBSON, JOS. R., major and surgeon. Granted two months' leave of absence, from September 25, 1886, on surgeon's certificate of disability, in lieu of the unexpired portion of the ordinary leave of absence granted him in S. O. 158, A. G. O., July 10, 1886. S. O. 227, A. G. O., September 30, 1886.

GARDNER, WM. H., major and surgeon. Ordered from Department of Texas to Department of the East. S. O. 227, A. G. O., September 30, 1886.

MATTHEWS, WASHINGTON, captain and assistant surgeon. Granted leave of absence for one month and twelve days, with permission to go beyond sea. S. O. 232, A. G. O., October 6, 1886.

FISHER, W. W. R., first lieutenant and assistant surgeon. Leave of absence extended one month. S. O. 230, A. G. O., October 4, 1886.

BORDEN, WM. C., first lieutenant and assistant surgeon. Relieved from temporary duty at Fort Bridger, Wyo., and ordered to return to his station, Fort Douglass, Utah. S. O. 126, Department of Platte, October 2, 1886.

KENDALL, WM. P., first lieutenant and assistant surgeon. Granted leave of absence for one month. S. O. 81, Division of the Pacific, September 24, 1886.

HAMMOND, JOHN F., colonel (retired). Died at Poughkeepsie, N. Y., September 29, 1886.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING OCTOBER 9, 1886.

JAMES SUARDS, medical director. Will convene Medical Board, October 6, 1886.

BROWNE, J. MILLS, medical director. Ordered to report to president Medical Board, October 6, 1886.

DEAN, R. C., medical director. Ordered to report to President Medical Board, October 6, 1886.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE FOR THE WEEK ENDING OCTOBER 2, 1886.

PURVIANCE, GEORGE, surgeon. Granted leave of absence for twenty-five days, September 30, 1886.

STONER, G. W., surgeon. Granted leave of absence for twenty-three days, October 1, 1886.

CARTER, H. R., passed assistant surgeon. To proceed to Galveston, Texas, as inspector, September 30, 1886.

AMES, R. P. M., passed assistant surgeon. Granted leave of absence for thirty days, to take effect when relieved, September 30, 1886.

WASDIN, EUGENE, assistant surgeon. Ordered to examination for promotion, September 20, 1886.

BROOKS, S. D., assistant surgeon. Granted leave of absence for thirty days, to take effect when relieved, September 30, 1886.

WILLIAMS, L. L., assistant surgeon. Relieved from duty at Mobile, Ala.; ordered to Marine Hospital, Wilmington, N. C., September 27, 1886.

PERRY, F. B., assistant surgeon. Relieved from duty at San Francisco, Cal.; ordered to Marine Hospital, St. Louis, Mo., October 1, 1886.

THE CHARLESTON MEDICAL SCHOOL.

The Medical Faculty of Harvard University, in response to an appeal from the Dean of the Charleston Medical School for aid in restoring their building shattered by the earthquake, have appointed the undersigned a committee to collect subscriptions for that purpose.

The undersigned will gladly receive any sums, however small, for this worthy object, which may be sent to,

HENRY P. BOWDITCH, *Dean Harvard Medical School.*
THOMAS DWIGHT, 235 *Beacon Street.*
J. COLLINS WARREN, 58 *Beacon Street.*

DEATH.

Died in Birmingham, England, September 18, 1886, Joseph Sampson Gamgee, F.R.S. Ed., M.M.S.S. Hon., aged fifty-eight years.

BOOKS AND PAMPHLETS RECEIVED.

Woman's Medical College of the New York Infirmary. Eighteenth Annual Catalogue and Announcement June, 1886.

Des Cataractes et de leurs Opérations. Conférences Cliniques Professées Par le Dr. Galezowski et Recueillies Par le Dr. Boucher Médecin-major de 1re classe. Paris. 1886.

A Treatise on the Practice of Medicine. By Roberts Bartholow, M.A., M.D., LL.D. Sixth Edition. Revised and enlarged. New York: D. Appleton & Co. 1886.

Handbook of Diseases of the Ear for the Use of Students and Practitioners. By Urban Pritchard, M.D. (Edin.) F.R.C.S. (Eng.) With Illustrations. Philadelphia: P. Blakiston, Son & Co. 1886.

Paralyses Cerebral Bullar and Spinal. A Manual of Diagnosis for Students and Practitioners. By H. Charlton Bastian, M.A., M.D., F.R.S., F.R.C.P. With numerous illustrations. New York: D. Appleton & Co. 1886.

The Artificial Feeding of Infants. By John M. Keating, M.D., Visiting Obstetrician to the Philadelphia Hospital, and Lecturer on Diseases of Women and Children. Physician to St. Joseph's Hospital. Fellow of the College of Physicians, etc. (Reprint.)

Zur Lehre vom Granuloma Fungoides. (Mycosis Fungoides Alibert.) Von Dr. Carl Hochsinger Secundararzt I. Cl. des K. K. Allgemeinen Krankenhauses in Wien, und Dr. Eduard Schiff, Docent für Dermatologie und Syphilis an der Wiener Universität. Wien. 1886.

A Text-Book of Human Physiology including Histology and Microscopical Anatomy with reference to the requirements of Practical Medicine. By Dr. L. Landois, Professor of Physiology and Director of the Physiological Institute, University of Greifswald. Second American, Translated from Fifth German Edition with Additions by William Stirling, A.M.D., Sc.D. With 583 illustrations. Philadelphia: P. Blakiston, Son & Co. 1886.

Lecture.

RENAL CALCULUS, ITS DIAGNOSIS AND TREATMENT.

BY JAMES TYSON, M.D.,
Physician to the Hospital and Professor of General Pathology and Morbid Anatomy in the University of Pennsylvania.

A CLINICAL LECTURE DELIVERED AT THE PHILADELPHIA HOSPITAL.

GENTLEMEN,— I wish to call your attention to-day to a subject of considerable practical importance and one which we do not often have the opportunity of treating in the way which I propose to-day. The subject is that of renal calculus: its diagnosis and its management. The immediate suggestion for this lecture is a case which recently came under observation in this house, and whose fatal termination and autopsy have given us the morbid specimens I propose to show you.

I shall in the first place briefly give you the history. The patient was a woman, forty years of age and married. She had no knowledge of her relatives. She had lived in a healthy country place for fifteen years. She has been married and enjoyed fair health up to eight months ago, when she began to have pain in the left side, with frequent and painful micturition. In the course of a month or two, these symptoms disappeared, but the pain returned at times. About one month before admission she awoke in the morning with violent pain in the left side. This pain continued and was accompanied by loss of flesh and frequent vomiting. The pain was increased by straightening out the legs.

The patient was admitted to the hospital March 24th, 1886, with this meagre preliminary history, complaining of a dull aching pain in the splenic region, tenderness over the spleen and over the left kidney. The temperature was 100°, and the woman was weak and nervous. The most tender spot was mid-way between the crest of the ilium and the lower border of the ribs. The urine contained an enormous amount of pus, fully one-third of its bulk.

In the history of this case we note the following points: extreme pain, varying somewhat in severity, but always present, tenderness, most marked midway between the border of the ribs and the crest of the ilium, and purulent urine. Under such circumstances, there is no difficulty in pointing out the organ affected. Given purulent urine with pain in the locality described and tenderness so distinct and so easily determined, there must be something wrong with the left kidney.

The next question naturally asks the cause of the suppuration? There are three principal causes of pus in the urine where the kidney is distinctly involved. These are tuberculosis of the kidney, impacted calculus and what is known as surgical kidney.

It is well known that tuberculosis may affect the mucous membrane of the pelvis of the kidney and gradually encroach upon the substance of the organ, infiltrate it and break down, infiltrate again and break down, and thus continue, until the organ may be converted into a cavity filled with pus, more or less inspissated, and the walls covered with cheesy miliary tubercles.

The so-called surgical kidney, is simply a suppurative affection of the kidney, the result of surgical disease. The term is not very well applied. It is usually the result of inflammatory disease of the bladder, the inflammation extending upwards along the ureter until the kidney becomes involved. This condition is produced by various causes, most frequently, probably, by stone in the bladder. Although a distinction is sometimes made between surgical kidney and the condition of the kidney resulting from impacted calculus, there is no essential difference in the nature of the process. Where suppuration occurs as the result of impacted calculus, the process is exactly like that where the inflammation is the result of extension from the bladder.

Which of these conditions had we to deal with in the case described? Under the most favorable circumstances, we are often compelled to allow this matter to rest in doubt. It occurred to us that taking the symptoms described in connection with the cachexia which this patient presented to a marked degree, there might be here tuberculosis of the kidney. Seeking further information on this point, the urine was examined for the tubercle bacillus, but none were found. We did not attach much importance to this, for although it is true that in tuberculous affections of the kidney the bacillus has been found, yet its absence cannot be said to exclude the presence of such disease. We therefore did not conclude from this negative result that tuberculosis was absent, and I must admit that I always inclined to the view that this was a case of tuberculosis. This view was favored by the absence of any definite history of nephritic colic. Where the suppurative process is due to impacted calculus, we usually are able to trace a long history of pain in the region of the kidney. In this instance we could obtain a history of pain dating back only eight months, and when the specimen is examined, this short history will seem still more surprising. Surgical diseases starting from the bladder and causing trouble in the kidneys, are accompanied by symptoms of irritation of the bladder. Nothing of this kind was present in this particular instance. Therefore taking all the evidence into consideration, while realising the difficulties of making a positive diagnosis, I felt that the probabilities were in favor of tubercular disease. As an aid to diagnosis, we introduced the aspirating needle in the region of the kidney, but the pus was not reached.

The woman gradually sank and died a few days ago, and I have the specimen here to show you. Extraordinary and astonishing as this may strike you, let me assure you that this condition with these symptoms is not infrequent. Here is a stone which was removed from this case, and it is one of the most remarkable specimens that I have ever seen. It has a base or trunk from which spring four principal prolongations. The base corresponds to the pelvis of the kidney and the four prolongations to the four calices. The extensions of the stone are further subdivided to correspond to cavities which they filled in the organ. It is of course unnecessary to say that this large calculus must have occupied longer than eight months in its formation. Whether or not careful examination earlier than eight months ago, would have given evidence of disease of the left kidney or whether the woman had had symptoms before this time and had forgotten them, matters not. The autopsy has revealed this extraordinary concretion

filling up a large portion of the kidney substance, with a history of only eight months pain.

Let us return for a moment to the question of diagnosis. It was plain to us that we had to deal with disease of the left kidney, but beyond this point there was acknowledged uncertainty, although there was a leaning towards the idea of tuberculosis. This proved to be erroneous. Are there any circumstances under which a more certain diagnosis is possible? There are, and it was partly with a view to bringing these to your notice that I selected this case as a text. If we had at any time been able to collect sediment from the urine, or small calculi or their fragments capable of analysis, the nature of the case might have been determined. The difficulties in the diagnosis of renal calculi are often much less than are commonly supposed, because their analysis is much easier than is commonly supposed. It is really a very easy matter to get at the composition of a calculus.

In the first place, under what circumstances would a renal calculus be suspected? If there is a history of excruciating pain in the region of the kidney, extending into the groin, paroxysmal in character, a pain which is so severe that words cannot describe it, you at once suspect that there is a stone in the kidney which is seeking to find its way into the bladder. I think that there is no condition which is likely to be confounded with this. Given a severe paroxysmal pain in the region of one or both kidneys, extending to the groin with retraction of the testicle in the male, I know of only one condition that can cause it. It is true that there is described in the books what is called neuralgia of the kidney, a condition in which there are the symptoms described without the presence of a stone. For myself I doubt the existence of such a condition as idiopathic neuralgia of the kidney. What has been termed neuralgia of the kidney is in all probability nephritic colic, depending on the presence of gravel. For practical purposes, therefore, we may throw out of the question nephralgia or neuralgia of the kidney.

It is also true that we have here severe muscular pains which might be confounded with pain in the kidney. The majority of persons who think that they have kidney disease have their attention directed to it by the occurrence of pain in the lumbar muscles which they attribute to the kidney, the idea being that renal disease is associated with pain over the kidney. In point of fact, real kidney disease other than calculus disease, is rarely attended with pain in the back. The pain of lumbago or rheumatism of the lumbar muscles is different from that due to impacted calculus. Under ordinary circumstances the former pain is not so sharp. It is true we have almost all experienced at one time or other a sharp lumbar pain momentary in duration, most frequently coincident with a sudden motion or twisting of the body. But this is of short duration as compared with the pain of nephritic colic. The other lumbar pains of rheumatism are not so severe, although they may be of long duration. They are greatly aggravated by any movement of the body. They are also more readily removed.

There is one other rare condition which produces pain like that of nephritic colic to which allusion should be made, and that is floating kidney. Sometimes a floating kidney is so loose that it twists upon itself, closing the ureter very much as a rubber-hose is obstructed when it is twisted upon itself. Such obstruction causes an accumulation of urine back of it and gives rise to intense pain which is quite like that of nephritic colic. This, therefore, should be remembered.

Having made the diagnosis of nephritic colic we must not stop here, for it becomes a matter of extreme importance in treatment, to ascertain the nature of the stone causing the irritation. A rational treatment demands this. And while we cannot always do it, we frequently can, indeed more frequently than is commonly done, and the treatment which is so often only palliative and empirical, may become curative and rational. Such a diagnosis demands the presence of sediments in the urine or the passage of a small calculus.

Where there are constant or repeated sediments of uric acid or oxalate of lime recognized by the microscope, we are thus at once informed of the nature of the stone. Sometimes a small stone is passed, the structure of which cannot be unravelled by the microscope. Other means must then be used to determine its composition. In the first place there is something in the appearance of a stone which will aid in the diagnosis. Taking this large stone, I have little doubt that it is a phosphatic stone, composed largely of phosphate of lime. It is exceedingly rare, in fact, I think it never happens that a stone with any other composition reaches this size. In the second place, the stone is white in color. This is the color of phosphatic stones, but also that of oxalate-of-lime calculi, although they never reach the size of this one. They are further characterized by their roughness. On the other hand, stones composed of uric acid and their compounds are apt to be smooth and of various shades of red; at other times they are fawn-colored and again white.

I have here some samples of stone which I shall examine. Here is a part of a stone which was removed from the kidney of a little boy, ten years of age, who died under my care. This boy had purulent urine for a long time and for years had suffered with pain. On two occasions stones were removed from the bladder by operation. After death this large stone was found in the pelvis of the kidney. Here are also other smaller stones, some of them smooth and others rough.

The necessary apparatus for analysis is simple. In the way of instruments, you need a little piece of platinum foil, and a pair of forceps to hold it, or a platinum spoon, a mortar and pestle, some nitric acid, acetic acid, hydrochloric acid and ammonia. A fragment of the stone to be examined is reduced to powder in the mortar. The piece of stone which I shall use is white in color. As I have said, the phosphatic stones are white, so are those of oxalic acid. Uric-acid stones are apt to have a reddish tinge, but they may be almost white on the surface, at least. In this case you will note that although the stone was white, the powder presents a reddish tinge. I place a small portion of the powder on the platinum foil and heat it in the flame of a spirit-lamp. Instantly the powder blackens and partially disappears. In a few seconds, it is entirely gone. I need not go a step further in the examination of this stone. Given a powdered stone which disappears upon the application of heat, what is it? It is either organic matter, or pure uric acid, or almost pure uric acid, or one of those extremely rare forms of stone, known as cystin,

xanthine and urosteolith. The first never assumes a stony hardness, and the last three are so rare that they do not occur in an average man's life. I have seen but one cystin stone and none of the others. It may therefore be concluded with almost absolute certainty that this stone is uric acid. But this may be rendered absolutely certain by another test, the murexide test. A little of the powdered calculus is placed on a plate and dissolved in nitric acid. Heat is then applied and the acid evaporated. A little solution of ammonia is next added and you observe the beautiful purple color which comes out at the point of contact. This proves that this is a uric-acid stone.

Suppose, however, that on the application of heat the stone does not entirely disappear? We should then again apply the murexide test and if we obtain the reaction, the stone must consist of uric acid in combination with bases, and clinically speaking, this is equivalent to uric acid.

Taking another stone, the composition of which I do not know; I powder it and heat it to redness on the platinum foil. It at once becomes black, but a considerable residue is left. I then take a small fragment of the original stone, and without powdering, place it in the platinum spoon, and again apply heat. You will recall that in these examinations the question practically resolves itself into this: Is the stone composed of uric acid, oxalate of lime, or phosphates? A stone made up of triple phosphates of ammonium and magnesium is characterized by the peculiarity of fusing on the application of heat — fusible calculus. This enables us to recognize such a stone. This particular example does not fuse.

We, therefore, know that it is not composed of triple phosphates. It does not burn up, it does not melt into a bead; it is, therefore, either phosphate of lime or oxalate of lime. If it is an oxalate-of-lime stone, it has, by the process of heating, been converted into carbonate of lime.[1] If it is a phosphate-of-lime stone, its composition has not been altered by the application of heat. To the burned powder I now add acetic acid; if it dissolves with effervescence, it is derived from an oxalate-of-lime stone; if there is no effervescence, it is phosphate of lime. The best way to apply this test is to put some of the stone, which has been heated, on a glass slide, and apply a thin cover. The acetic acid is allowed to run in at the edges. If it is desired, under the microscope, with a low power, the evolution of the bubbles of carbonic acid may be easily studied, but we shall adopt the rougher method without the microscope. No bubbles of carbonic acid are liberated. I conclude, therefore, that the stone is phosphate of lime. A very rare stone in man, although common in horses, is the carbonate-of-lime stone. This is recognized by treating the *original* powder with acetic acid, when it will dissolve with effervescence, whereas, the oxalate-of-lime stone does not dissolve with efferverscence until it has been heated to a red heat.

To recapitulate, you are to powder the stone and apply heat. If it disappears, it is in all probability uric acid, or compounds of uric acid. If there is any doubt, the murexide test may be applied. If the stone does not disappear upon being incinerated, it is composed either of phosphates or of oxalate of lime. If it is the triple, or ammonio-magnesian phosphate, the application of heat to a piece of the original stone will melt it into a bead; if it does not melt, it is either phosphate of lime or oxalate of lime. If it is oxalate of lime, the incineration will convert it into carbonate-of lime, which, in acetic acid, will dissolve with effervescence; if it is phosphate of lime, it dissolves without effervescence. Thus, with very little trouble, we may, with sufficient accuracy for practical purposes, ascertain the composition of a calculus. The bases are not ascertained, but this is not necessary.

Having determined the composition of the stone, what will be the treatment? The uric acid and oxalate of lime call for one treatment, the phosphates for another widely different. The latter is much more difficult to dissolve than the former. Uric acid is soluble in alkalies; oxalate of lime in neither acids or alkalies. Uric-acid sediments are thrown down in urine of acid reaction and dissolved by alkalies. The indication, therefore, is to give alkaline diluents, to render the urine alkaline, and if you do not cause the solution of the stone, you may, at least, prevent it from increasing in size. The experiments of Dr. Roberts, of Manchester, are almost too well known to be repeated. He imitated with alkaline solutions the dropping of the urine from the kidney into the bladder upon uric-acid calculi, and was able to effect a certain degree of solution. Whether this will take place in the body or not we do not know, but it is a rational method of treatment, and will tend to prevent the stone from enlarging, and as the passages enlarge, the stone may descend. The spasmodically contracted ureter, which grasps the stone, may, after a time, relax and permit the latter to drop into the bladder. If you can keep the stone from becoming larger, you favor this result.

The correct treatment for uric acid is, therefore, the alkaline treatment. For this purpose any alkali may be used, such as citrate or acetate of potassium. I prefer the citrate of potassium, in twenty-grain doses, four times a day, each time in eight ounces of water. Dilution is very important. It is of the greatest importance that you should, as it were, wash out the tissues of the patient with a tendency to gravel, in order to get rid of the *débris* of tissue metamorphosis. The introduction of large quantities of water into the system is an important element in the treatment. It is to the good effects of such treatment that the reputation of many of the mineral springs in the treatment of gravel is due. The introduction of plain water will accomplish this result as well as many of the spring waters. When, however, we come to springs like those of Vichy, which contain a large quantity of alkali, you can understand how useful they must be in the treatment of this form of calculus.

The same plan applies to the oxalate-of-lime calculus, but with less prospect of success, so far as solution of the stone is concerned. You cannot dissolve the oxalate of lime with acids or alkalies of such strength as it would be proper to use in the body. At the same time, the methods which prevent the formation of uric acid will prevent the formation of oxalate of lime. In the treatment of both of these varieties diet is of the greatest importance. In neither of them should the patient be allowed to eat a large amount of nitrogenous food, as meat or eggs. Fresh, succulent vegetables may be allowed in some cases, with a moderate amount of meat, or in bad cases, no meat at all. If there is one condition in which the

[1] For this, too high a degree of heat should not be applied. A long-continued white heat will calcine the oxalate of lime into lime; a red heat is sufficient to convert into the carbonate.

good reputation of a pure milk diet is justified, it is in the treatment of uric-acid calculus. So often have I been successful in obstinate cases of frequently-recurring uric-acid gravel with the pure skim-milk treatment, that it is the first thing that I offer the patient. I have noticed that if the skim-milk diet is kept up for a month or six weeks, and then stopped, the attacks of colic do not recur. In carrying out this plan of treatment, I recommend that during the first day, a glass of milk be taken every two hours. After this, the quantity is gradually increased until sufficient to satisfy the patient is taken. The quantity required to sustain life varies between three and seven quarts per day. It depends partly upon the size of the patient, and the amount of exercise taken. The milk acts both as a diluent and as an alkaline fluid. One set of vegetables should be avoided in the diet of persons having an oxalic diathesis, and that is those containing oxalic acid, such as tomatoes, sorrel, and especially the pie plant.

The importance of the diagnosis is shown in the fact that if the stone is composed of phosphates, the milk diet is much less valuable as a cure. The indication is here to increase the acidity of the urine, but while it is true that the phosphates are soluble in acids, it is, practically speaking, impossible to give acids in amounts sufficient to affect the calculus without injuring the system. By the use of benzoic acid, in ten-grain doses, the reaction of the urine may be rendered acid, and the further deposition of phosphates may be thus prevented, but nothing can be done towards dissolving the stone. Fortunately, most calculi are of the uric-acid variety. In phosphatic calculi, you can simply hope to prevent increase in size by rendering the urine acid, and in the course of time, if not too large, it may descend into the bladder. If too large for this, there only remains the operation of nephro-lithotomy, the growing frequency of which seems to be justified by its results.

OPERATIONS ON NERVES.

BY MAURICE H. RICHARDSON, M.D.,
Surgeon to the Massachusetts General Hospital, and to the Carney Hospital.

I. Resection and Suture. (*a*) Musculo-Spiral, (*b*) Median, (*c*) Ulnar.
II. Primary Suture. (*a*) Ulnar, two cases.
III. Excision for Pain. (*a*) Middle cutaneous of thigh, (*b*) Long-saphenous. (*c*) Inferior dental, (*d*) Infra-orbital.
IV. Stretching. (*a*) Spinal accessory for spasmodic wry-neck.

The cases recorded below were treated at the Massachusetts General Hospital during the past fifteen months, with the exception of the last, which was at the Carney Hospital. As will be seen, some of the cases are complete, while others are still under observation.

NERVE SUTURE.

Case I. Injury to median nerve from bursting of bottle. Healing. Painful neuralgia in fingers and thumb, with loss of power in thumb. Removal of injured portion, suture, relief of pain, and restoration of motor function.[1]

Patient, J. C., a young man, bar-tender, was injured by the bursting of a ginger-tonic bottle July 20th, 1885, in the left wrist in front. The cut healed readily, but there was loss of sensation in the middle and fore-fingers and the palmar surface of the thumb. Accompanying the loss of sensation there was severe pain in the thumb and palm of the hand. This symptom of severe pain led him to come to the Nervous Department of the hospital where Dr. Putnam examined him and recommended an attempt to relieve the symptoms by surgical means.

July 18th, 1885, operation with ether.

The median nerve was quickly exposed at the point where it was supposed to have received injury, about one and one-half inches above the palm. The nerve was found involved in the cicatrix and almost entirely severed, being united by only a few fibres. The whole nerve was isolated from the surrounding parts and the injured portion entirely excised by a transverse section above and below. The ends, which were sharply cut and clearly defined, were then brought into apposition and sewed together. Considerable traction was first used so that there would be as little tension as possible. A cat-gut suture was then passed into the proximal trunk half an inch above the cut, and brought out in the centre of the divided end. It was next introduced into the centre of the end of the distal part of the nerve and brought out half an inch farther along.

The divided sheath of the nerve was then brought into close approximation by fine cat-gut sutures, care being taken to include only the sheath itself. The wound was closed with silk, drainage provided for, and the arm and forearm placed upon an internal angular splint with the carpus well flexed. The wound healed rapidly, though not by first intention, and the patient was discharged August 11th, to the convalescent ward. There had been no change in his symptoms except almost complete relief of pain. There was still slight pain in the top of the thumb, ulnar side.

August 29th, 1886, a little more than a year later, I examined him. There was a prominence in the anterior carpal region at point of suture. Sensation was good in all parts supplied by the median. There was no pain and had been none for months. Finally, the muscles supplied by the median alone, *adductor* and *opponens pollicis*, were well developed and responded to the man's will. In this case, therefore, the functions of the nerve were completely restored.

Case II. Stab in back of arm. Division of musculo-spiral nerve. Wrist-drop. Suture of nerve stump, suppuration, erysipelas, no improvement at end of three months. Second operation. Resection and suture. Complete and permanent recovery after four months.[2]

George Donahue, laborer, forty-three years of age. Came to the Massachusetts General Hospital, May 19th, 1885, having been stabbed by an Italian with the blade of a pair of shears. The external wound was small. The triceps was cut and the musculo-spiral nerve severed. Two small pieces of bone were clipped from the humerus. Had wrist-drop and inability to extend fingers.

Dr. Warren enlarged the cut. The ends of the nerve were found and united with six small cat-gut sutures through the sheath. The triceps was sewed up with cat-gut. Drainage-tubes were left in wound

[1] Mass. Gen. Hos. Records, p. 73, vol. 220.

[2] Mass. Gen. Hosp. Records, Vol. 220, p. 108.

and sterilized cotton dressings applied. Arm put on internal angular splint.

After the operation some sensation along course of radial nerve was noticed. One month after, bad erysipelas and prolonged and extensive suppuration of whole upper arm. July 6th, Dr. Putnam found no reaction to galvanic current. Sensation was found over dorsum of hand. Strong wire brush current caused painful sensations everywhere supplied by musculo-spiral. Muscles were soggy and skin dry and hard. Voluntary motion of ulnar and median preserved, but feeble.

Reëntered hospital August 10th, for resection of the nerve, not being able to use arm, his condition being same as when discharged. At this time the case was examined by Dr. Putnam with me, and it seemed best not to wait any longer before making another attempt, on the ground that there had not been the slightest improvement or sign of any, and that the failure of immediate union, with prolonged and extensive suppuration of the neighboring parts, rendered it extremely improbable that any improvement in his condition would ever result.

It having been decided to make a second attempt, the patient was etherized and the musculo-spiral nerve exposed by a cut about six inches in length made over the normal course of the nerve at an angle with the scar of the stab. It was found running into the dense mass of cicatricial tissue by which the former wound was healed, and from which the distal portion of the nerve was with some difficulty found emerging. The nerve was divided above and below the old wound by a clean, sharp incision, and the cicatricial tissue with the excised nerve-end was dissected out. This specimen measured an inch and a half.

After thorough stretching of the proximal end, by which the nerve was quite materially elongated, the sheath was united with seven fine silk sutures threaded upon a fine cambric needle. The joint made in this manner was quite perfect. No suture was put into the nerve itself. The external wound was closed with silk, drainage established, and the whole arm extended upon a straight splint. The most careful antiseptic precautions were taken and the wound healed immediately by first intention under Dr. Warren's sterilized cotton dressings.

No improvement of any importance was observed up to the time of his discharge except that he could use his *extensor secundi internodii pollicis*. He was discharged to report to Dr. Putnam, whose patience in his treatment was rewarded about four months later by a complete restoration of the powers of the nerve.

Ten months after the operation I saw the patient holding a piece of iron pipe weighing more than a hundred pounds, which he was putting into a deep hole he had just dug in the streets.

Case III. Ulnar nerve completely divided by glass. Healing of wound. Motor and sensory paralysis. Resection and suture of nerve stumps. Union by first intention. Case still under observation.[3]

Mary Quinn, twenty-two years, single, domestic. August 10, 1886, patient came to hospital having previously cut wrist in putting her hand through a pane of glass. The wound had entirely healed. There was loss of sensation in little and half of ring fingers, while abduction and adduction of fingers was very slight. Patient was etherized and a cut made over the ulnar nerve on the radial border of the *flexor carpi ulnaris*. This cut was at right angles to the original wound. The ends of the divided nerve were only found after a long dissection as their relations were considerably altered and the distal portion of the nerve retracted some distance. The upper portion of the nerve was stretched as much as possible before refreshing the end, but it was found extremely difficult to elongate the trunk sufficiently to make it join the peripheral portion without considerable tension.

The stumps were united by eight fine silk sutures, passed upon cambric needles through the nerve sheath. The arm was placed upon a splint and carpus kept in flexed position. Two weeks later she was sent to the Convalescent Home, the incision having healed perfectly by first intention, with no constitutional disturbances, under antiseptic dressings. She was sent to the neurologist upon her discharge from the home and is now under observation, with as yet no apparent restoration of motor-power in the nerve, and without any disturbance from neuritis or other cause.

PRIMARY SUTURE.

Case IV. Laceration of arm just above internal condyle. Ulnar and internal cutaneous nerves torn. Suture of ulnar. Union by first intention. Case under observation, symptoms as yet negative.[4]

Bartholomew Lynch, entered hospital July 8th, with left arm lacerated half an hour before admission by being caught in a flying belt. There was a ragged wound of left arm two inches above internal condyle. The wound extended from near the middle line in front around to the back of the arm, dividing the ulnar nerve, basilic vein and part of the *triceps* muscle and tendon. The wound was filled with dirt and blackened grease. After prolonged searching the stumps of the torn nerve were found. The ragged ends were carefully cut off above and below, three-fourths of an inch of nerve being thus sacrificed. Both portions of nerve were stretched with as much force as it was possible to apply, and the sheaths were united with fine silk sutures.

The *triceps* muscle and tendons were united with cat-gut sutures and the external wound closed with silk. The forearm was extended upon a straight splint, the wound having been covered with iodoform and carbolic gauze. Discharged on the 19th to report to the neurologist. No improvement noticed when last seen, and no pain or discomfort from the operation.

Case V. Cut of wrist. Ulnar nerve, *flexor carpi ulnaris*, and ulnar artery divided. Ligature of artery, suture of tendon and nerve. Immediate union, absence of local and constitutional symptoms. Case still under observation.[5]

This patient came to the hospital August 10, 1886, with a fresh cut of the wrist, ulnar side, a short distance above the joint, caused by a piece of glass. The ends of the nerve were found and united by their sheaths, fine silk sutures being used. He was sent back to the out-patient room and made a rapid recovery, the wound healing by first intention. There was absence of all constitutional and local symptoms. He was then referred to Dr. Walton who reports today, eight weeks after operation, as follows: There

[4] Mass. Gen. Hosp. Records, Vol. 226, p. 53.

[5] Mass. Gen. Hosp., Out-patient Department.

has been no improvement as yet, although the area of anæsthesia has retracted a little.

NEURECTOMY.

Case VI. Cut over middle of right thigh. Pain in scar and along course of middle cutaneous branch of anterior crural nerve. Painful cramps in calf. Dissection. Branch of nerve found to enter scar. Excision of scar eight months later, and an inch of nerve trunk. Cure.

James Prento, thirty-three years. In August, 1885, cut his right thigh with an ice hook. There was, on entrance to the hospital, April 3, 1886, a small scar on the right thigh, six inches above the knee-joint, at its middle and outer part. There was pain at this point and he was tormented by frequent and persistent cramps of the muscles of the calf. He was seen by Dr. Walton, who considered the pain and cramps probably due to the scar in which it was thought some branch of the middle or external cutaneous nerve was entangled. An operation was therefore advised for the removal of the scar and a portion of the nerve, if any should be found.

A cut was made above the scar parallel to the usual course of the nerve. A small branch of the middle cutaneous nerve was found an inch or more above the scar and followed down into it. The scar itself was then dissected out and with it an inch of the central end of the nerve.

April 26th, patient discharged, wound being healed and the pain and cramps having entirely disappeared.

Dr. Walton, to whom the case was referred after discharge from the hospital, reports as follows: The pain which existed to a greater or less extent before the operation went away. The cramps ceased. A patch of anæsthesia was found below the scar in the parts supplied by the excised branch.

Case VII. Cut on inner aspect of foot, of four years' standing. Pain in scar referred along course of internal saphenous nerve; dissection. Branch of nerve found involved in scar. Renewal of scar and portion of nerve; cure.[6]

John Sullivan, aged forty-eight, had a painful scar on the inner aspect of the left foot, from a cut four months before. Suffered a good deal of pain in the region of the scar, of a lancinating character. Referred to me by Dr. Walton. I found, on cutting down upon the probable course of a branch of the long saphenous nerve, a small filament, which, when followed, was found to enter the cicatrix. An inch of the nerve was excised, and the scar itself. A complete cessation of the pain followed immediately.

Case VIII. Neuralgia of inferior dental nerve for five years. Division of nerve inside mouth; relief for two years. Return of pain in aggravated form, lasting one year. One inch of nerve destroyed by opening inferior dental canal from outside. Immediate recovery and cure.[7]

S. P. B., seventy-two years old, entered September 3, 1886. Eight years ago, developed severe neuralgia in the right side of the face, over the lower jaw. Three years ago, inferior dental nerve was divided just above the point where it enters the dental foramen. This operation gave relief for two years, when the same trouble returned.

August 4th. One inch of the inferior dental nerve was cut out. An incision parallel to, and through the fibres of the *masseter* muscle, three inches in length, was made down to the jaw-bone. With a gouge and mallet a narrow opening, one inch long, was made through the ramus of the jaw over the dental canal. The nerve and artery thus exposed were cut at each extremity of the opening, and the whole curetted out. There was little hæmorrhage. The external wound was closed with silk, and iodoform dressings applied.

Two days later, stitches and drainage-tube were removed. For some days after the operation there was complaint of slight pain in the parts supplied by the mental branch of this nerve. This rapidly disappeared. He was discharged on the 10th.

August 25th. Came and reported that "it was a real pleasure to live; that he had had more real pleasure in life since leaving hospital than in any ten years before."

Case IX. "Epileptiform neuralgia" of side of nose and face. Neurectomy of infra-orbital nerve; complete cure.[8]

Tim O'Brien, sixty, married, laborer; entered hospital, August 8, 1885, with history of trouble in face for sixteen years. Some years ago had an operation done in an English hospital, without relief. Has pain in right side of face and nose, in parts supplied by the infra-orbital nerve. This is spasmodic, and extends from the inner canthus of eye down to the ala of the nose. During this paroxysm he leans his head upon his hands, with evidence of great pain, and the muscles of the nose contract spasmodically upon the right side, drawing up the ala and wrinkling the skin.

August 12th. Under ether, the infra-orbital nerve was found, a needle having been first inserted into the infra-orbital canal. The nerve was pulled out of the canal as far as possible, and cut. The peripheral end was then drawn up, and its branches dissected down an inch or more, and then divided.

The next day patient reported himself very comfortable, with pain much relieved. What pain still existed was referred to the ala of the nose.

August 18th. Five days after operation the pain had entirely left the face.

August 21st. No return of pain; face healed. Discharged.

NERVE-STRETCHING FOR SPASMODIC WRY NECK.

Case X. Spasmodic wry neck, probably of central origin; rapid and uncontrollable contraction of right sterno-mastoid. Constitutional treatment a failure. Head made immovable in plaster-of-Paris helmet; failure. Spinal accessory nerve exposed and stretched. Right sterno-mastoid becomes perfectly quiet, but left becomes affected; patient much improved. Spasm returned two months later to less degree.[9]

James Dutton, twenty-eight years old, weaver; April 10, 1886, entered Carney Hospital. Previous history good. Eight months before entrance noticed a slight twitching of the neck, which would appear at intervals of a week or two. Stimulants or lying down would stop the twitching. Never any trouble in swallowing; no venereal disease. The left side of the neck seemed enlarged and swollen. There was a distinct swelling behind the posterior pharyngeal wall, which looked red, and felt brawny. Two days after entrance the lump in pharynx was aspirated; no pus.

[7] Mass. Gen. Hosp. Records, Vol. 226, p. 163.
[8] Mass. Gen. Hosp. Records, Vol. 220, p. 100.
[9] Carney Hospital Records.

April 26th. Head put into stiff bandage, which kept him steady and comfortable.

June 19th. Head-gear was removed, and head found to shake as much as ever. Became despondent and suicidal.

From July 1st to August 3d, was put upon large doses of quinine, salicylate of soda, and iodide of potash without benefit.

After consultation with Dr. Bullard and the staff, and at the patient's earnest request, it was decided to try stretching of the right spinal accessory, as the twitching seemed to be mostly in the right sterno-mastoid. Operation under ether.

An incision, four inches in length, was made from the mastoid process downward and forward, along the anterior border of the sterno-mastoid muscle. The dissection was carried directly backwards toward the vertebræ, until the nerve was exposed. Continued and repeated tension was put upon it by means of hooks and the fingers. By measurement, ten pounds weight was applied. Dr. W. N. Bullard tested the nerve with the electric current after each stretching, but at no time did the sterno-mastoid and trapezius fail to respond. The wound was closed antiseptically, and the union was immediate.

The next day the twitching had entirely disappeared, and the muscle remained perfectly quiet for two months. The left sterno-mastoid, which had been perfectly quiet before, now took upon itself an action precisely similar to that which had existed in the right, but less in degree.

Examination, October 11th, shows that there is still rapid contraction of the right sterno-mastoid, though much less than before the operation. His general condition is much improved, and his discomfort is quite trifling.

The first suggestion that the ends of a divided nerve be sewn together in order that the interrupted functions of the nerve might become re-established, dates back many years. "The union of the ends of a divided nerve had already been proposed by Wilhelm von Saliceto and Guy Chauliac in the last century. Arneman mentions this subject, and as it appears was the first to study the operation experimentally. Unfortunately, according to this author's statements, his first attempts were failures, and it is highly probable that owing to this lack of success the nerve suture found for a long time after Arneman no surgical support. Up to the twentieth year of our own century but few authors had occupied themselves with this operation, and their researches were, moreover, so incomplete that they could do but little towards the further solution of the question. (Delpeich, Collisan, Lemmering and others.)

"Flourens, however, published in 1828 the results of his experiments, among which several made upon fowls were so successful that they enabled him to determine that a primary union took place between the ends of a divided nerve, and that the same occurred immediately following the application of the suture.

"Larrey at the same time found the central ends of two nerves in an amputation stump completely grown together. Surgically the operation remained for a still longer time without any application, and but a very small number of cases are to be found in the literature of the subject,[10] and they are obscurely reported and scantily described, the operators satisfying themselves with their mere mention."

The present stage of the operation began in 1864, with the work of Weir, Mitchell, Velatin, and Langier. This work has been carried on to the present time by numerous writers until the literature of the subject is very extensive. While most writers agree that the suture of divided nerves should be done, others reject entirely the operation.

The indications for nerve suture is generally considered to be when the wound is such that the divided ends do not fall naturally together. When the adjacent parts keep the distal and peripheral stumps in their normal position, and the ends are only separated by the natural retraction of the nerve itself, it is thought that the restoration follows as well as when suture is employed, and that there is less danger of neuritis and other complications.

I believe that suture should be employed in all cases where important nerves are divided, because in no recorded cases have serious local or constitutional symptoms been observed, and because it is only in this that we can hope for a primary intention. In all the cases recorded above, except Case IV, the cut has been a clean incision. Yet, in dissecting down to find the retracted ends or the cicatrix, it has been found either that the nerve ends were so placed as not to fall together or even near together, or when cicatrized that the normal nerve tissue was interrupted by a very considerable interval of dense cicatricial tissue, through which the regenerations must take place. Nevertheless, it is true that a nerve may regain its functions even when the stumps are separated a long distance and no sutures have been applied.

THE OPERATION.

In primary suture it is often difficult to find the ends of the nerve. In Cases IV and V this trouble was met with. The dissection then should be made well above and below, where the nerve preserves its normal relations. This very fact (difficulty of finding nerves) confirms my belief that the nerve ends do not readily fall together.

The ends having been found, if clean-cut they should be stretched sufficiently to make any longitudinal tension impossible,— so that when sutured the nerve will lie in the bottom of the wound, lax and tortuous. This is aided by flexion or extension of the nearest joint, as may be required.

In lacerated wounds where the ends of the nerve are torn and bruised, a clean-cut surface should be made with a sharp bistoury. The use of scissors for this purpose I do not think best because the nerve fibres are crushed between the blades instead of being cut. If it is necessary to remove a very long piece of contused nerve — an inch or more — it is better to leave the contused end rather than trust to great elongation, or to the efforts of nature to fill the gap. In Case IV so large a piece of nerve was excised for this reason that it was found extremely difficult to bring the ends into apposition, and if an unfavorable result follows it may be due to this fact.

In applying the suture the thread is either passed through the nerve itself or its sheath. Of the forty-eight cases collected by Rawa, twenty-one were of the direct variety, through the nerve itself, nine perineuritic, and the others not recorded. In eight

[10] Rawa in Kiew, Wien. Med. Wochenschrift, Vol. 35, p. 221, March, 1885.

cases of the direct, rapidly disappearing neuroses came on, and once or twice neuritis. The indirect (perineuritic) was followed in but two cases by nerve symptoms.

In Case I, both the direct and indirect method was used. In all the others the perineuritic.

This method I believe to be the better, though most surgeons incline to the direct, believing that a better and more thorough union of the stump surfaces is thus obtained.

It is for this very reason that I believe the indirect method the better. Nothing could be more perfect than the union of the stumps in my cases in the manner to be described. Though the number of sutures employed varies much with different men, the only accurate joining of the ends can be made by six or eight threads.

The material should be silk or cat-gut. Silk makes the better knot and neater joint and holds longer. The technique is as follows:

The nerve having been elongated as much as possible without injury to the stump, the ends are let fall into the bottom of the wound in the position they will naturally assume. This will give the anterior surfaces. A fine cambric needle is passed through the sheath, about one-eight of an inch from its cut edge, towards the end of the stump. It then is passed beneath the sheath of the other stump through its open end, and emerges one-eight of an inch from its edge. The knot is tied and the long ends of the thread left. The assistant takes these long ends and pulls gently away from the operator. This rotates both stumps enough for the placing of the second stitch. This in turn is pulled and the next applied. In this way the nerve can be turned enough to place the stitches into the posterior surface. The operation is completed by starting in the centre in front again and rotating the nerve in the other direction. The line of suture made in this way is as perfect as can be imagined. Its strength exceeds that of the direct method, and it may be relied upon to hold the nerve ends together until union is completed.

The prognosis is favorable in nerve suture when union by first intention takes place, though months or years may elapse before the function of the nerve is restored.

The cases of neurectomy and nerve stretching are offered as contributions to the statistics of these operations. The method used of excising the inferior dental from outside the face proved more difficult than was expected, owing to the depth of the wound, but was very satisfactory, and will doubtless be followed by a long period of rest from pain.

In finding the spinal accessory the best incision is along the anterior border of the sterno-mastoid. This should be carried down two or three inches from the mastoid process and the tissue divided carefully until the nerve is found, running obliquely outwards. Ten pounds weight was applied, and this seems to me about as much as a spinal accessory nerve of average size will safely bear.

REPORT OF PROGRESS IN ORTHOPEDIC SURGERY.

BY E. H. BRADFORD, M.D., AND R. W. LOVETT, M.D.

LATERAL CURVATURE.[1]

THE occurrence of lateral curvature at different ages is very fully discussed by Dr. Samuel Ketch. He quotes passages from the leading orthopedists to show that the prevailing idea is that it is a disease occurring for the most part about the age of puberty, the only authors who dissent being Adams, Eulenberg, Hueter and Shaffer. He takes exception to this idea and quotes Eulenberg's cases. In 1,000 cases of lateral curvature collected by him, 87 per cent. are recorded as beginning before the tenth year, 56 per cent. of all cases occurring between the ages of seven and ten. Ketch collected the cases of lateral curvature treated at the New York Orthopedic Dispensary within the last eight years. Of 229 cases, 189 were in females. It occurred from birth to the twelfth year in 52 per cent.; from the twelfth to the eighteenth year in 41 per cent.; from the eighteenth year upward in 3½ per cent.; period of appearance not noted in 2½ per cent. The youngest case was two weeks old. He concludes first, that rotary lateral curvature is principally a disease of childhood and may be congenital or acquired; and second, that puberty, except as a concomitant occurrence has no direct causative influence.

A NEW METHOD OF APPLYING THE PLASTER JACKET IN SCOLIOSIS.

Fraenkel[2] announces a new method based upon the necessity of over-correction of the lateral curvature. He insists upon the importance of this over-correction in other deformities (club-foot, etc.), and describes how it can be applied to the spine. The child must undergo a preliminary course of treatment directed to restoring flexibility to the spine; this is done by the ordinary methods of bending the child over the knee, and com-

[1] New York Medical Record, April 24, 1886.
[2] Berl. Med. Wchsch., May 8, 1886.

mon gymnastic exercises. When a moderate degree of flexibility is restored the patient is suspended in Sayre's sling, bandage swathes are stretched over the convexity of the two curves, primary and secondary, and carried off to the opposite side. An assistant then pulls on each side, over-correcting both curves and keeping up the over-correction until the jacket is applied and has hardened. He recommends the frequent reapplication of the jacket.

Petersen [3] claims to accomplish the same thing by the use of Barwell's sling while the patient is suspended; in this way much less assistance is needed.

LATERAL CURVATURE.

Landerer considers that scoliosis is to be regarded as a deformity resulting from supericumbent weight, as genu valgum is, and that all treatment shall be based on that fact. The chief factor in determining the attitude is the muscular system. In a new-born child the spinal column is straight, if the child is made to sit up, the head and spine bends forward, and a total kyphosis is presented; if, however, the child is held sideways the spinal column with the head falls sideways and a single lateral curve involving the whole spine is presented. In a child, when it becomes necessary to hold the head erect, in a similar position a double curve S-shaped would present itself, the force causing the upper curve being the muscular system. Heavy superincumbent weight alone is not sufficient to cause a lateral curvature if the muscular system is strong enough to hold the spine in a vertical position.

The spine in beginning lateral curvature is usually quite flexible and the erect position is to be maintained chiefly by strength of the muscles. Massage, the writer claims to be a ready means of developing the muscular strength. As a new exercise the writer advises that in suitable cases the patient carry a basket upon the head for five or ten minutes daily, steadying the basket with the hand of the depressed shoulder.[4]

STATISTICS OF LATERAL CURVATURE.

Kölliker [5] has had an opportunity to observe and classify 721 cases of true lateral cuavature. Of these 577 were in females and 144 in males. He found, however, that of the severe cases alone, the numbers of the different sexes were more nearly alike, and that in the most severe cases, the number of males predominate. Simple dorsal scoliosis is the most common form (381 cases) and the next most common form is the typical S-curve (172 cases), that is, with the projection of the right shoulder and left lumbar region — the reverse double curve was only seen in 22 cases.

He found, however, that of the single curvatures the convexity was more frequently to the left than to the right. The left dorsal scoliosis appeared to be the variety most readily healed.

CLUB-FOOT.

Ried [6] contributes the histories of seven cases operated on by him for severe club-foot by resection of the tarsus. The operations were said to have been followed by satisfactory results in all cases.

In opposition to many writers he is an advocate for extirpation of the astragalus with resection of the tip of the fibula in younger persons in cases of severe club-foot, and of wedge-shaped osteotomy in older cases with much distortion of bone, presenting his reported cases as proofs in favor of his argument. Wedge-shaped resection of the tarsus he does not consider advisable in younger cases; but removal of the astragalus he advocates together with section and removal of a part of the anterior process of the calcaneus and of the posterior surface of the cuboid, even in children of two years of age. The incision for the removal of the astragalus advocated is a curved one from the outer malleolus across the projection of the astragalus to the inner edge of the extensor tendons. If any thickening of the sheath of the tendons is present it can be trimmed off so as not to interfere with the healing process.

The foot should be kept in a fixation and correction apparatus after the operation, which should be worn some time.

In opposition to the views of Ried, Wolff [7] claims that better results can be obtained by the means of forcible correction with the subsequent wearing of a fixed bandage than by any operative measures. He cites a case of a patient nineteen years of age with severe congenital deformity—(talipes equino varus) — where a cure was practically accomplished in five months. In a second case, a paralytic deformity in a patient twenty-four years of age complete correction was accomplished in five weeks. The writer claims that in all cases complete correction is possible without the use of the knife in any other way than for tenetomy of the tendo-aphillis.

In a clinical lecture Dr. A. S. Roberts [8] gives some very interesting facts about the ætiology and varieties of club-foot. In speaking of the treatment of it he directs attention to the lateral deviation of the anterior part of the foot. Taking the medio-tarsal joint as a starting point, he found that the part of the foot in front of it made an angle with the part behind it that varied much in the different conditions. In normal feet the angle varied from 26° to 37°; in valgus it averaged only about 8°, in severe cases falling as low as 5°. In varus cases, on the other hand, the angle averaged 51°, and anything over 40° Dr. Roberts considers abnormal. The treatment advocated for the correction of varus and equinus is extension by Shaffer's shoes which are slightly modified by Roberts and are quite clearly figured in the article.

The article on club-foot by A. S. Roberts and Samuel Ketch [9] in Wood's "Reference Handbook," is a most complete treatise on the subject. An analysis, as to the frequency of occurrence, of several hundred reported cases leads the authors to the following conclusions:

(1) That it is most frequently found in males.
(2) That Talipes varus predominates.
(3) That the right foot is oftenest affected.
(4) That both feet are more frequently affected than one alone.
(5) That primitive forms are rare.

A very full discussion of ætiological theories follows and Berg's theory of arrested rotation is accepted as the most likely one. The history and literature of

the subject is presented in full. The treatment advocated is that which is identified with Dr. Shaffer's extension shoes, namely, strong force exerted by means of hinged-lever and screw apparatus applied daily for a few minutes at a time. The article is fully illustrated by cuts of the different varieties of the deformity and of apparatus.

Dr. Gibney,[10] in an article on "Club-Foot," discusses at length the question of tenotomy. The objections ordinarily made to it he formulates as follows: (*a*) that it weakens the foot; (*b*) that it tends to produce calcaneus; (*c*) that the cicatrices resulting from it make subsequent treatment unreliable; and (*d*) that it is a painful operation. He disposes of these objections with an answer to each one; some of the answers are, however, not very convincing. He then discusses the abuses of the operation, which have brought it into bad repute in many places. They are: (1) incompleteness of operation; (2) failure to correct or over-correct the deformity; (3) too early use of the foot in paralytic cases; (4) the use of tenotomy where there are cicatrices from old operations; (5) operation without after-treatment. If these abuses are guarded against, he advises the performance of tenotomy in most cases. The remainder of the paper is taken up with a discussion of the other methods, "rapid cures," tarsoclasis, open methods, and tarsotomy.

CLUB-FOOT.

Mr. Parker gives a brief *résumé* of the work on "Club-Foot," which was done by him, in connection with Mr. Shattuck, and reported by them to the Pathological Society. They started upon their dissections with the idea in their minds that either spasm or paralysis of the muscles was the cause of the deformity, but the deformity persisted after the muscles were dissected off, and not until certain ligaments had been divided was reduction possible. The ligaments cannot be said to be "shortened"; they are normal in structure, and give no evidence of having undergone any pathological process; they are simply shorter than normal. This is the only constant condition, but more or less inclination inward and forward of the head of the astragalus is apt to be present. The average angle of inclination in a normal foot is 38°; in talipes varus it averages 49°, reaching 64° in some cases. There is a more or less incurved condition of all the bones of the foot; the muscles of the foot and leg, the nerve-trunks, and the spinal cord are normal. The ligaments at fault are the inner ones, along the incurved side of the foot, and in severe cases, the long and short plantar ligaments. From the division of these ligaments in many suitable cases, Mr. Parker has had uniformly successful results.

Following are the rules for the division of the ligaments: For the inner one (which is the anterior part of the internal lateral ligament, described under the name of the astragalo-scaphoid capsule), a curved tenotome is entered just in front of the internal malleolus with the point toward the sole. The knife should be kept between the skin and the ligaments, and they are cut down upon with a sawing motion; the tibialis posticus and anticus muscles will naturally be cut at the same time. For the division of the plantar ligaments, long and short, the calcaneo-cuboid articulation is chosen. A knife is entered at the outer edge of this, and the line of the articulation is followed when both ligaments are divided at the same time. The operation should be wholly subcutaneous, and a plaster-of-Paris bandage applied at once, which holds the foot in its new position.[11]

[10] N. Y. Medical Journal, 1886, XLIII, 427.

FLAT-FOOT.

Humphreys[12] contributes a paper upon the "Mechanism and Pathological Condition in acquired Flat-Foot." The astragalus is the key-stone of the arch of the foot, the posterior pillar the os calcis; the anterior is formed by the scaphoid, cuneiforms, and the three inner metatarsals. The anterior pillar is, by its structure, more elastic and weaker, because it contains the astragalo-scaphoid joint. This joint, in addition to its ligaments, is strengthened by the tendons of the tibialis posticus and peronei muscles. Now, in long standing, the muscles become fatigued, fail to afford the necessary support to this joint, the ligaments stretch in time, and an extension of this astragalo-scaphoid joint takes place. In consequence of this altered relation of the pillars of the arch, the astragalus is changed in position, and, by virtue of its shape, it rotates inward, so that it falls inside of the plane of action of the tendo-achillis, and the foot is thereby weakened, and the muscles whose function it is to raise the ankle and heel on the fulcrum of the ball of the foot cannot do so. "It is a persistent over-extended and incurved condition of the chief joint of the tarsus." Moreover, the muscles on the tibial and flexor side of the foot become relaxed and enfeebled, and fail to afford the proper support, and, therefore, the extensors and peronei not being extended and used, become irritable and contracted, and add to the discomfort.

FLAT-FOOT TREATED BY OGSTON'S METHOD.

Franks and Stokes[13] report cases treated by astragaloid osteotomy. Franks performed Ogston's operation, refreshing of the astragalo-scaphoid articulation, and nailing the bones in a corrected position, and some stiffness in gait followed, perhaps on account of the fixed gypsum bandage, which was worn four months. Stokes considers Ogston's operation too severe, and prefers removing a wedge from the inner side of the neck of the astragalus, thus avoiding an anchylosis at the Chopart's articulation. The case was a successful one.

KNEE-JOINT DISEASE.

Dr. Judson[14] comes forward with a new and very simple splint for the treatment of tumor albus in children. After insisting on the importance of absolute rest in this disease, he proceeds to describe his new splint, which consists of a strip of malleable iron, about an inch wide, which runs the length of the leg and thigh in the middle line behind, being somewhat longer than the ordinary ham-splint. At the top and bottom of this, and at two equi-distant points, are riveted semi-circle steel bands, transversely bent, to fit the leg and thigh. It is, in fact, a skeleton ham-splint. It is bent to fit the outline of the leg, and secured by straps and buckles. Dr. Judson claims that a plaster or ham-splint holds the femur as if it were imbedded in a mass of jelly, and, therefore, fails to afford definite support, while in this splint the transverse steel arms approach much more nearly to the bone and therefore,

holds it more firmly. The apparatus is very inexpensive, and could be made by any blacksmith.

Clutton[15] describes a

BILATERAL CHRONIC SYNOVITIS,

occurring in children from eight to fifteen years old, which affects only the knees, and is clearly syphilitic in origin. He has seen and recorded eleven cases of this sort, in all of which the condition of the patients was such that there was no doubt of the existence of constitutional syphilis. The synovitis is painless, does not give rise to muscular spasm, and the affection is extremely chronic. It does not tend to go on to destructive changes, but it is, nevertheless, not very amenable to constitutional treatment.

LOOSE CARTILAGE.

Poulet and Valliard[16] have endeavored, in a long series of pathological and experimental investigations, to learn under what conditions loose cartilages are most frequently developed. They report that a foreign bony or cartilaginous substance in the joint is developed out of bone corpuscular elements, and originate either from traumatic causes, peri-articular osteophytes, from loosened fragments of the joint cartilage of separated pieces of fragments from the ends of the joints. Dry or deforming arthritis shows the most favorable condition for the development of loose cartilage, and should be regarded as a symptom of the disease. Beside this most frequent form of dry arthritis, there is also a variety seen chiefly in youth, attacking only one joint, and only at one point of this joint. A peculiar affection of an insidious course, which is otherwise little known, exists, and is active in separating pieces of cartilage from the ends of the joints. In such cases, the resulting foreign substance is held in a depressed symmetrical spot in each of the bones, forming the joint. Every bony, foreign body may undergo changes in shape and structure, differing as the body may be free or pedunculated. The latter are inclined to a fibrous change, while the free bodies may undergo a cartilaginous change on the periphery, so that a substance originally bony may become partly cartilaginous, and further, this cartilage may proliferate.

A CASE OF OLD DISLOCATION OF THE KNEE BACKWARDS.[17]

Karewski reports a most unusual case of this rare deformity. A woman thirty-two years old, presented herself with an old deformity of the knee, resulting from a severe injury received when sixteen years of age. A complete dislocation of the knee-joint had taken place backward which from the presence and size of a scar, it was evident that the dislocation had been a compound one. The condyles of the femur were markedly prominent in front, covered by a cushion of fat on the under-joint surface. The patella is dislocated downwards. The edge of the tibia projects backwards, and in a measure the upper-joint surface can be felt.

Motion at the joint was perfect and the woman had been able to earn a livelihood as a serving-maid. Some arrest of growth of the tibia had been caused by the accident. The affected tibia was 3 cm. shorter than the other, in addition to the shortening due to the luxation. According to the history the patient had remained several months in bed after the accident and gradually learned to walk without using crutches. She complained of lateral laxity of the joint, and suffered from one attack of hydrops articuli in consequence.

(To be continued.)

Clinical Memorandum.

PLACENTA PRÆVIA PARTIALIS.

BY W. D. BIDWELL, A.M., M.D., OF LEAVENWORTH, KANSAS.

Mrs. P., a short, stout, healthy woman, twenty-six years old, was married two years ago last February. In July of that year she was taken with flooding after a hard day's work, which was followed by a miscarriage of a three-months' fœtus.

She became pregnant a second time about last Christmas. In May of this year she had a hæmorrhage, without pain, about equivalent to an ordinary monthly sickness. At this time she supposed she was only three months pregnant. In July she had another slight flow of about the same amount. September 7th, while stooping over, she began to flow, and lost about a quart of blood. She at once went to bed, and applying cold cloths locally, succeeded in stopping the flow. From that time she was about the house again till the 13th, when she felt languid and tired, and had to rest. At 12 o'clock, at night, without any pain or other warning, she began to flow freely, in spite of cold applications, and by the time I arrived, at 3.45, had lost some four or five quarts of blood.

Examination showed that the abdomen was nearly as large as at term, the cervix was long and soft, the os slightly patulous, and admitting the end of the finger. On the right side the uterus felt soft and boggy, while the head of the child could be felt on the left. After obtaining the above history, I informed the family that it was in all probability a case of placenta prævia. They were quite positive that the woman was only seven months pregnant, and as, in my opinion, it was advisable to deliver the woman at once, I asked Dr. Brock to see the case with me.

After consultation, it was decided to tampon the vagina, and watch the case closely. At 5 o'clock, September 15th, the pulse was 110, hæmorrhage still continued, and there were one or two uterine contractions. At 11 o'clock, it was evident to all concerned that something must be done, and the scruples of the family being at last removed, I dilated the cervix manually, and introducing the hand into the uterus, seized the right foot, rupturing the membranes at the same time, and performed version. The presence of a foreign body set up forcible contractions, and the child was soon delivered, though the rigidity of the perineum caused a moment's delay. The child, a female, was well developed, but still-born, and all attempts to resuscitate it were in vain. After the placenta was expressed by Credé's method, ergot was given in full doses every half-hour, till three doses were taken, and directions were left to give it if there was any return of the hæmorrhages. Twenty-four hours later the patient had a slight chill, though she had taken quinine immediately after delivery. Forty-eight hours later, after taking more quinine and opium, there was no return of the chill, the temperature was 99°, appetite good, and the patient feeling first-rate.

Two days later the temperature fell to normal, and the woman has made a perfect recovery, gaining strength rapidly.

Had we suspected that the child was so near full term, the method proposed by Dr. Bishop in the *Medical and Surgical Journal* of September 9th would probably have bettered the chances of the child being born alive, but taking into consideration the weakened condition of the woman and the danger from further hæmorrhage, the quick delivery by version gave the mother a better chance. Examination of the placenta showed that a surface four inches long and one and a half wide had been separated, thus exposing a considerable surface of open vessels, from which the hæmorrhage had come.

This case resembles the majority of cases of placenta prævia in the implantation, being mostly on the right side, but differs from them in that it occurred in a multipara, who had had but one miscarriage, and that some months previous to the second conception.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

October 11th, 1886, the President, Dr. F. W. Draper, in the Chair.

Dr. James B. Ayer reported a case of

WHOOPING-COUGH AT THE AGE OF FIFTY-ONE. TREATMENT BY CRESOLENE.

Last May, his patient, fifty-one and a half years old, father of two boys who were then afflicted with whooping-cough, was prostrated by a severe attack of bronchial catarrh, involving the whole respiratory tract down to the minute bronchi.

On the tenth day the convulsive stage began. The paroxysms, preceded by a feeling of oppression about the larynx and accompanied by nausea, were, the speaker could testify from observation, typical of whooping-cough.

The patient was convinced that he obtained great relief from the vapor of cresolene; nevertheless, the paroxysms continued daily up to the end of the twelfth week, and at the present time (twentieth week) they occur occasionally. He remembers having had an attack of the disease when eight years old. During the past few months Dr. Ayer has heard of many cases of whooping-cough among adults in this city.

Dr. J. C. Warren said that crysolene is a coal-tar preparation. It was shown here some two years ago by Mr. Andrews. It always seems in his experience to give relief.

Dr. C. P. Putnam said that he is somewhat skeptical about the value of the drug. It has appeared to do good at first, and has then failed. Possibly, because it was a novelty, he was overinclined at first to attribute to it any relief that might be observed. At any rate, he has used it many times and is entirely unable to say whether it has or has not any effect.

Dr. M. H. Richardson, speaking of the possibility just mentioned by Dr. Putnam of being deceived by improvement following the use of a drug, said that he had thought that a patient of his was receiving benefit from the dragées of Rabuteau, until it was discovered that they were being discharged undissolved through a fistula-in-ano.

Dr. M. H. Richardson then read a paper on

OPERATIONS ON NERVES.[1]

Dr. C. B. Porter said that the literature of the subject was well covered by the paper. The observations of Dr. J. J. Putnam and Dr. Walton have thrown a good deal of light on the subject of nerve suture, and by long perseverance with electricity they get good results in cases which would formerly have been considered hopeless. He had on one occasion sutured the ulnar and the median nerves in one operation, and had supposed that he had a failure, this being three or four years ago; although to-day he would persevere longer with the use of electricity. Again, to-day he would not suture both nerves at the same time, because of the impossibility of getting the greatest possible relaxation of both at once. He had in mind one case of suture of the ulnar, in which there was a return of sensation in two or three days, at least the patient said so, but no permanent improvement. He referred to cases of excision of the supra-orbital and infra-orbital for neuralgia, with relief which has lasted completely for a year; and to a case of painful stumps after amputation, in which removal of the stump of the great sciatic, small sciatic, and long-saphenous had given complete relief.

One young man had become a morphia-eater because of the painful stump after amputation of the thigh. Dr. Porter had determined to first break him of the opium habit and next to amputate the nerve stump. The patient therefore entered the Massachusetts General Hospital, but by the time that he was broken of the opium habit, his neuralgia had disappeared; it having been probably aggravated by the low condition kept up by opium eating.

Dr. S. G. Webber said that he had no surgical experience with the nerves. It seems wonderful that restoration of function should take place over considerable spaces, even a quarter of an inch. If operation cannot bring the severed ends of a nerve together, as in the case of a crush, the nerve fibres may bridge the space, and this result is, he thinks, worth trying for. Often if but one nerve be cut, although there is less motion, the injured man learns to use other muscles and so preserves good use of the limb. This is more likely to be the case with the ulnar than with the radial.

The speaker thinks that nerve stretching might be more often done for torticollis, for the symptom is a distressing one; the operation has produced good results, and even partial relief is a great blessing, while scarce anything else does good.

Dr. E. H. Bradford stated that as far as his recollection served, the reported success of the operation of stretching the spinal accessory in spasmodic torticollis was not encouraging. Some cases had been reported as cured after section of the nerve.

Dr. Bradford mentioned stretching the sciatic in a case of severe pain along the course of the nerve in a powerful adult, suffering from disease of the hip joint. Mr. McNamara had suggested and performed the operation, with the idea of temporarily paralyzing the irritated muscles and giving rest to the joint when acutely inflamed, as the sphincter ani is stretched in

[1] See page 368 of this number of the Journal.

hemorrhoids. In Dr. Bradford's case the relief was marked.

Dr. J. C. Warren said that it was of interest to inquire how long after injury an operation may be successful. He thought a case had been reported of stretching of the spinal accessory for severe torticollis in sleep, some fourteen years, he thought, after the injury, but without much success. He said also that Mr. Annandale's directions for exposing the nerve are different from those of Dr. Richardson. He makes his incision on the posterior border of the sterno-mastoid muscle on a line with the thyroid. Here the nerve is found easily in the cadaver, and there are no large vessels exposed, as he supposes would be the case in Dr. Richardson's operation.

Dr. Richardson replied that it is not necessary to expose large vessels, if the anterior border of the muscle is closely followed.

Dr. James J. Putnam spoke of the absence of danger of neuritis in operations upon nerves when done under antiseptic precautions.

The principal danger in operation for stretching seems to be that of setting-up chronic changes in the spinal cord. With regard to the strain that nerves will bear he had found that so slender a nerve as the facial would bear a strain of nearly twenty pounds before breaking. If desirable, stretching or crushing may be made as effectual as section, in interrupting the conducting power of the nerve and causing degeneration of the lower end, and it has the advantage of securing an eventual restoration of function,— where this is desirable — with greater certainty.

It is probable, as Ranvier has shown, that repair of cut nerves really takes place by a growth of fibres from the central end, and may take place so long as this remains in good condition. In the case reported by Dr. Porter, of secondary suture of the median and ulnar, the speaker had examined the excised piece, which consisted of a dense mass of connective tissue, and had found an abundance of healthy nerve-fibres in the upper end of it but none in the lower end, though a number of months had elapsed since the injury. Ranvier has shown that nerve-fibres may make their way through a certain amount of connective-tissue lying between the cut ends of nerves in certain animals, but experience seems to show that this is not true of the dense cicatrices which form after serious injury of the larger nerves in man. Speaking of complex, coördinated spasms, like torticollis, he said it was important to find and connect every underlying constitutional taint before or beside operating on the nerves.

In a severe case of torticollis observed recently, the speaker had found lead in both the drinking-water and the urine.

THE NEW YORK ACADEMY OF MEDICINE.

Stated meeting, October 7, 1886.

SOME PHASES OF CEREBRAL SYPHILIS

was the title of a paper read by Dr. Julius Althaus, of London, a Corresponding Fellow of the Academy. He first gave a historical sketch of the study of cerebral syphilis, our knowledge of which, he said, was of very recent origin, in the course of this paying special tributes to the labors of Virchow, Hübner, and Fournier. He then went on to say that the time at his disposal would only permit him to refer to two points in which comparatively little had as yet been ascertained. These were syphilitic coma and syphilitic hemiplegia.

SYPHILITIC COMA.

Coma suddenly developing in a patient who has been suffering from venereal disease more or less recently, was a thing not generally known by the profession. The other forms of coma, which he enumerated, were well recognized, but syphilitic coma was not even mentioned in the text-books, Fournier being about the only author who referred to it. Dr. Althaus, altogether, had met with eight unmistakable cases, and they were all in males, between the ages of twenty and forty. In one case the coma came on only eight months after the contraction of the primary sore; in six the period varied from three to five years; and in one it was developed after an interval (from the initial lesion) of no less than seventeen years.

Among the exciting causes of syphilitic coma, may be mentioned over-work, mental anxiety, sexual excess, and alcoholic excess. In two out of the eight cases referred to, no exciting cause could be ascertained.

In describing the symptoms, he mentioned first the premonitory, and among these were headache, confusion of ideas, and drowsiness, defective vision, with the appearance of black spots before the eyes, numbness in the limbs, and more or less loss of muscular power.

Next, he spoke of the symptoms of the initial stage. Habitually, the coma comes on during sleep, and the patient is discovered in the morning lying quietly on his face. He evidently suffers no pain, and there is no restlessness or tossing of the body. The countenance is utterly devoid of expression, and is generally pale. Sometimes the patient can be partially aroused. If so, he will complain that he is blind, and on opening the lids, it will be found that the eye-balls are deeply contracted within the orbit. There is also divergent strabismus, the degree of which depends on the intensity of the coma. The pupils are contracted, and the reflex sensibility of the conjunctiva abolished. There is relaxation of all the muscles, and the limbs on both sides are affected alike. There is more or less anæsthesia, and the tendon reflexes are either diminished or entirely abolished. There is also incontinence of the excretions, from paralysis of the sphincters. The urine dribbles away, but, as a rule, the bowels are very constipated. If they are opened by purgative medicine, however, their contents are passed involuntarily. The pulse is generally slow — 40, 50, or 60. In one case it was as low as 36, but in another it was 86. Its quality is variable. The respiration is slow and shallow, the average frequency being eight to ten a minute. The temperature is below normal (96° to 97°), and in one case was as low as 95°. In one case there was extensive herpes of the face, but, as a rule, the skin was dry and parched. The tongue is also dry, and deglutition difficult.

Such being the symptoms present, what is the condition of the brain giving rise to them? There are unmistakable signs of paralysis, but there are also signs of irritation. Such a coincidence, however, is by no means so singular as might at first appear. The brain is an exceedingly complex organ, and the gray cortex requires a larger supply of oxygenated blood than any other part. In poisoning by carbonic acid, there is first a stage of irritation, and then this is fol-

lowed by coma. In syphilitic coma there is also probably a short stage of irritation. The initial stage lasts from two to five days, when recovery begins, or the patient sinks into the final stage. In ten days or a fortnight he may apparently be well, and may be able to resume his usual occupations. In other cases, however, recovery is more gradual.

FINAL STAGE.

If the progress of the case is towards a fatal termination, there is an intensification of the symptoms of loss of voluntary muscular power and reflex sensibility. The lower jaw drops, and the mouth lies wide open. The breath is fetid, and the power of swallowing is lost. The surface of the body is bathed in a clammy sweat, and the pulse is small, full, and very quick. It rises to 180, and later, it is impossible to count it. The sphygmographic tracing is that of a patient in collapse. The respiration grows more and more rapid, and may be of the Cheyne-Stokes character. Hypostatic pneumonia is also likely to result. This stage lasts from twenty-four to thirty-six hours.

Of the eight cases seen by Dr. Althaus, six ended in recovery and two in death, in the first attack. In three of the six which recovered from the first attack, there was a relapse. One of the patients recently died, after having had no less than five attacks of syphilitic coma. No autopsies, unfortunately, were permitted in the cases which proved fatal.

Dr. Althaus expressed the opinion that this affection is due to implication of an important cerebral artery, and in all probability the basilar, which supplies the most important vital parts of the brain. Sudden occlusion of this artery causes death by profound coma, as has been proved by a number of instances. He described a case in one of the London hospitals, in which the autopsy showed that there was an occlusion of the artery, due to inflammatory action, and also referred to similar instances reported by Vulpian, Bastian, and other authorities. By occlusion of the basilar artery, sudden anæmia of the cardiac and respiratory centres is caused, but in syphilitic occlusion the case is usually of longer duration than in ordinary thrombosis. This explanation of the pathology of syphilitic coma, Dr. Althaus remarked, is still in need of confirmation by post-mortem observation.

The diagnosis, he went on to say, is easy or difficult, according to circumstances. Apoplexy usually occurs in the old, while syphilitic coma is seen in the prime of life, and apoplexy is attended with hemiplegia, which is lacking in the latter. The variety of apoplexy which it most resembles is that in which the hæmorrhage takes place into the pons. It may be mistaken for opium poisoning, but in syphilitic coma the pupils are not so extremely contracted as in other opium poisoning or hæmorrhage into the pons. If itching of the skin and retention of urine are also present, it will indicate opium poisoning. The fits in epilepsy, hystero-epilepsy, etc., are of much shorter duration than an attack of syphilitic coma, and are also apt to be accompanied by biting of the tongue, foaming at the mouth, and perhaps petechiæ of the face. In suspected alcoholic coma, the odor of the breath is not a reliable sign, as alcoholic stimulus may have been administered at the onset of an attack of coma due to other causes; but if the urine is found to contain alcohol, the diagnosis will be plain, since this agent, if taken in large quantities, is eliminated unchanged in the urine. The temperature is usually lowered in alcoholic coma, but not to as marked an extent as in syphilitic coma.

The detection of uræmic coma is easy if the history of the case is known. It may come on suddenly, but it is usually preceded by headache and nausea. It is characterized by fits and remissions; not the dead level of unconsciousness which is met with in syphilitic coma. Anasarca is often present, and the examination of the urine will reveal the presence of disease of the kidneys. By raising a blister and examining the serum which it contains, the presence of urea can also be detected in the blood. One half of the cases of diabetes terminate in coma, and therefore the condition of diabetic coma, or acetonæmia, is not infrequently met with. The peculiar difficulty ot respiration and the acetone breath are important factors in the detection of diabetic coma, and the urine will also usually be found to contain acetone and its allies.

As to the prognosis, this is always grave, although not so hopeless as is the case of either uræmic or diabetic coma. It is serious, however, because the presence of this condition shows that the syphilitic disease has invaded the cerebral centres. Even if the patient recovers from the immediate attack, there is always danger of a return of the trouble. The prognosis of the attack itself is usually hopeful; but active treatment is required, and the future prognosis also depends to a large extent on this. If the patient is willing to submit to a two years' course of systematic treatment, he will probably have a fair chance of recovery; but if he will not carry out its details thoroughly, the alternative is death or general paresis. The two fatal cases which Dr. Althaus met with were hopeless when he first saw them, as they were far advanced, and had been treated simply with stimulus.

In speaking of the treatment he said that ether by hypodermic injection was often of great service; the usual dose being twenty minims three or four times a day. Ammonia is of little value, but blistering sometimes has a good effect; while the cold douche, applications of ice, etc., are likely to do more harm than good. The great reliance must be specific treatment, and the best method of employing it so by means of inunctions. There is perhaps nothing so good for this purpose as the old blue ointment; though the oleate of mercury, made with the yellow oxide, is excellent too. Lanolin can also be used with good effect as a vehicle for the mercury. For hypodermic use the perchloride is the best preparation, and the injections should be made deep into the gluteal muscles in order to avoid as much as possible the danger of abscesses.

Dr. Althaus then took up the subject of

SYPHILITIC HEMIPLEGIA,

of which he said there was a number of different types, although they all have certain points in common. In the first place, syphilitic hemiplegia almost invariably occurs in males (ninety-five per cent. of all cases); secondly it occurs in the young, (between the ages of eighteen and forty); and, third, it is characterized by the peculiar behavior of the deep reflex phenomena. The complication of hemiplegia with ocular paralysis of different kinds is very significant of syphilitic disease. He related a case in which the patient, twenty-eight years of age, had incomplete paralysis of the left side, which had been incomplete from the begin-

ning, and which was preceded by ptosis. There was no apoplectic seizure at the time of the onset of the trouble.

Another type was preceded by headache of peculiar obstinacy, which disappeared, however, when the hemiplegia set in. In another variety both sides are affected, but at different times. In some cases many months intervene before the hemiplegia occurs on the second side. In still another variety the paralysis comes on, not more or less rapidly, but slowly. In one case which he related, hemiplegia developed within eight months after the initial lesion of syphilis. The patient was systematically treated, and made a fair recovery.

These different types were all totally different from ordinary hemiplegia. All cases of the latter were very much alike; but scarcely any two cases of syphilitic hemiplegia resembled each other. The diagnosis of this affection by the test of treatment was often very fallacious, for many cases of syphilitic hemiplegia were not materially benefited by specific treatment. There was, however, one truly pathognomonic symptom, namely an excessive exaggeration of the deep tendon reflexes, both of the upper and lower extremities. This was the symptom on which Dr. Althaus depended in making the diagnosis. It could only be relied upon, however, in cases in which the reflexes on one side were normal.

The treatment was not always satisfactory, and therefore in such cases the prognosis was not good. Some cases unfortunately terminated in general paralysis of the insane. It was the secondary consequences of the syphilitic process which often proved unamenable to treatment; for the removal of the syphilitic gumma would not restore the nerve-cells and fibres which had already been destroyed. The lesson to be derived from these cases was, therefore, that active treatment should be commenced as soon as there is the slightest evidence of cerebral trouble. The secondary ordinary lesions which result from syphilitic lesions of the brain are unfortunately not affected by anti-syphilitic treatment.

DISCUSSION.

Dr. R. W. Amidon said that he would like to call attention to one factor in the production of syphilitic coma which the learned author of the paper had not specifically alluded to, namely, the factor of a weak heart. Dr. Althaus, he felt sure, however, would be willing to acknowledge its agency, since he had mentioned among the exciting causes over-exertion, anxiety, and sexual and alcoholic excesses; all of which conditions were recognized as conducing to a weak heart. He thought that this important factor did not receive sufficient attention from the profession.

The occluding disease of arteries was well understood, but alone, he did not think it was sufficient to account for the coma. Taken in connection with a weak heart, however, it would satisfactorily account for all the phenomena so graphically described in this paper.

Dr. A. D. Rockwell remarked that as our experience in the domain of nervous diseases widens, we must necessarily become more and more impressed with the importance of syphilis in this connection. Patients often state, with honest conviction, that they have never had syphilitic trouble, and yet the subsequent history of their cases proves conclusively that they have. He said he had had no personal experience with syphilitic coma, but he thought that perhaps a case which he had had under his care some time ago might prove of interest in connection with the subject of the paper. It was one of spastic paresis, with some difficulty of utterance. From the beginning there had been facial paralysis. This had been followed by aphasia and hemiplegia, which afterwards disappeared, and then reappeared again. The patient denied that he had ever had syphilis, but a course of anti-syphilitic treatment resulted in very marked benefit.

Dr. Robert W. Taylor said that he was in hearty accord with the author of the paper in much that he had said, but he thought that he had scarcely done full justice to certain observers in the historical part of it. It was true that two great pathological epochs in connection with syphilis were inaugurated by Virchow and Hübner, but these were outshone, he believed, by certain clinical epochs. The Strasbourg thesis of Hildebrand showed that about 1848 and 1850, there was some professor at that university who had taught a knowledge of cerebral syphilis. The next epoch commenced about 1863, with the writings of Lancereaux and other brilliant French syphilographers, and these were the text-books from which a vast amount of our knowledge had been derived. Without detracting from the labors of Hübner, he thought that a word of recognition was due to the late Walter Moxon, of London, for his remarkable contributions on syphilitic disease of the arteries, published in "Guy's Hospital Reports."

Dr. Althaus's description of syphilitic coma was clear, graphic, and admirable in every way, and it was evidently the result of careful bedside study. As regards syphilitic hemiplegia, Drs. Van Buren and Keyes, in this country, had studied the subject very thoroughly, and all the varieties and symptoms described by Dr. Althaus had been noted in the paper which Dr. Keyes read a number of years ago, embodying their researches, the main points of which had now been incorporated in several text-books. He believed that certain concomitants, besides syphilis, were necessary to produce these severe neuroses, and among them he would rank as of great importance alcoholic and sexual excesses, and unnatural sexual habits.

Dr. Landen Carter Gray, of Brooklyn, said that some of the questions brought up by the author of the paper, he thought, ought to receive a little discussion. The pathology of these cases of syphilitic coma was a subject which still deserved a great deal of study, and personally, he was hardly prepared to accept Dr. Althaus's conclusions. The textural changes which took place in the brain itself were out of all proportion to the arterial changes, as was shown in two autopsies which he had had the opportunity of seeing, in cases where the coma was the predominant symptom before death, the paralysis present being secondary. In both cases, the presence of arterial disease was evident not only to microscopic inspection, but also to the naked eye. Yet this, so far as he was able to judge, was not sufficient to account for the symptoms noted during life. In one of the cases there were enormous textural changes, including softening, amounting to pulpiness, with lepto-meningitis and syphilitic neoplasms. The mere theory of some occlusion of the basilar artery, he thought, was not enough to account for the coma. Again, if the coma were very profound, it might be impossible to say whether any paralysis were present or not.

As to the matter of treatment, he was somewhat surprised to hear the views expressed in the paper. Dr. Althaus apparently depended entirely on mercurials, and had little or nothing to say in regard to iodide of potassium. As for his part, he had some time since given up the use of mercury entirely in these cases, as he had never seen any beneficial results from it. He had had indubitable evidence, in his experience, of the superior value of the iodide, and he believed that this was the experience also of the great majority of neurologists in this country.

Dr. L. Putzel said that he was glad that the question of therapeutics had been taken up, and stated that he agreed entirely with the author of the paper in regard to the superiority of mercury. It was now about six years since he had become convinced that syphilis did not yield, or at least, but slowly, to iodide of potassium. Formerly, he employed the bichloride of mercury, but more recently he had found much better results from the use of inunction. It was his custom to employ this until the teeth began to be touched, and then discontinue it. In connection with this, small doses of iodide of potassium sometimes seemed of service.

As to occlusion of the basilar artery, which Dr. Althaus would assign as the direct cause of syphilitic coma, it seemed to him that we were likely to have a number of vessels injured, but not sufficiently to cause occlusion. The blood-supply would be diminished, but this would not be sufficient to cause total occlusion until the end.

Recent Literature.

Rheumatism, its Nature, its Pathology, and its Successful Treatment. By T. J. Maclagan, M.D. New York: Wm. Wood & Co. 1886.

This volume, which constitutes the September issue for the present year of "Wood's Library of Standard Medical Authors," is a reprint of the English edition, which has already received favorable notice in these columns. Its publication as one of the series referred to will be gratifying and profitable to the subscribers.

Diagnosis of Diseases of the Brain and of the Spinal Cord. By W. R. Gowers, M.D., F.R.C.P., Assist. Prof. of Clin. Med. in Univ. Coll., Phys. to Univ. Coll. Hosp., and to the Nat. Hosp., for the Paralyzed and Epileptic. New York: William Wood & Co. 1885.

This most valuable work comprises the lectures of the author on the diagnosis of diseases of the brain and spinal cord. The student or practitioner who studies it carefully, will be amply repaid by the clear ideas which he will attain regarding locality and nature of lesions affecting the central nervous system, and the methods of analyzing cases of nervous disease. The book is not a systematic treatise on the various lesions affecting the brain and cord, the sections on the pathology being rather intended to teach methods of diagnosis than to describe exhaustively the diseases diagnosticated. The student will acquire a practical knowledge, however, of the principal disorders with which he will have to deal in his practice. It is needless to call attention to separate parts of the work, as all are excellent, carefully prepared, and presented in a clear, concise, and attractive style. The book contains about three hundred pages.

A Guide to the Examination of the Nose. By E. Cresswell Baber, M.B., London. Surgeon to the Brighton and Sussex Throat and Ear Dispensary. With illustrations. New York: J. H. Vail & Co., 21 Astor Place. 1886.

This book has been carefully prepared, and it can be recommended as a reliable guide to the examination of the parts of which it treats. The author has wisely drawn largely from Zuckerkandl's classic work, which gives peculiar value to the chapter on the anatomy of the nose. Attention is called to some important anatomical points which have not been sufficiently insisted upon, and familiar details are rapidly passed over. Considerable prominence is given to the tubercle of the septum, an accumulation of glandular elements forming a distinct eminence on either side of the septum in its superior region, and which Mr. Baber is inclined to think guards and protects the anterior extremity of the olfactory slit in the same manner that the anterior end of the inferior turbinated bone, especially when erected, guards the respiratory region.

The chapters on anterior and posterior rhinoscopy describe clearly and in detail the different instruments and methods necessary to examine the nasal cavities. The book is profusely illustrated, and contains many original drawings by the author.

Dictionary of Practical Surgery by various British Hospital Surgeons. Edited by Christopher Heath, F.R.C.S., Holme Professor of Clinical Surgery in University College, London; and Surgeon to University College Hospital. Philadelphia: J. B. Lippincott & Co. 1886. 2 vols. in 1, 8vo., pp. vi, 970 and 884.

The dictionary is intended to fill a want in the library of the busy practitioner by supplying immediate information as to diagnosis and treatment in cases of surgical disease or injury. The aim of the editor has been to produce a compendium of the British practice of surgery at the present day, and he considers that the object has been fairly accomplished, as only two years have elapsed between the planning and completion of the dictionary. In the general plan of the book the different surgical affections are described in comparatively short articles under their proper names, in alphabetical order, or when it has been found more convenient to group together a series of diseases of one organ, cross references have been given.

The value of such a dictionary must depend very largely upon the character of the writers of the different articles, and the list contains the names of a very large number of men who are widely known in connection with the subjects upon which they have written.

Abdominal Aneurism is treated by William Murray, Abdominal Hernia by Frederic Treves, Abdominal Tumors by J. Knowlsey Thornton, The various Syphilitic Affections by Jonathan Hutchinson; Robert Liveing has written many of the Dermatological Articles, and Berkeley Hill that on Stricture of the Urethra; Tumors of the Bladder are treated by Sir Henry Thompson, Lithotomy and Lithotrity by William Cadge; William Watson Cheyne writes on Antiseptics, Dr. Cruise, of Dublin, on the Endoscope; Mr. Gamgee on various subjects connected with the treatment of wounds.

Other writers are Sir William MacCormac, William

Maccuen, Stephen MacKenzie, Howard Marsh, Sir James Paget, Bilton Pollard, C. Mansell Moullin, T. Pickering Pick, Victor Horsley, Charters J. Symonds, Bernard Pitts, Dyce Duckworth, Alban Doran, Percy Kidd, and many others whose names are a guarantee for the excellence of their papers.

One of the great advantages of such a book is the readiness with which one gains information in regard to unusual and obsolete terms, and some interesting articles are to be found, as that by Mr. Chetton on Fragilitas Ossium, and those on Riders bone, Dugas' test, and others too numerous to mention: the book contains also a description of a large number of splints and operations that are known by the names of their inventors, but the book shows that it is what it claims to be, a compendium of British Surgery, by the omission of some important American names, as Physic's splint.

The book covers the entire domain of surgery and many kindred subjects, and we can imagine might be especially useful to any one who does not pretend to maintain an accurate acquaintance with all the wide field, but is still constantly liable to meet, in reading and conversation, with terms newly come into use.

The writer of this notice must confess to have opened this book with a feeling that dictionaries were becoming too frequent, but a very little time spent in reading the articles that interested him, has served to impress him with the fact that a great deal of time and care has been spent in its preparation, and that it is well worthy of the place beside Quain's Dictionary of Medicine, which it was intended to fill.

A Treatise on the Diseases of the Nervous System. By WILLIAM A. HAMMOND, M.D. Eighth edition, 8vo., 945 pp. New York: D. Appleton & Co. 1886.

This edition has been "revised thoroughly," but it does not differ materially from the preceding edition except in the addition of a section on "Certain Obcure Diseases of the Nervous System." This section consists of chapters on tetany, Thomsen's disease, and the curious disturbance known as miryachit, with its kindred affections. The first two chapters are exceedingly defective. No mention is made of the peculiar position of the fingers in the spasm of tetany, nor of Trousseau's symptom — the aggravation of the spasm by pressure on the nerve trunks. The electrical reactions in the two diseases, so fully described by Erb, are also neglected. The chapter on miryachit is curious and entertaining. The revisions of later editions, however, have failed to make the book an exponent of recent knowledge. Its value to the specialist and the general practitioner is apparent when we state that there is no discussion of tendon reflex or reaction of degeneration, no chapter on multiple neuritis, and no description of the different forms of peripheral paralysis; and, furthermore, that under aphasia no mention is made of Kussmaul's investigations or of word-deafness; under amyotrophic lateral sclerosis no mention is made of exaggeration of the reflexes; under infantile paralysis no mention is made of qualitative changes in electrical excitability; and under locomotor ataxia no mention is made of reflex immobility of the pupils to light. Yet this book "has continued to receive approval, at home and abroad, to an extent beyond that ever given to any other work of like scope and objects, published in any part of the world"!

Medical and Surgical Journal.

THURSDAY, OCTOBER 21, 1886.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., *Boston. Price, 15 cents a number; $5.00 a year, including postage, to subscribers in the United States and Canadas. Foreign subscribers are charged the postage in addition.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.

CUPPLES, UPHAM & COMPANY,
283 WASHINGTON STREET, BOSTON, MASS.

THE FORTY-FOURTH MASSACHUSETTS REGISTRATION REPORT.[1]

THE population of Massachusetts, by the State Census of 1885, was 1,942,141, of whom 932,884 were males and 1,009,257 were females. The population of the State increased 30.37 per cent. from 1865 to 1875 and 17.57 per cent. from 1875 to 1885.

The birth-rate in 1885 was 25.12 per 1,000 of the population; the death-rate 19.61. Since 1860 the excess of birth-rates over death-rates, calculated by periods of five years, has gradually diminished so as to be now about one-half what it was twenty-five years ago.

There were 50,379 births during the year, including 1,589 still-born. The rate of living births (48,790) to the population is nearly the same as that of France, as is the average for the last twenty years, but much less than in England, Denmark, Sweden, Austria, Netherlands, Hungary, Switzerland, Italy, Spain and Germany. In the twenty-three cities in Massachusetts the birth-rate in 1885 was 27.59; in the rest of the State 21.97. There were 903 illegitimate births.

The marriage-rate was 8.78 (17.56 persons married to each 1,000 of the population) or 1.5 lower than the average of the past twenty years. The approximate average age at marriage was of men 28.05 years; of women 25.30. There were 646 divorces granted during the year, 214 to men and 432 to women.

The deaths, 38,094, were 1,104 more than the previous year, making a death-rate of 19.61, as compared with 19.80 for the period of five years, and 19.44 for the thirty years, ending in 1885. In the twenty-three cities, with a population of 1,087,496, the death-rate was 21.2; in the rest of the State 17.6. For the four quarters of the year the percentages of all deaths were, beginning with the first 24.4; 23.0; 29.1; 23.5.

[1] Forty-Fourth Report to the Legislature of Massachusetts relating to the Registry and Return of Births, Marriages and Deaths in the Commonwealth, for the Year ending December 31, 1885. Together with the Reports relating to the Returns of Libels for Divorce and to the Returns of Deaths investigated by the Medical Examiners. For the Year 1885. Prepared by the Secretary of the Commonwealth. With Editorial Remarks by Frank Wells, M.D.

The death-rate of males was 20.2; of females 19.0. Thirty-one + (31.41) per cent. of the deaths were of children under five years of age; 20.03 of infants under one year. The death-rates at the several ages were, under 1, 212.49; under 5, 67.00; 5 to 10, 7.46; 10 to 15, 3.77; 15 to 20, 6.35; 20 to 30, 9.08; 30 to 40, 10.62; 40 to 50, 12.96; 50 to 60, 19.71; 60 to 70, 36.19; 70 to 80, 76.16; 80 and over, 182.32.

The percentage of deaths from the "zymotic" diseases was 4.6 less than the average of the past ten years and less than in any one of the ten; from constitutional diseases, .5 less than the average, but from "local" diseases 5.5 above the mean for ten years. The relative prevalence of the prominent "zymotic" diseases is as follows:

Years.	Diseases.									
	Dysentery.	Typhoid Fever.	Whooping Cough.	Croup.	Diphtheria.	Measles.	Scarlatina.	Cholera Infantum.	Small-pox.	Total.
1876,	417	881	192	684	2,610	47	1,222	2,087	31	8,171
1877,	580	814	369	544	2,634	135	467	1,827	26	7,496
1878,	602	679	400	583	1,934	305	404	1,573	2	6,482
1879,	372	637	302	559	1,734	19	850	1,349	8	5,830
1880,	395	882	230	625	1,769	236	574	2,118	38	6,867
1881,	360	1,072	217	677	1,706	230	397	1,861	47	6,567
1882,	398	1,079	265	491	1,280	68	318	2,159	45	6,103
1883,	336	860	137	530	1,091	321	575	1,941	5	5,796
1884,	254	875	410	562	1,084	75	627	2,081	3	5,971
1885,	253	768	184	520	1,003	313	587	1,852	19	5,499

Of constitutional diseases, pulmonary consumption caused 5,955 deaths in 1885, as compared with 5,798 in 1884, 5,931 in 1883, 5,865 in 1882, 5,886 in 1881, and 5,494 in 1880. From cancer, the number of deaths was 1,087 in the past year, as against 1,060 1,027, 987, 949, 982, 862, 807, 647, 657 and 593 in the previous ten years.

Of "local" diseases, apoplexy, paralysis, insanity and convulsions, have steadily advanced in fatality since 1876 — the number of deaths from these diseases, in 1885, having been respectively, 294, 151, 40 and 60 greater than the average for ten years. From pneumonia, the number of deaths exceeded those for 1884 by 822, and the average for ten years by 731; from bronchitis, 192 more deaths took place than in the previous year; from pleurisy the mortality was 73 greater than in 1884. Heart diseases and Bright's disease were more fatal than usual.

For the ten years previous to 1885, there was a very uniform yearly decrease in the mortality from childbirth. The past year, however, exhibits a sudden increase in the number of deaths from this cause — 83 more than in 1884.

The following very striking table, even after due allowance for greater accuracy in statistics of late years, shows an extraordinary result of the strain of modern life, as well as of improved sanitation, by virtue of which there is a lessened mortality from infection-diseases, which prevail in early or middle life, and a correspondingly increased death-roll from the diseases which belong to middle and late life.

	Death-Rates.					
	1860.	1865.	1870.	1875.	1880.	1885.
Mortality-rates per 10,000 from Apoplexy. . .	1·93	2·08	2·70	2·78	4·19	5·12
Softening of the Brain .	·36	·33	·58	·59	·68	·65
Paralysis	3·26	3·78	4·32	5·43	5·23	5·82
Insanity.	·58	·59	·71	·71	·71	·96
Cephalitis and Brain Disorders	5·93	7·61	6·04	6·91	6·19	7·46
Totals, ...	12·06	14·39	14·95	16·42	17·00	20·05

At the end of the report are two tables of statistics, giving a compilation of the work done by the medical examiners of Massachusetts during the year 1885, based upon returns made by the examiners, in accordance with the requirements of a law enacted in 1884 — clearly the work of clerks skilled in making statistical exhibits. It was hoped that these records, collated, edited and published, would stimulate medical examiners to the performance of the best work possible, and would incidentally afford valuable and useful material for medico-legal study. The tables alone show inadequately the results of the work done by the medical examiners and their manner of doing it. We trust that the next Registration Report will contain an elaborate analysis and editorial comments on these tables and bring out their full value.

The report, in general, is a creditable one to the editor, but there are many ways in which it may be improved, and we have always taken the ground that the editing of the vital statistics of the Commonwealth should be in the hands of the State Board of Health, where it was at the time of the death of the former board. The medical profession would then have great cause for congratulation in the matter, with so painstaking a statistician as Dr. Abbott and such accomplished sanitarians as Dr. Walcott and Dr. Draper, and all the resources of their office, to supplement the work of the Secretary of State, who already deserves the thanks of all interested in public health for the ability and zeal with which he has yearly improved his part of the work, namely, the collection and compilation of the statistical returns.

TUBERCULOSIS OF THE THYROID GLAND.

Virchow formerly held this affection as a very rare one, and as extending from the neighboring lymph-glands. Subsequently, Cohnheim regarded it as a constant accompaniment of the acute general form, while Chiari has found it in the course of chronic disease, and holds the tubercles to originate from the interstitial tissue, rather than from the midst of the alveolar epithelium.

E. Frankel[1] has more lately made observations on six cases occurring in fifty cases of phthisis, out of three hundred and seventy autopsies. His results

[1] E. Frankel. Virchow's Archiv., Vol 104, p. 58.

agree in the main with the two authors last mentioned. First, as to the gross appearances. There is no doubt that the miliary is the most common form. In the extent of the disease, there are great variations; at times the whole gland is equally involved, at times one lobe only is the seat of trouble. In the marked cases, after the surrounding soft parts have been removed, grayish-white nodules can be seen shining through the proper capsule, and, on section, stand out in the same way from the midst of the tissue in which they lie. In other respects, as a rule, the organ presents no other variation, nor is it increased in size. Virchow has reported a case with cheesy and softened nodules, and Frankel has met with another.

It was hoped to settle the question as to which of the elements of the thyroid could be looked upon as the point from which the tubercle took its departure. The tendency to early cheesy degeneration of these growths throws difficulties in the way, but from a large series of microscopic preparations, it was evident that their origin is in the soft interstitial tissue separating the follicles. This is quickly broken through by abundant round cells, which are at first still separable from the lining epithelial cells. They soon mingle with these and with the other contents, until the different elements can no longer be distinguished by aid of the microscope. At times this tuberculous infiltration seems to act by compressing the follicles until their opposite walls come in contact. In this or that way, the normal structure of the gland disappears, and thus appear accumulations of round cells, undergoing more or less marked retrograde changes, and among which are found typical giant cells.

This observer is the first to demonstrate the presence of tubercle bacilli in the thyroid. Of his six cases, they were present in five. In one case only, however, were they present in great numbers; in the others, they were to be seen only here and there. His observations go to prove the correctness of Weigert's theory [2] in regard to the formation of giant-cells, namely, that where the bacilli are in small numbers, numerous giant-cells are found.

MEDICAL NOTES.

— The Noble County (Ind.) Medical Society receives $500.00 a year for caring for all the sick paupers in the county. The member nearest the pauper treats the same. The money is used for building up a society library.

— The *Medical Age* is responsible for the following: A gentleman received a note from his lawyer, which he was unable to decipher. On his way to his office, he met a friend at the door of a drug store. The friend, after vainly attempting to read the note, suggested that they step inside and hand it to the druggist, without comment. The druggist, after studying it in silence for a few minutes, stepped behind his prescription case, and in a short time returned with a bottle of medicine, duly labelled, and bearing directions. When the gentleman saw his lawyer, he was informed that the note was a notice for him to call at his office between 3 and 4, P. M., of the following day.

— Somebody, we believe it is Miss Kate Field, tells a story illustrative of one of the embarrassments attending cremation, to the following effect: A lady making a visit upon friends, found, to her great annoyance, that she had neglected to bring with her any tooth-powder — an article upon which she was very dependent for her comfort. Looking about her bedchamber, her eye fell upon a small, beautifully-wrought vase or jar. Removing the cover, she found it to contain a grayish, calcareous powder, which, to her mind, was evidently designed for use as a dentifrice. She did not hesitate to avail herself of the lucky discovery, the use of which proved most satisfactory. The next day she apologized to her hostess for having made free with the toilet appliances of the room, and at the same time remarking that the article she had found was much more effective for its purpose than anything she had hitherto used, desired to know where it could be obtained. The countenances of the family assumed an expression, at first, of bewilderment, which deepened into one of consternation as one of the daughters gasped forth, "Why, that's aunty!"

NEW YORK.

— Dr. Fordyce Barker gave a large reception at his residence, on the 15th of October, to Professor Winckel, of Munich, and the members of the New York Obstetrical Society.

— The widow of the late Mr. Woerishoffer, the banker, has given the sum of one hundred thousand dollars to different scientific and charitable objects, as a memorial of her husband, and it has just been announced that twenty-five thousand of this amount is to be presented to the New York Academy of Medicine, through the President, Dr. A. Jacobi.

— The opening and dedication of a new German hospital — the Lodge and Association Hospital — took place October 10th. It was the result of the organization not long since of a society entitled the Aid Society of the Lodge and Association Hospital, by the representatives of a number of German lodges and societies, for the purpose of raising a fund for the fitting up and maintenance of a hospital for the benefit of sick members of the various bodies to which they belonged. A suitable building was rented on St. Mark's Place, and about $3,000 expended in arranging it for the purpose designed. It has accommodations for about forty patients, and is to be under the direction of Dr. Emil Neumer, physician-in-chief. There will be fourteen sub-physicians, and members of participating lodges and societies will be admitted under all circumstances, except when suffering from contagious diseases. The patients will all have the privilege of selecting their own physicians, and may remain in the hospital as long as one year, if necessary. The Secretary has issued a

[2] Boston Medical and Surgical Journal, Vol. 113, p. 465.

circular requesting associations and societies of every kind to participate in the enterprise, and stating that the annual dues have been fixed at a minimum of $15, payable in advance, any society contributing receiving the benefits of the institution from the day the dues are paid.

Miscellany.

OLEUM EUCALYPTI IN MALARIAL AFFECTIONS.

Dr. Musser, of Philadelphia, records in the *Therapeutic Gazette*, June, 1886, a series of experiments with this oil in the treatment of various forms of malarial fever. He gives ten drops on a lump of sugar three or four times daily to adults, but states that three or five drops repeated oftener would be of more service. He says, "The oil of eucalyptus is of material value in malarial affections, and in cases where quinine is, on account of idiosyncrasy, inadmissible, the drug may be relied on in nearly one-third of all the cases of vague malarial intermittent affections." He concludes thus: — "1. That the oil of eucalyptus is of decided value in about thirty-three and one-third per cent. in all cases of intermitting malarial fever. 2. That it has no specific value in any one type of the disease. 3. That the longer the duration of the disease the less liable is it to do good. 4. That relapses are not prevented by it. 5. That its influence on the spleen has not been demonstrated. 6. That a dose of ten drops four times daily has been a sufficient dose, but that five drops every three hours would be of greater value possibly. 7. That good results are not attained as quickly as by large doses of quinine, but that a good effect should be observed within five days at least."

DR. CHARLES DUDLEY HOMANS.

At a meeting of the Obstetrical Society of Boston, held October 9, 1886, the President said:

"It becomes my sad duty to remind you at this meeting that Dr. Charles Dudley Homans, an original and valued member of this Society, died at Mt. Desert, his summer residence, on the second day of September last. We shall greatly miss his genial presence and manly bearing. Our profession has lost in him an honorable and straightforward member, one whose high sense of honor and sound judgment made him a valued friend and adviser. These characteristics of our departed associate were ever apparent, and attracted all men to him.

"I need not remind you of the many offices of responsibility which he held during his useful and unostentatious life. He loved his profession and was jealous of its purity. He was always a source of strength in this Society and filled at one time and another nearly all its offices.

"'Life's race well run,
Life's work well done,
Life's crown well won,
Now comes rest.'"

The President then appointed Drs. William Ingalls, W. W. Wellington, and C. Ellery Stedman a committee to draft a suitable minute for the records. The committee reported as follows:

"On the second day of September last this Society lost by death one of its original and most valued members, Charles Dudley Homans. His grand characteristic was loyalty: his duties at the hospital were never slighted: Societies, patients, friends, always knew where to find him. He had a clear and quick perception of statements, and was ready with wise advice, and truthfulness governed his speech. He was a good scholar, and had a tenacious memory: his disposition was cheerful.

"The Society desires to record this memento as an affectionate tribute to his memory."

The minute was unanimously accepted.

Charles M. Green, *Recording Secretary.*

BOSTON DISPENSARY.

The statistics of this institution for the year ending September 30, 1886, are as follows:

The number of new patients treated at the central office is 18,506, classified as follows: —

Medical Department.— Men, 2,453; women, 4,555; children, 2,188; total, 9,196.

Surgical Department.— men, 1,370; women, 656; children, 683; total, 2,709.

Skin Department.— Men, 534; women, 336; children, 312; total, 1,182.

Department for Diseases of the Nervous System.— Men, 339; women, 235; children, 51; total, 625.

Department for Diseases of Women. — Women, 426.

Department for Diseases of the Throat and Nose. — Men, 457; women, 562; children, 399; total, 1,418.

Department for Diseases of the Eye. — Men, 82; women, 152; children, 153; total, 387.

Department for Diseases of the Ear. — Men, 102; women, 147; children, 163; total, 412.

Department for Diseases of the Genito-Urinary System. — Men, 619; women, 5; children 2; total, 676.

Department for Diseases of the Rectum and Anus. — Men, 74; women, 29; children, 5; total, 108.

Orthopedic Department. — Men, 9; women, 10; children, 33; total, 52.

Dental Department. — Men, 300; women, 420; children, 685; total, 1,405.

The number of visits made by patients, old and new, at the Central Office is 36,956, classified as follows:— Medical, 15,440; surgical, 21,516; total, 36,956. The number of patients treated in the Districts is 11,576, including 279 cases of midwifery, classified as follows: men, 2,062; women, 4,311; children, 5,203; total, 11,576. The results of treatment in the Districts are as follows:

Discharged, cured or relieved	10,470
Removed to Hospitals	840
Died	296
Remaining under treatment	51
	11,657
Under treatment at last annual report	81
	11,576
The number of patients treated at the Central Office and in the Districts is	30,172

Number of cases of midwifery attended during the year	279
Number of cases of midwifery attended since July, 1856	4,724
Whole number of patients since October, 1796	931,344
Whole number of patients since July, 1856,	812,541
Average daily attendance at Central Office	123
Largest number present any one day, April 26	224
Smallest number present any one day, January 28	40
Number of recipes put up at Central Office during the year	42,210
Number of house recipes	34,221
Number of district recipes	7,989
Largest number of recipes put up in one day, May 17	251
Smallest number of recipes put up in one day, January 28	41
Number of paid recipes	38,747
Number of free recipes	3,463
Number of paid dental patients	900
Number of free dental patients	505

The list of medical officers is as follows: —

Surgeons: Drs. Charles E. Inches, J. Foster Bush, George N. Monks, Edward O. Otis. Physicians: Drs. Robert Disbrow, Joseph P. Oliver, John Dixwell, Thomas M. Rotch, Claudius M. Jones, Henry C. Haven, Harold Williams, James J. Minot, George M. Garland, Edward M. Buckingham, Vincent Y. Bowditch, William C. Emerson, Robert B. Dixon, Frederick W. Vogel, Russell Sturgis, Rufus A. Kingman, Thomas F. Sherman, James S. Howe.

Department for Diseases of the Skin.— Physicians: Drs. Francis B. Greenough, Abner Post. Department for Diseases of the Nervous System. — Physicians: Drs. William N. Bullard, Philip C. Knapp. Department for Diseases of Women. — Physicians: Drs. Francis H. Davenport, John W. Elliot, John B. Swift, George G. Hayward. Department for Diseases of the Throat and Nose. — Physicians: Drs. Thomas A. DeBlois, John W. Farlow, Edward W. Warren. Department for Diseases of the Eye. — Physicians: Drs. William D. Hall. Department for Diseases of Ear.— Physicians: Drs. Franklin H. Hooper, George A. Leland. Department for Diseases of the Genito-Urinary System. — Physicians: Drs. George H. Tilden, Francis H. Watson, Hayward W. Cushing, Gardner W. Allen. Department for Diseases of the Rectum and Anus. — Physicians: Drs. Walter J. Otis, William D. Hodges.

Obstetrical Department. — Physician: Dr. Charles M. Green.

Orthopedic Department.— Physicians: Drs. Royal Whitman, William M. Conant.

Dental Department. — Dentist: Dr. Joseph E. Waitt.

District Physicians: No. 1. Dr. Willis B. McMichael. No. 2. Dr. Herbert B. Whitney. No. 3. Dr. Frederic M. Briggs. No. 4. Dr. Edward Reynolds. No. 5. Dr. Howard M. Buck. No. 6. George E. Richards. No. 7. Dr. Thomas F. Temple. No. 8. Dr. Winfried B. Bancroft. No 9. Dr. Frederic W. Doggett.

Apothecary: Frederick H. Dudley. Assistant Apothecary: Joseph S. Lang.

WILLIAM H. H. HASTINGS, *Supt.*

Correspondence.

HOW TO ABORT A FELON?

WEST DENNIS, MASS., Oct. 10, 1886.

MR. EDITOR, — I have read recently, I think, in the columns of your JOURNAL, a formula for "how to abort a felon," the basis of which was flexible collodion.

I cannot find the formula now and cannot remember it. Will you or some one of your readers inform me through your paper, and oblige, yours respectfully,

H. S. KELLEY, JR.

PROFESSIONAL LETTERS OF RECOMMENDATION.

NEW YORK, Oct. 8, 1886.

MR. EDITOR, — Some years ago I gave a letter to a soidisant importer of "pure Hungarian wine," telling him that I had tasted the samples he had sent me, that I liked the taste and was glad to know where I could get a *vin de crû*, when needed in my practice.

To prevent unpleasant ethical complications, I called on the so-called importer and told him that my letter was intended solely for his personal use, and that under no conditions was it to be used as an advertisement of his wares to the general public. He professed to understand me perfectly, and said he would keep my letter as a valued one and put it with those of Longfellow, Salvini, Tanner the starver, and the late President Garfield's Doctor Bliss.

A few months ago the importer called on me, when I asked for proof that he was honest in his circular, when stating that his wines came directly to him from the vineyard. For, said I, the records of the New York Custom House fail to show that you have passed your wine as other importers pass what they bring from foreign ports. He told me that "a trade secret" which he would explain to me was the obstacle to having his name appear as those of Park & Tilford, John Duncan's Sons, and others appear on the entry book of the Custom House. He has never called to tell me the secret, nor has he explained (as he promised to do) why the late Doctor Frank H. Hamilton was mistaken in supposing that his name had been fraudulently used, as certifying to the excellence of the wines in question.

To-day, I was handed a trade circular sent by the importer (?) to a gentleman of this place, in which my name is added to the long list of those who have lauded the excellence and efficacy of those pure Hungarian wines.

Such conduct is dishonest, and I wish to let my medical friends know with what care they should deal with an imposter like the one referred to.

Yours respectfully,

JOHN T. METCALF, M.D.

THE REUNION OF SEVERED DIGITS.

BURDETT, N. Y., October 11th, 1886.

MR. EDITOR,— In your JOURNAL for October 7th, Dr. Souther reports a case of "Severed Digits Reunited."

As you ask for "any undoubted cases" I will give you one. In the early part of my professional career I was sent for to see a boy seven years old, who, the messenger said, had lost several fingers by a blow from an axe.

Being some distance from home I did not reach the patient till three or four hours after the accident occurred. I found that the first, second and third fingers had been completely severed. The wound was diagonal, beginning in the middle phalanx of the index finger near the second joint, and terminating in the last phalanx of the third finger near the root of the nail.

The direction of the wound left the bones of the several

stumps with pointed extremities, each stump being longest on the side looking towards the little finger.

To give the stumps a comely appearance as well as to facilitate the healing of the wound, these points of bone should be removed. Having no bone-forceps with me, I was trying to improvise a substitute, when the grandmother of the boy entered the room, bringing the lost fingers, saying:— "After we had made the boy as comfortable as possible, I thought I would go to the wood-pile and see if I could find the fingers. I fished them out of the snow, but it took a good while to find them all." (It was in the month of March and a deep snow had just fallen), she added "I don't suppose they will grow fast, but I want you to try to save them." I consented to make the trial, to gratify her, at the same time insisting that I did not think there was the slightest chance of success.

I carefully adjusted each finger to its stump, and secured them with bits of whalebone for splints, adhesive straps and bandages. I went the next morning fully expecting to remove the dead fingers and give the parts a proper dressing. Removing one of the bandages, I found the finger much too warm for a dead one, and, moreover, there were slight indications of returning circulation in the severed extremity. I readjusted the dressings to that finger, leaving the others undisturbed.

The fingers all united and restoration was perfect except that about half of the last phalanx of the index finger proved to be too distant to get a blood-supply, and was lost. Apparently there was no loss of function, the boy, in later years, used those fingers for writing and other things requiring skilful manipulation.

NELSON NIVISON, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 9, 1886.

Deaths reported 1,738: under five years of age 694: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 388, consumption 279, lung diseases 131, diarrhœal diseases 151, diphtheria and croup 107, typhoid fever 43, whooping-cough 137, malarial fevers 24, scarlet fever 12, cerebro-spinal meningitis nine, measles eight, puerperal fever two. From whooping-cough, New York and Brooklyn eight each, Pittsburgh five, Baltimore four, District of Columbia three, Boston two, Charleston and Lowell one each. From malarial fevers, Brooklyn seven, New York and Baltimore five each, Charleston four, District of Columbia two, Nashville one. From scarlet fever, New York four, Brooklyn and Pittsburgh three each, Boston and District of Columbia one each. From cerebro-spinal meningitis, New York and Fall River three each, District of Columbia, Nashville and Fitchburg one each. From measles, New York six, Boston and Pittsburgh one each. From puerperal fever, Boston and Haverhill one each.

In the 23 cities and greater towns of Massachusetts, with a population of 1,007,635 (population of the State 1,941,465), the total death-rate for the week was 20.28 against 21.71 and 21.50 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,083,817, for the week ending September 25th the death-rate was 21.0. Deaths reported 3,657: infants under one year of age 1 387; acute diseases of the respiratory organs (London) 154, diarrhœa 724, fever 65, scarlet fever 52, whooping-cough 37, measles 29, diphtheria 28.

The death-rates ranged from 16.0 in London to 43.7 in Norwich; Birmingham 19.7; Blackburn 25.9; Hull 25.9; Leeds 27.4; Leicester 20 6; Liverpool 27.5; Manchester 26.6; Nottingham 23.5; Portsmouth 31.8; Sheffield 28.4.

In Edinburgh 16.6; Glasgow 19.1; Dublin 24.7.

For the week ending September 25th, in the Swiss towns, there were 30 deaths from diarrhœal diseases, consumption 28, lung diseases seven, typhus two, whooping-cough, diphtheria and croup, one each.

The death-rates were: at Zurich 5.7; Geneva 12.1; Basle 19.2; Berne 12.8.

The meteorological record for week ending October 9, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps: —

Week ending Saturday, Oct. 9, 1886.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 9, 1886, TO OCTOBER 15, 1886.

EVERTS, EDWARD, first lieutenant and assistant surgeon. Ordered to proceed to Fort Grant, A. T., and there take station. S. O. 94, Department of Arizona, October 1, 1886.

FISHER, W. W. R., first lieutenant and assistant surgeon. Ordered, on the expiration of his leave of absence, to report to the commanding officer, Fort Bidwell, Cal., for duty as post-surgeon. S. O. 93, Department of California, October 4, 1886.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING OCTOBER 16, 1886.

WOOLVERTON, THEORON, surgeon. Detached from the United States Steamship "Shenandoah," proceed home and wait orders.

MEANS, V. C. B., assistant surgeon. Detached from the United States Steamship "Shenandoah," and ordered to Receiving Ship "Independence."

PARKER, J. B., surgeon. Detached from the United States Steamship "Swatara," proceed home and wait orders.

SHAFER, JOSEPH, assistant surgeon. Detached from the United States Steamship "Swatara," proceed home and wait orders.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE FOR THE WEEK ENDING OCTOBER 9, 1886.

BECKHAM, C. T., passed assistant surgeon. Granted leave of absence for thirty days, to take effect when relieved, October 5, 1886.

KALLOCH, P. C., passed assistant surgeon. Granted leave of absence for twenty-one days, to take effect when relieved, October 5, 1886.

PETTUS, W. J., assistant surgeon. To proceed to Evansville, Ind., for temporary duty, October 8, 1886.

KINYOUN, J. J., assistant surgeon. Appointed an assistant surgeon, October 4, 1886. Assigned to temporary duty at New York, October 5, 1886.

SOCIETY NOTICES.

The Annual Meeting of the Massachusetts Medical Benevolent Society will be held in Room B of the Harvard Medical College on Boylston Street, on the 28th of October, at half-past four o'clock in the afternoon. The Council will meet at four o'clock previous to the annual meeting.

ROBERT AMORY, M.D., *Secretary.*

NORFOLK DISTRICT MEDICAL SOCIETY. — A stated meeting will be held at Rockland Hall, 2343 Washington Street, Roxbury, on Tuesday, October 26th, at 2 o'clock, P.M. The Board of Censors will meet at 1 o'clock, P.M., for examination of candidates. Order of business: I. Reading of records. II. Reports from committees. III. Election of nominating committee. IV. Incidental business. V. Communications: (1) "Case of Typhoid Fever with Cerebral Complications," Harriet L. Harrington, M.D. The discussion will be opened by C. E. Stedman, M.D. (2) "A Case of Occlusion of the Upper Intestine," F. W. Vogel, M.D. (3) Exhibition of an Extempore Syringe-Pump and Aspirator, Edward T. Williams, M.D.

S. ALLEN POTTER, M.D., *Secretary.*

APPOINTMENT.

The Executive Committee of the International Medical Congress have appointed Dr. H. O. Marcy, of Boston, President of the Section (V) of the Congress for Gynecology.

BOOKS AND PAMPHLETS RECEIVED.

Sydenham and Hahnemann. By F. B. Stephenson, M.D., United States Navy. 1886. (Reprint.)

The Sanitary Condition of Harrisburg, (Pennsylvania.) By Hugh Hamilton, M.Sc., M.D. Harrisburg, Pa. 1886.

Announcement of the Regular Session of 1887 of the Hospital College of Medicine. Medical Department of Central University. Louisville, Ky. Wm. H. Bolling, M.D., President.

Annual Announcement of the Louisville College of Dentistry, Dental Department of Central University, Louisville, Ky., for the Regular Session of 1887. A. Wilkes Smith, M.D., D.D.S., Dean.

On Toxic Urine in Relation to Certain Surgical Operations on the Urinary Organs. By Reginald Harrison, F.R.C.S., Surgeon to the Liverpool Royal Infirmary, and Lecturer on Clinical Surgery in the Victoria University. (Reprint.)

How we treat Wounds To-Day. A Treatise on the Subject of Antiseptic Surgery which can be understood by beginners. By Robert T. Morris, M.D. Second Edition. New York and London: G. P. Putnam's Sons. 1886.

Diseases and their Commencement. Lectures to Trained Nurses, Delivered at the West London Hospital. By Donald W. Charles Hood, M.D., Cantab. Philadelphia: P. Blakiston, Son & Co. 1886.

Massage as a Mode of Treatment. By William Murrell, M.D., F.R.C.P., Lecturer on Pharmacology and Therapeutics at the Westminster Hospital, etc. Philadelphia: P. Blakiston, Son & Co. 1886.

A Laboratory Guide in Urinalysis and Toxicology. By R. A. Whitthaus, A.M., M.D., Professor of Chemistry and Physics in the Medical Department, University of New York, etc. New York: Wm. Wood & Co. 1886.

Action of the Trustees of the Boston City Hospital, upon the Petitions for the Introduction of Homœopathic Treatment and for the Admission of Medical Students to Surgical Operations and Clinical Instruction. Boston: Rockwell & Churchill. 1886.

The Physiological Action of the Heavy Oil of Wine. By Hobart Amory Hare, M.D. (Univ. of Pa.), Physician to the Children's Dispensary of the University Hospital and to St. Clement's Dispensary; Assistant in Physical Diagnosis in the University. (Reprint.)

Elements of the Comparative Anatomy of Vertebrates. Adapted from the German of Robert Wiedersheim, Professor of Anatomy in the University of Freiburg-in-Baden. By W. Newton Parker, Professor of Biology in the University College of South Wales and Monmouthshire. With additions by the author and translator. 270 woodcuts. London: Macmillan & Co. 1886.

UNITED STATES ARMY MEDICAL DEPARTMENT

Lecture.

ON TETANY AND TETANILLA.[1]

BY JULIUS ALTHAUS, M.D., M.R.C.P. (LOND.),
Corresponding Member of the New York Academy of Medicine, Senior Physician to the Hospital for Epilepsy and Paralysis, Regent's Park, London.

Amongst the convulsive diseases of the nervous system which we are in the habit of encountering in the practise of our profession, there are some which have, on account of the extreme severity of their symptoms, engrossed the attention of physicians almost from time immemorial. The principal representative of this class is epilepsy, which was for a long time believed to be a special infliction sent by the wrath of the Almighty, being termed morbus sacer by the classical writers. Tetanus arising from injury and exposure to cold, was likewise already well known to Hippocrates and Aretaeus, and has as well as epilepsy and chorea, engaged the attention of innumerable observers, while even at the present day all these diseases offer to those who are willing to investigate them patiently, points of interest that are still involved in obscurity. The complaint to which I intend to refer to-night, has no doubt always existed, like the more formidable diseases which I have just mentioned; but has only been recently recognized as a special entity, partly no doubt on account of its symptoms being habitually much less severe, and partly from having been confounded with other diseases, which although they resemble it in some particulars, are nevertheless totally distinct from the same.

Tetany is not frequent, but where it occurs, presents points of considerable physiological and pathological interest, and as it is occasionally so severe as to lead to a fatal result, it is also practically important for physicians to be familiar with its clinical features and its pathology and treatment.

There is another kindred complaint to which I have for many years past drawn attention at the hospital, and which I have termed tetanilla. I have, however, up to the present time never published my observations on this subject, and was in 1881, forestalled in this point by the late Professor Friedreich, of Heidelberg, to whom we owe such excellent work on muscular atrophy and hypertrophy, and who was also as you know the first to describe that peculiar and unusual form of locomotor ataxy which runs in families and habitually begins about the age of puberty, and which is now generally designated by the name of Friedreich's disease. This able pathologist, whose premature death from aneurism of the aorta we deplored not many months ago, gave to the complaint which I have just introduced to your notice as tetanilla, the somewhat barbarous name of paramyoclonus multiplex. Löwenfeld and Seeligmüller have more recently described cases of this affection; and I will make use of the opportunity which this meeting affords me, to speak of my own experience with regard to it. Of course, I do not in the slightest degree wish to interfere with Friedreich's unquestionable right of christening a disease of which he was the first to record his observations; but I confess that the name tetanilla which I had as it were privately given to the affection, sounds to me much more euphonious than paramyoclonus multiplex; while the fact that both appear to be functional disorders of the nervous system — showing their chief symptoms in closely allied muscular disorder — would seem to favor the idea of giving them somewhat analogous names, expressing at the same time in the word, tetanilla, the lesser degree of severity which the latter form is apt to assume in practice. It will, however, be for the profession to decide which name shall eventually be adopted.

I think I shall do best if I commence my remarks on tetany, of which I have seen altogether ten cases, four in males and six in females, with a short historical retrospect of the work which has been contributed by various authors who have had opportunities of investigating this complaint. I do so more particularly because recent French writers have claimed it as a peculiarly French disease, as one which has, according to them, "une paternité toute française"; the fact being that the first description was given by a German physician, Steinheim, in 1830, while the first French publication by Dance, appeared quite a twelvemonth later: namely, in the *Archives Générales de Médecine* for the year 1831. Of course, it is not to be supposed that Dance should have been acquainted with Steinheim's essay at the time he wrote; for the French have only commenced at a very much later period to read German publications; and when Dance wrote they were in the habit of looking upon everything German or English as only fit for barbarians, whose prescriptions might be good enough for horses, "*médecine de cheval*" being even now a not uncommon term with the French for any foreign system of treatment. At any rate this fact remains that Steinheim was a year in advance of any other writer on the subject, and it seems therefore hardly fair that Delcroix should in his recent thesis on the subject, moved no doubt by the noblest patriotic sentiments, have substituted the year 1830 for 1831, as the date of publication of Dance's paper. I have myself verified the reference, and while I am free to admit that Dance's publication is an unusually able one, have to state that in point of time it is unquestionably the second, not the first. Dance, who was then physician to the Hotel Dieu, at Paris, has given a detailed description of four cases of the affection, and pointed out with considerable minuteness its difference from simple cramps, muscular rheumatism, tetanus, hysteria, as well as certain affections of the spinal cord, nerves and muscles. He laid stress on the paroxysmal character of the spasm, and the favorable issue of all cases in spite of occasionally alarming appearances; and believed the disease to be a kind of intermittent and non-pernicious tetanic fever. I may here say at once that, although Dance's paper is more interesting than Steinheim's, nevertheless the French writer's view of the pathology of the complaint, namely, that it is owing to malaria, has not been confirmed by further experience; while the German author's statements that the rheumatic diathesis is at the bottom of the disease, has, at least for a certain number of cases, turned out to be correct.

The name tetany, which is universally used, originated with Corvisart, in 1851. Trousseau, who in his practice at the Hotel Dieu, in Paris, enjoyed unusual opportunities of studying the complaint, met with it at first only in nursing women, and called it rheumatic contracture of wet-nurses; but he soon perceived that it also arose from other causes than lactation, although he looked upon the latter as the most

[1] Read before the New York Academy of Medicine, October 21st, 1886.

active and frequent causative influence. The complaint was subsequently studied by Moxom, who termed it remittent tetanus, by Wilks, Riegel, and more especially by Kussmaul, (in 1871), whose fine clinical instinct enabled him to draw such a striking picture of the complaint that he succeeded more than any previous writer in attracting general attention to it. Erb, Chvostek, and Weiss are amongst the later authors who have added their quota to the pathology of this disease.

Tetany consists of a succession of attacks of tonic spasm or rigidity of certain groups of muscles, mostly symmetrical, which follow one another at somewhat irregular intervals, and are after a variable time being followed by relaxation. The attacks are not accompanied with loss of consciousness, but there is throughout the course of the complaint undue mechanical and electrical excitability of the motor nerves and muscles.

The chief causes which appear to give rise to tetany, are certain kinds of irritation acting on an otherwise predisposed or enfeebled nervous system. Thus it occurs after and in consequence of persistent diarrhœa, more especially in the underfed and half starved children of the poor. Kussmaul has described the case of a boy aged six, who had been brought up by hand in wretched surroundings, and had lately lived almost exclusively on small beers; indeed, during the first few days the little fellow was in the hospital he refused all food, excepting beer, and suffered from incessant diarrhœa. He eventually recovered from incessant diarrhœa as well as the tetany, but was three months afterwards seized with a violent attack of vomiting and purging, after which the tetany reappeared. The same cause I ascertained in the case of a little girl, aged three, whom I saw at the hospital in 1881, and who had been reduced almost to a skeleton by incessant diarrhœa. The attacks came on in her hands and feet every few hours, and lasted about twenty to thirty minutes, during which time she kept yelling in the most fearful manner. Her mother had suffered from hysterical fits, and a sister had had chorea. Obstinate constipation and entozoa in the intestines have likewise acted as existing causes.

A case is on record in which the ova of tænia medio-canellata and trichocephalus dispar caused tetany, which latter ceased after the parasites had been expelled from the bowels. The irritation of dentition has likewise been assumed to give rise to tetany, although the evidence supporting this point is not strong. Irritation in the sexual sphere of women, and occurring in connection with menstruation, pregnancy, the puerperal state and lactation, is however, an undoubted factor in the production of the complaint. It also occurs after small-pox, cholera, typhoid fever, and other acute diseases; indeed, Aran has seen it occurring in a dozen convalescents from typhoid fever who were in the hospital at the same time. Bauer has also seen it simultaneously in three women of the same family who had eaten unwholesome bread. This had been procured from a distance on account of its cheapness, and was so mouldy and nasty that the men of the family refused to touch it. None of them had tetany, and the three women recovered after discontinuing to eat of this particular bread. Bauer thinks that it may have contained ergot of rye, but could not procure a sample for analysis.

Another active agent in the production of the complaint, and which was chiefly dwelt upon by Steinheim and Trousseau, is the influence of wet and cold. The latter observer describes the case of a man who was found in the streets of Paris one morning in winter, having passed the night there in a state of intoxication, and being so stiff that he was believed to be in an epileptic fit; yet he had been quite conscious all the time. While under observation in the hospital, he was found to be subject to attacks which lasted from a few minutes to half an hour, and had such good use of his limbs in the intervals as to enable him to attend upon the other patients in the wards. On account of the undoubted influence of cold in its production, tetany has also been called intermittent rheumatic contracture. Sleeping habitually in damp rooms, or working in damp shops, appears to favor an outbreak; and exposure no doubt often acts concurrently with other influences. Thus one of the nursing women in whom Trousseau saw tetany, was found to have got out of bed in the night, and gone outside into the yard of the hospital, in order to fetch water from a pump, in midwinter. She died of asphyxia produced by tetany of the respiratory muscles shortly afterwards. In one of the cases which have fallen under my own observation, tetany came on quite suddenly in a young man aged eighteen who had, while skating in the Regent's Park in London, broken through the ice, and had been nearly five minutes in the water before he was rescued. An emotional influence, however, was probably likewise active in this case in addition to the chill; as the patient being unable to swim, underwent an agony of fear of drowning all the time he was in the water. It is not uncommon that there should be several influences at work in determining the outbreak of a nervous affection; I will only remind you of tabes spinalis, in cases of which we generally find a history of three causes, namely, syphilis, exposure to cold and wet, and over-exertion, whether physical or mental.

An emotional influence was likewise evidently at work in another case of tetany which was under my care in 1879, and which was that of a young lady, aged twenty-one, who had been engaged to be married, and in whom the disease appeared quite suddenly the day after she had had a quarrel with her lover, in consequence of which her engagement had been broken off.

Simon and Regnard have described what they call an epidemic of tetany, which occurred at Gentilly in France, where it went through a young ladies' school. At first the cases were very few; one girl was affected in July, and another in October; in November, however, quite an epidemic broke out, there being eight new cases on one day, and eleven on the next. The governess at first tried to arrest the progress of the disease amongst the girls, but eventually got it herself. The school was then broken up and all the girls recovered rapidly. Similar epidemics have been described as having occurred in some prisons and asylums in Belgium. It is, however, quite clear from the description given of the epidemic amongst the French schoolgirls that there was no real tetany present, but that it amounted to an endemic manifestation of hysteria which in its symptoms had a considerable resemblance with tetany. We know that hysteria may mimic most diseases, and need therefore not be surprised that it will occasionally mimic tetany. With regard to the cases observed in the public institutions in Belgium, it appears probable that they were

in reality cases of epidemic spinal meningitis, as in some of them an inspection was obtained showing the pathological lesions of meningitis; and I shall presently in my remarks about the diagnosis of tetany, refer to the possibility of its being occasionally confounded with that disease. It is, however, a fact that cases of tetany do sometimes occur together; but the explanation of this would seem to be the influence of exposure to unusually severe cold prevalent at the time. Thus Weiss had twelve cases under his care in the severe winter of 1881, at Vienna, and Chvostek saw seven in the winter of 1880, in Austrian soldiers, who during target practice suffered considerably from exposure to the unusually intense cold which then prevailed.

In May last, Ord, of London, exhibited at the Medical Society of that city, the case of a woman who showed the usual symptoms of myxœdema, and, in addition to them, a peculiar symmetrical contracture of the flexor muscles of the hands and legs, strongly resembling tetany. In connection with this case, it is interesting to remember that Weiss should have seen four cases in which the excision of the enlarged thyroid body, by Professor Billroth, of Vienna, appeared to give rise to the affection. In one of these cases it appeared on the sixth day after the operation, in a second on the evening of the same day, and in two other instances immediately afterwards. One of these patients eventually died of it. In another case, this tetany lasted six days after the operation, then disappeared, but relapsed when an abscess had formed in the neck; it ceased finally after this had been opened and healed. Weiss does not assume any particular relation to the bronchocele, but thinks that it was only the irritation caused by the surgical operation *per se*, which caused the tetany; yet it seems a curious coincidence that four cases of tetany should have appeared in connection with thyroidectomy, while it is not known to have occurred after any other surgical operation; and in connection with this, Ord's case, which I have just mentioned, is of interest, as raising the question whether there may not be some more intimate connection between atrophy or absence of the thyroid gland and tetany than has hitherto been assumed. I would recommend this point to your attention, should similar cases present themselves to you in your practice.

Tetany has probably no connection at all with certain kinds of occupation, as has been assumed by some writers. Indeed, it has by some been termed cramp of tailors, cobblers, and seamstresses, or professional spasm generally; but the fact that it not uncommonly affects infants, as well as women who have no particular kind of manual labor to perform, and finally, in men addicted to all kinds of occupations, speaks strongly against this assumption. The age at which it is most frequent is the period between one and five years, and again, that between fifteen and thirty years. As to the influence of sex, females seem to be rather more liable to it than males.

On reviewing all the different determining influences which I have just mentioned, it is impossible not to be drawn to the conclusion that they can, one and all, only be looked upon as exciting causes, and that a constitutional neurotic disposition must be present in patients, in order that such causes as cold, diarrhœa, etc., may be effective in leading to the outbreak of tetany. As, however, this point has not as yet been very clearly made out, I have taken some trouble in gaining information upon it in those cases which have happened to come under my care. The result has been that in not a single case was there any direct heredity, for to all my patients and their friends and relations the disease was entirely new, and something they had never known or heard of. In five out of ten cases I have seen, however, such diseases as hysteria, migraine, epilepsy, and chorea had occurred in the parent, or other members of the same family. This would already give a proportion of fifty per cent., but I have to add to this a case of atavism, as the maternal grandfather of one of the patients had died insane; and another case, where the parents of the patient were first cousins, and where, therefore, a neurotic predisposition might be assumed to exist. It is, therefore, seen that only three cases out of ten were, or appeared to be entirely free from a neurotic taint, so that my contention of a constitutional tendency being at the base of the complaint, would appear to be well substantiated, more especially when we remember that either through ignorance or carelessness of the persons concerned, the family history given us in such cases is frequently far from complete.

The evolution of the symptoms of tetany may be somewhat rapid, or more gradual. In some cases, and according to my experience, more especially in those where a cause has acted very suddenly, the disease may appear at once fully developed, while in those where the power of resistance of the nervous system appears to have been more gradually undermined by various deteriorating influences, there is a progression in the symptoms, which goes from piano through the different degrees of crescendo up to forte, and eventually to fortissimo. Amongst the premonitory symptoms, where such are present, we find more particularly a general feeling of malaise, as of some impending illness, headache, dizziness, specks floating before the eyes, and a feeling of stiffness and awkwardness, or shooting pains in the limbs. Slight temporary rigidity of certain muscles may be combined with this, or there may be a few twitches, which subside again presently. These symptoms generally become aggravated, and eventually, tetany sets in. Both hands are then seen to have assumed a peculiar position, which is not always the same, but varies according to the several groups of muscles which may happen to be affected. In most instances, it is the muscles supplied by the ulnar nerve which suffer; in some, those under the control of the median nerve, while only very occasionally those which receive their motor impulses through the musculo-spiral nerve are affected.

In accordance with this, it is found that the common position of the hand in tetany is the conical one, resembling that which the accoucheur uses when introducing his hand into the vagina. In this the thumb is forcibly adducted, and the other fingers are flexed in the metacarpo-phalangeal joint, and pressed against the thumb, while the wrist is bent, and turned towards the ulnar side of the arm. The spasm may stop there, or proceed higher up, involving the forearms, which may be bent, and crossed over the epigastrium, and the arms, which may be strongly adducted to the body.

In some cases, again, the fingers are so strongly clenched that the nails enter the flesh, and produce eschars; the thumb may almost disappear underneath the other fingers, or it is squeezed between the first and second finger, so as to show the thumb-nail between their first phalanges. Where the interosseous

and lumbrical muscles are rigid, the hand assumes the bird-claw position which was first described by Duchenne; or there may be spasm in the extensor muscles, the fingers and wrist being stretched out, and unable to be bent, and the fingers being wide apart from each other. A considerable variety of positions may thus be produced, and it is, therefore, important to remember that the position of the hand which was first mentioned is not absolutely pathognomonic of the disease. At the same time, there is in true cases of tetany always some degree of rigidity in the muscles supplied by the ulnar nerve, and when this is entirely wanting, the case is most probably not one of tetany.

In the lower limbs the spasm is generally seen to begin in the toes, which are held in plantar flexion, closely pressed against each other, but extended in the metatarso-phalangeal joint. The big toe is adducted and beneath the others the foot in the varo-equine position, with the heel drawn up, and the tendon Achilles strongly retracted; or again the toes may be stretched out, and each one be as wide apart from its neighbors as possible. The feet may be adducted, the knees extended, and the thighs stretched on the pelvis, while in other cases the legs are drawn up to the abdomen. Walking during the attack is thus rendered difficult or impossible; indeed, sometimes there is persistent contraction of the muscles of the calves, so that the patient is quite prevented from moving about, while in other cases the rigidity is so distributed that only the heel touches the ground, and the toes are raised up. The effect of this is the same, namely, to interfere altogether with walking.

In some cases only one side of the body, or only the upper limbs, or only the lower ones are affected, or they may suffer alternately, but mostly there is symmetrical affection in both sides of the body.

In the large majority of cases, only the muscles of the extremities are thus affected; but in some the rigidity also involves those of the head and body. The head may be pulled down on the chest, and the spine curved; the muscles of the neck may be so rigid as to stand out like tight cords, and to compress the jugular veins; the lips and tongue may be quite rigid; the eyes may be spasmodically closed, and through contraction of one or the other of the ocular muscles, the various forms of strabismus may be produced. The face may appear statuesque, and devoid of any mobility of features. The muscles of the lower jaw, and of the pharynx and larynx, likewise do not escape in some cases, and this leads to difficulty in masticating, swallowing and breathing. In extreme instances there is spasm of the glottis, with great dyspnœa and cyanosis. The diaphragm and the other muscles of inspiration then appear to be fixed, and if this condition is not speedily relieved death from apnœa is the result. Even the bladder may suffer, as shown by retention of the urine, together with frequent desire to micturate. A very bad attack, in which dyspnœa may be so severe as to threaten the life of the patient, sometimes ends with profuse perspiration, and as soon as this is well established, all symptoms are relieved. In one of Dance's cases, perspiration was so abundant as to form a regular cloud of steam around the patient.

The contraction of the muscles is sometimes very painful, and more especially so in children, who often scream and yell throughout the attack. In other cases there is rather a stiff and bruised feeling than actual pain, together with great tenderness on pressure. The degree of contraction may vary from one minute to another, and this occasionally leads to spasmodic jerkings of the muscles. Where there is much pain, the patient is restless and agitated during the night, and desires constant change of position, while another may lie still in bed like a statue. During the attack the muscles may be entirely withdrawn from the influence of volition; in other cases the rigidity is more moderate, and allows of some degree of movement. Habitually the muscles feel as hard as iron. In a severe case there is so much resistance to passive movements that a great deal of force is required to counteract the rigidity, and the instant we let go the contraction re-asserts itself. Attempts to overcome the rigidity are very painful. Friction often diminishes the rigidity, while pressure may increase it. A sudden impression of cold and heat may also arrest the spasm; thus, if the patient be made to stand with his naked feet on the bare floor, or if his hands be immersed into vessels filled with hot or cold water, the rigidity may relax, but only to re-appear again as soon as the influence of these agents is withdrawn. The duration of the attack is variable; it may last only five minutes, or as many hours, and may be repeated over and over again, but when the condition appears to have continued for days together, it is probable that, as in certain cases of epileptic fits, the intervals have been short, and remained unnoticed by the attendants. If this should not be the case, then I would say that the case was not one of tetany.

Trousseau was the first to notice that, as long as the diseased condition persists, we may, at a time when the patient is quite free from rigidity, produce it almost immediately by compressing the affected limbs, more especially at points where we can act on large nerves or vessels, so as to interfere with circulation. This discovery was made accidentally. He had ordered a woman suffering from tetany to be bled, and noticed that when the bandage was drawn round the arm, the muscles below tightened. He afterwards found that such an effect is produced, more especially with the upper limbs, where pressure on the brachial plexus above the collar-bone or the median nerve in the arm, will lead to it. In the lower limbs, pressure on the sciatic nerve or the femoral artery may do the same, but here the result is not so quick and certain as in the upper limbs. In one case, Trousseau found a very suggestive illustration of the well-known law of reflexes formulated by Pflüger, namely, that the effect of the stimulation is greatest at or near the spot where it is applied, and that an increase of stimulus is required for affecting more distant parts, which are then acted upon in a certain order. In that case, ligature of the right thigh produced first contraction in the toes of the right foot, then in those of the left foot, afterwards in both hands, and finally, a violent attack of hysteria.

Kussmaul was led by his observations on this symptom to the result that it is pressure on the arteries, rather than on the nerves, which causes these effects in the muscles. When he compressed the brachial artery of a patient during a free interval, he noticed that in twenty or thirty seconds the fingers began to twitch; in two or three minutes the flexion appeared to be increasing, and very soon afterwards the hand and forearm were spasmodically bent. The proceeding was not painful. When the pressure was with-

drawn, the spasm disappeared, and pressure on the nerves did not cause the same effect.

My own observations have led me to the result that Trousseau's symptom is produced by pressure both on the nerves and on the bloodvessels, and that complete compression of the latter leads more quickly to the expected result than that of the former. This is more particularly seen in the lower extremities, where compression of the femoral artery in front of the os pubis brings about muscular twitches and rigidity much more rapidly than compression of the sciatic nerve in its notch.

My study of this point has also led me to a very singular observation, which is likely to prove of some importance in the diagnosis of tetany from hysterical contracture, as it tends to show that tetany and hysteria are two widely different conditions. I have seen cases of hysterical contracture closely resembling the habitual position of the hand in tetany, where the history of the case was obscure, and it was difficult to make out whether the muscular rigidity was paroxysmal, as it is in tetany, or continuous, as it is in hysteria. In these cases compression of the limbs by Esmarch's bandage enabled me to decide this question; for it appeared that while in tetany pressure increases the rigidity still further, on the contrary, in hysterical contracture the rigidity was relieved, and ceased after the bandage had been applied for some time, to return however again almost immediately after the pressure was withdrawn. This singular circumstance seems to show that the arterial anæmia and venous congestion which is produced in a limb by compression, may cause opposite effects according to the condition of the nervous system with which we may have to deal, leading in one case to contraction, and in another to relaxation of the muscles. This is a point which much requires further elucidation, and the study of which I would recommend to you in similar cases, as it may eventually throw light on the more intimate nature of the vaso-motor disturbance which is present in such conditions as hysteria and tetany, and of which we are as yet in almost complete ignorance.

PANCREATIC HÆMORRHAGE AND SUDDEN DEATH.[1]

BY F. W. DRAPER, M.D., BOSTON,
Assistant Professor of Legal Medicine, Harvard University, Medical Examiner, Suffolk County, Mass.

SAFE in its secluded anatomical position, the pancreas rarely challenges attention as an organ of clinical or pathological interest. When compared with its neighbors among the abdominal viscera, it is content to hold a modest secondary rank. Ordinarily, it eludes the touch of the clinical observer's fingers, and it is too often neglected by the pathologist's eye and scalpel. The liver, the kidneys, the stomach, the intestines and, preëminently, the uterus, have abundant reasons for regarding their unobtrusive racemose associate as of slight relative consequence, if volumes, and pamphlets, and other medical writings can count as proof.

But although the pancreas does not pretend to merit distinguished attentions, or push itself into notice like the womb or the liver, although it does not enter into the title of thick volumes devoted to its study, it occasionally becomes the subject of clinical curiosity. Its privacy is invaded by neoplastic intruders or by the assaults of inflammation, and it is then that its right to be is demonstrated by the digestive disturbances which its impaired functions entail. Parenchymatous and interstitial fatty changes, purulent and fibrous processes of inflammatory origin, both acute and chronic, alterations due to syphilis and the presence of tumors, gummatous, tuberculous or carcinomatous (especially the last), amyloid degeneration and affections of the excretory ducts, retention-cysts either inflammatory or calculous,— these comprise the short list of diseases of the pancreas which modern pathology recognizes. How obscure and rare these affections are, the brief space devoted to them in the standard works of our best writers gives ample proof; their diagnosis, except at the autopsy, and their treatment are among the *opprobria medicinæ*, as all clinical masters admit.

But it is not with these truly recondite diseases that this note is concerned. The purpose of this brief paper is to illustrate a rare accident to which the pancreas is liable, and to place on record some observations relating to an unusual cause of sudden death in which this hidden organ plays an important part.

It is but recently that attention has been called to the fact that hæmorrhage within and around the pancreas quickly eventuates, in many cases, in the death of the patient, the fatal issue resulting either immediately after an interval to be measured by minutes, or, secondarily, after a few days. It is for the purpose of adding some new examples of the former of these two classes, the relation of pancreatic hæmorrhage to *sudden* death, that these notes are offered. They are intended as additions to the brief list already on record, and as a response to the suggestion of Friedreich who, commenting on Zenker's observations, writes: "Cases such as those related by Zenker merit great attention, and it must be an object with future workers to increase the statistical material by the addition of fresh cases."[2]

A single word is proper here relative to the instances of sudden death which are described. They are cases of persons found dead under circumstances requiring a medico-legal investigation. Under the system of inquests at present and for the past nine years in successful operation in Massachusetts, sudden and violent deaths become the subject of inquiry in a manner greatly in contrast with the antiquated and objectionable method of inquest by the coroner and his jury. Instead of the inverted and dilatory plan which first summons a coroner in a case of violent or sudden death and leaves to his often clumsy judgment the question of an autopsy, and who shall make it, for determining the cause of the death, the Massachusetts law places the case at once in the hands of a medical man commissioned by the State, and directs him to ascertain the cause and manner of the death, by autopsy if he deems it necessary, and to report the results of his examination to the proper judicial officers, if he is of opinion that the death resulted from the act or neglect of some person other than the deceased. An inquest then follows, the evidence being taken

[1] Read by title at the meeting of the American Association of Physicians and Pathologists, June, 1886.

[2] Ziemssen's Cyclopædia of Medicine, vol. viii, p. 624.

and properly sifted by a judge fully competent for such a duty, and the entire investigation becomes, in this way, in fact and in name, a truly medico-legal one, its different stages following in natural consecutive order. It thus happens that many sudden and mysterious deaths which are accounted for usually under the familiar and convenient formula "heart-disease" receive a truer and more scientific interpretation under a system which favors or requires well-ordered post-mortem examinations; and it was in this way that the writer, holding a commission as a medical examiner, came upon what may seem an unusual number of rare cases, which he now places on record.

CASE I. Humphrey L., aged forty-five, a strong and rugged laboring man, lived alone in two rooms upon the ground floor of a tenement-house. He was found dead in his front room late in the afternoon of Monday, October 20th, 1884. He had not been seen during that day or the previous day (Sunday), but he was at work all day Saturday, and in the evening of that day appeared in his usual robust condition of health. He was not intemperate in the use of alcohol, and indulged to inebriety at long intervals only.

When discovered, his dead body, fully clothed, was in a sitting attitude in a chair, the hands resting naturally on the knees and the head dropped forward upon the breast. He had the posture and appearance of one asleep in his chair. The condition of the room gave no indication of illness or distress on the part of its occupant before his death; there was no vomitus or sign of an attempt to prepare or to take domestic or other remedies. When and in what manner death claimed its victim, could only be guessed; the body was cold and cadaveric rigidity was developed to an extreme degree. The only suggestion which the surroundings offered upon the matter of the time of the death was the fact that the bed-clothing was turned down away from the pillow, the natural act of one about to get into bed. The autopsy was made twenty hours after the discovery of the body. Rigidity continued in its fullest degree. There was moderate cadaveric lividity of the skin of the lower part of the back, the thighs and the legs. The lips and the ears were of a violet color. The tongue was in normal position. The corneæ were bright; the pupils measured three millimetres in diameter. The body presented no marks of violence, but was that of an exceptionally strong and muscular man, with little adipose. The heart was normal in every particular. The blood was dark in color and almost wholly fluid, only a few soft, dark clots appearing. The right auricle and ventricle were moderately filled, but not distended; the left ventricle was contracted and empty. The lungs were somewhat emphysematous. Quite general, firm pleuritic adhesions had obliterated the right pleural cavity. There was moderate gravitation injection of the lower parts of both lungs, with some œdema of the right lower lobe. The spleen, kidneys and liver showed nothing noteworthy beyond a very moderate degree of injection. The stomach contained a little less than a pint of thin, gruel-like material, having the gross appearances of oat-meal and milk recently ingested. The gastric mucous membrane was of a dull brown color at the fundus of the organ, especially marked at the summits of the rugæ; elsewhere it was normal. There was no odor of alcoholic liquor.

When the stomach and intestines were turned aside, before any of the abdominal organs were opened or disturbed, the region of the pancreas showed, beneath the peritoneum, the dull red color of extravasated blood in the sub-peritoneal tissues, extending over a space a hand's breadth in diameter. Upon section of this area and exposure of the pancreas, it was found that the organ lay in a mass of effused blood, and was itself infiltrated with blood throughout its extent, but more especially in its outer half, toward the tail, while the outer third was not only deeply stained with blood, but was softened to a marked degree.

The splenic artery was very tortuous, and somewhat enlarged. The intestines were normal in appearance, and contained normal fæcal matter. The brain gave no appearance of disease, or of abnormal blood-supply.

CASE II. Mary E. H., aged forty-four, was found dead in her bed, at noon, November 3d. She lived in wretched squalor in an attic, getting a scanty income as a charwoman. She drank beer every day, her neighbors said, but was rarely intoxicated. She was seen at 6, P. M., the day before her death, and was apparently in perfect health. She went to bed with her boy, a lad of about ten years: the latter stated that nothing occurred in the night out of the usual course. The woman got up in the morning and dressed herself; presently, she complained a little of her head, and soon went to bed without undressing. The boy went to school, and on his return home found that his mother had died in his absence, and was lying where he had left her. Just when, or under what circumstances the woman died, no one knows. She made no complaint to her neighbors, and her statement to her boy that her head felt badly was the only suggestion that she was in any way ill. I saw her dead body at 2.20, P. M., and rigor mortis was then fully established, and the face showed marked lividity.

The autopsy was made twenty-four hours later. Post-mortem rigidity was as pronounced as at the first inspection, and the face, lips, tongue, and neck were livid. The tongue protruded as far as, but not outside the lips. The pupils were small; the body was emaciated.

The heart was normal in structure. It contained dark, clotted blood, the amount in the right cavities being relatively large. The lungs were much reddened in the dependent parts, but were of natural appearance in front and superiorly. They were crepitant everywhere.

In the depressions of the peritoneal cavity, about eight fluid ounces of thin, red fluid were found; there was no other sign of hæmorrhage within the peritoneum. The spleen was soft and deeply reddened. The kidneys were normal; the liver was healthy. The stomach was reddened somewhat at its cardiac end, but in other respects was normal in appearance. The intestines presented nothing abnormal; the mucosa was pale. The colon and rectum contained normal fæces.

The pancreas was infiltrated with blood throughout its extent, most markedly at its splenic end. There was a moderate amount of blood effused in the retro-peritoneal tissue. The organ itself showed nothing remarkable on section, beyond the hæmorrhagic infiltration above noted. Its size was not increased.

The womb was healthy: the ovaries were atrophied. The vessels of the scalp, skull, and dura were injected. There was very moderate injection of the pia. The

brain showed no change, in its gross appearance, from the healthy condition.

Case III. Catherine F., aged twenty-six, had many quarrels with her husband on account of her intemperate habits. A week before her death she came home one night fully intoxicated. Her neighbors heard the usual family dispute, but did not interfere to check it. Her husband stated that he put her to bed, but denied the use of any violence. Next day he left her, and did not see her again to speak to her until he was summoned to her, just before she died. During the week following the separation, Catherine stayed with friends, who lived at some distance from her home; she complained to them of the abuse which, she stated, she had received from her husband, and especially, accused him of kicking her in the abdomen, in proof of which accusation she showed an ecchymosis near the umbilicus. She seemed none the worse for the alleged assault, however, and went out repeatedly during the week in apparently her usual health. She was not intoxicated at any time in this interval. She was seen walking on the street the night before the symptoms developed which preceded her death. Twenty-four hours before she died she went to bed, complaining of great pain in her abdomen. There was no vomiting; she "spit up some blood." Her abdominal pain was relieved by brisk rubbing over its seat. Fourteen hours after the onset of the illness, a physician was called, who found the woman pulseless, with a pale, cold skin, covered with clammy perspiration. Her mind was clear. She complained of the abdominal pain, and of intense thirst. A hypodermic injection of morphia afforded partial and transitory relief, but the complaints of pain in the abdomen continued until death, the day after the seizure. Her reiterated charges of her husband's violence led to his arrest, and to a medico-legal investigation of the case.

The autopsy was made twenty-four hours after death. The body, which was very fat, had been in an ice-box; there was no sign of decomposition. There was a slight degree of rigor mortis, and moderate lividity of the depending parts. The lids of both eyes showed the changing colors of a retrograding ecchymosis. There was a faint bruise-discoloration on the outer side of the left shoulder, and another, an inch and three-quarters in diameter, three inches to the left of the umbilicus; the color of the latter ecchymosis was a dull brownish-red, and it was evidently several days old. The heart was normal, and the blood was not noteworthy. Both lungs were over-filled with blood, but were crepitant in every part. The bronchial mucous membrane was deeply reddened, and the trachea and bronchi contained frothy blood.

In the abdominal cavity were twenty-two fluid-ounces of thin, red fluid. Beneath the peritoneum of the mesentery, in the entire region behind and below the stomach, between the stomach and the colon, and the liver and the colon; also, along the right flank behind the ascending colon, and over the right kidney, the sub-peritoneal tissues were fully infiltrated with blood.

The pancreas were completely filled with effused blood throughout its extent, but the change was especially marked in its middle part and at its tail. The organ presented a sodden, soft, and slimy appearance, its structure being greatly obscured in the dark, bloody extravasation. Its volume was increased, and its middle part was so soft as apparently to be ready to break down upon the slightest roughness in handling. There was no sign of peritonitis. The bruise on the surface of the abdomen was found to be superficial. The spleen was normal. The kidneys were pale, of normal size, with free capsules. The liver presented the gross appearances of fatty changes; its weight was five pounds and ten ounces; its edges were round; on section, the edges of the incision were markedly everted, and a smear of fat was left on the knife-blade. The stomach, intestines, pelvic viscera, and brain and its membranes were normal.

Case IV. James T. S., aged fifty-five years, a pressman in a wholesale clothing house, was found dead on the floor of his bed-room. He was a man of exemplary habits and unstained reputation, taking an active interest in social and religious affairs. He went to his work as usual in the morning of the day of his death. At about ten o'clock on that morning, he complained of "cramps," which were so severe as to oblige him to desist from his work, and to lie down; presently, he left the store, saying that he would go home. No one saw him entering his house, or going to his room, but between six and half-past six that evening, a friend called to see him, and found him lying dead on the floor of his chamber. The carpet was wet all about him, and an empty tin dipper lay by his knees. The oil-stove was alight on his table, and a tea-cup containing extract of ginger, with water and sugar, was beside it. The body lay on its left side; it was cold when found, and rigor mortis was fully developed.

The autopsy was made at ten o'clock in the morning following the death. Cadaveric rigidity was fully developed, and there was marked lividity of the back and shoulders and sides of the neck. The outer side of the left leg was vesicated from the knee to the ankle, the cuticle being off in large patches.

The heart was normal. The blood was equally distributed in its cavities.

Both lungs were injected posteriorly and inferiorly, the left rather more than the right (post-mortem position). When the stomach and liver were lifted, the tissues outside the peritoneum, at each side of the pancreas, were seen to be fully filled with blood. The pancreas itself was larger than normal, and the entire organ was uniformly infiltrated, from its head to its tail, with recently effused blood; the hæmorrhage was most marked in the central parts. The extravasations extended about two inches on either side of the pancreas into the surrounding tissue. There was a small amount, not exceeding half an ounce, of red fluid in the peritoneal cavity. The spleen was healthy. The left kidney was injected, but showed no other change. Its fellow was healthy in appearance. The gastric mucous membrane presented a few limited patches of redness near the fundus. The stomach contained about four fluid-ounces of thin fluid, giving a strongly marked odor of ginger. The liver was moderately injected, but its structure was normal. None of the other organs or regions of the body gave indications of disease or injury.

To the foregoing cases, another which has come under the writer's observation is added, although it has appeared in another connection.[2] It is reproduced here, because its clinical features are especially interesting, and because a careful microscopical examination of the pancreas failed to reveal the fatty changes

[2] Medical and Surgical Reports of Boston City Hospital. Third Series. 1882. p. 128

which some authors have declared to be a characteristic of this lesion.

CASE V. The patient in this case, a printer, thirty-one years old, of intemperate habits, was seized suddenly with pain which he referred to the epigastrium. Up to the time of this attack he had been in good health. At noon on the day of his death, he ate his usual hearty dinner. The pain of the attack, which began about six o'clock, P.M., was soon followed by nausea and an ineffectual attempt to vomit. Presently collapse supervened; the patient was scarcely able to speak; he fell from his chair to the floor; he was evidently in extreme distress. While in this condition he was seen by a physician who prescribed a stimulant (hot brandy) which seemed to produce a temporary reaction and relief. The patient died a few minutes later while in a carriage on his way to the hospital, in less than forty-five minutes after the seizure.

The autopsy was made nineteen hours post-mortem. The body was that of a man in apparently vigorous health at the time of his death, and showed no excess of adipose tissue. The heart was moderately enlarged and the left ventricle was dilated. The muscular tissue of the organ was of good color but was quite friable. The intima of the aorta showed the products of a former endarteritis. The blood was liquid and of dark color. Both lungs were injected and the upper portions were moderately œdematous. The bronchial mucous membrane was thickened and reddened and was covered with muco-purulent secretion. The kidneys and spleen were injected. The pancreas was normal in size, shape and position. The organ itself and the retro-peritoneal connective tissue adjacent to it were infiltrated with blood — not to a degree to form a free clot at any point, but involving nearly two-thirds of the body of the organ and spreading above and below to the distance of about an inch in each direction. The hæmorrhage was most abundant at about the centre of the pancreas; section of its substance found the interior deeply stained of a dark red color by the blood effused in the interlobular tissue. The splenic artery was enlarged and tortuous; its intima was rough and had a velvety or finely granular appearance. The muscular tissue outside the peritoneum and connective tissue was of healthy appearance and wholly free from blood-staining. The intestines and stomach were normal; the latter organ contained a quantity of half-digested food. A microscopical examination of the pancreas, made by Dr. W. F. Whitney, found the interlobular tissue infiltrated with blood which had permeated among the cells in many places; here the corpuscles were destroyed. The cells themselves were very granular, but osmic acid failed to show the presence of fat in them.

As already intimated, these notes have as their purpose the illustration of an unusual and hitherto rarely recognized form of sudden death. They do not pretend to demonstrate or sustain any particular theory of the actual cause of death in these cases, but rather they are offered as evidence of the fact that sudden death may and does occur with pancreatic hæmorrhage as the single important anatomical lesion revealed in the course of the pathologist's inspection. The true pathology of these hœmorrhages, why they occur, and how, when occurring, they kill their subject so quickly, — these are still unsettled questions; it is permitted to indulge in speculation touching this important part of the subject, but much more investigation and close anatomical study are needed before demonstration takes the place of guessing. It is clear that the fatal issue does not rest on the hæmorrhage alone, the amount of blood lost being generally insignificant; but whether, as Zenker suggests, the mortal blow comes through the sympathetic nerve, the semi-lunar ganglion receiving a sudden and violent shock in consequence of the outflow of blood in its immediate neighborhood; or the death is by general shock because of the rapid hæmorrhagic distention of an organ whose tissues are not readily distensible; or the hæmorrhage is simply an incidental accompaniment, or symptom, of some hitherto unrecognized lesion of the central nervous system; or nutrition is impaired in the pancreas, and its vessels are weakened, by the growth of fat-tissue and its pressure on the blood-vessels, causing at length a necrosis of the interlobular portions of the glands,— the writer does not undertake to be dogmatic in deciding. Each view has great obstacles in the way of its acceptance, because all cases observed do not harmonize with it. The histological condition of the pancreas incidental to such cases needs farther elucidation especially.

More cases, too, are needed for the study of the subject on its clinical side. At present, our knowledge of the symptoms is quite limited. They are comprehensively summarized by Prince as follows:[4] "The patient, who has previously been perfectly well, is suddenly taken with the illness which terminates his life. . . . When the hæmorrhage occurs, the patient may be quietly resting or pursuing his usual occupation. The pain which ushers in the attack is usually very severe and located in the upper part of the abdomen. It steadily increases in severity, is sharp or perhaps colicky in character. It is almost from the first accompanied by nausea and vomiting; the latter becomes frequent and obstinate, but gives no relief to the pain. The patient soon becomes anxious, restless and depressed; he tosses about and only with difficulty can be restrained in bed. The surface is cold, and the forehead is covered with a cold sweat. The pulse is weak, rapid, and sooner or later imperceptible. The abdomen becomes tender, the tenderness being located in the upper part of the abdomen or epigastrium. Tympanites is sometimes marked. The temperature in most cases is either normal or below normal. The bowels are apt to be constipated. These symptoms continue without relief; those which are most striking being the pain, vomiting, anxiousness, restlessness and the state of collapse into which the patient soon falls."

In this brief memorandum of an interesting and rare form of sudden death, no mention has been made or reference intended concerning any class of cases other than such as may properly come within the designation of pancreatic apoplexy. Other instances in which the patient survives the first shock of injury to the pancreas and dies as the result of secondary processes (gangrene, peritonitis), or in which there are well-marked organic changes, either in the pancreas or organs adjacent to it, to explain the hæmorrhage, are intentionally omitted from present consideration.

The English Journals are calling attention to the immorality associated with the practice of massage in many of the establishments for that purpose.

A CASE OF PNEUMOTHORAX.[1]

BY J. F. A. ADAMS, M.D., PITTSFIELD, MASS.

The interesting features of this case are that it was a simple pneumothorax, of peculiar origin, persisting for five years and terminating in spontaneous recovery.

A man, aged forty-six, of American birth and parentage, widower, carriage-painter by trade, was admitted to the Pittsfield House of Mercy as a patient, February 3d, 1881. The previous history of the case, as learned from his own statements, is as follows: Two years previously, having, up to that time enjoyed perfect health, he took a severe cold and was attacked with what was called by his physician "pleuro-pneumonia" of the left side. After being ill, as he thinks, about three days, while straining at stool, he was suddenly attacked with dyspnœa, which had continued without relief up to the time of admission. Two or three days after the dyspnœa commenced, he began to cough and had coughed ever since, usually without expectoration. He had lost appetite, flesh and strength, but had not been confined to bed. A few weeks before admission he was examined by Dr. F. K. Paddock, who found tympanitic resonance and absence of respiratory sounds on the left side. He then consulted Dr. Austin Flint, Sr., who, in a letter to Dr. Paddock, gave a guarded diagnosis, but suggested that the obstructed respiration might be due to pressure upon the left primary bronchus by an aneurism of the aorta; though no physical signs of aneurism were discoverable, and this diagnosis was made only by exclusion.

On admission, he came under the care of Dr. Vermilye, who found him feeble and haggard, with a small and compressible pulse of 86. No pain in the chest, but considerable dyspnœa, especially on exertion. Left chest tympanitic on percussion, with an entire absence of respiratory murmur. He was treated with potassium iodide in five-grain doses, with quinine and iron.

A month later, a faint vesicular murmur could be heard over a limited area of the upper portion and front of left chest, and pain was felt in the same region. Otherwise his condition was unchanged. The iodine was continued till June 1st, a period of four months, after which he took grindelia robusta for two months, neither remedy producing any apparent change in his condition.

On October 6th, eight months after admission, he was examined by myself, and the following record made:—

Left semi-circumference of chest 17 1-2 inches.

Right semi-circumference of chest 16 1-2 inches.

Extreme expansion 3-4 inch.

Expansion of left side 1-4 inch.

Expansion of right side 1-2 inch.

Intercostal spaces fuller on left side than right, and palpation shows left side nearly immobile during respiration. Left side of chest everywhere tympanitic, about equally so over all portions. The tympanitic resonance in front extends to the right margin of the sternum. Cardiac dulness entirely to right of sternum, extending from its right margin to a line one inch to right of the right nipple, and from the third to the sixth rib. Apex-beat close to the right edge of sternum at level of sixth rib. Vesicular murmur heard very faintly over a very small area on left side, at the level of axilla, both in front and behind. Elsewhere, on the left side no sound whatever can be detected. On the right side, respiration is normal. No aneurism or murmur can be detected. Patient still suffers with dyspnœa, which is constant, even when at rest, and excessive on exertion. He complains of a feeling of weight or oppression in the chest, especially at the upper part, amounting sometimes to pain. Pulse 80, soft and weak. Is still feeble and has not materially changed since admission. Has an occasional dry cough.

This patient became a permanent resident at the House of Mercy, remaining there for nearly four years. For three years there was but little change in his condition. He was examined from time to time by myself, as well as by several others of the attending physicians, and the physical signs were found unchanged. He was debilitated, but not confined to bed, went out in good weather and spent his time in reading and acquiring the art of stenography. For treatment he had only tonics and general good care. He left the Hospital for six weeks in February and March, 1883, thinking himself able to go to work, but returned with a severe attack of bronchitis on the right side. This soon passed off, and no change took place until about March 1st, 1884.

At this time he noticed that he could feel the heart beating at a point a little to the left of the position it had so long occupied; and thereafter he was conscious of a gradual progress of the apex-beat toward the left, until, by the latter part of May, he could feel it in its normal position, the change having taken place in something less than three months. As the heart moved, the dyspnœa gradually diminished, and he soon began to regain flesh and strength. I was away at the time the change occurred, and did not examine him until the 25th of the following September, when his condition was as follows:—

Resonance on percussion normal and equal over both sides of chest. Vesicular murmur is now heard in its normal situation, over both sides, the only difference being that it is not quite so loud and strong on the left, where it has also a slight tremulousness or cog wheel character. Apex-beat of heart is found one and one-half inches below and one inch to the left of the left nipple, being six inches in a direct line from its former position. Area of cardiac dulness somewhat greater than normal. He is now able to walk at a brisk pace without dyspnœa.

He remained at the House of Mercy till January 1, 1885, when he was discharged well. Since then he has enjoyed good health, and has been able to earn his living as a stenographer. His normal weight before this illness was one hundred and forty-five to one hundred and sixty pounds. While at the House of Mercy he weighed one hundred and twenty-five pounds, increasing to one hundred and forty before his discharge. His present weight is one hundred and eighty. He writes me that he has no cough, dyspnœa, nor pain in the chest. He still feels the apex-beat to the left of the nipple.

The diagnosis of pneumothorax in this case was based upon the following symptoms:

First. Uniform tympanitic resonance over the left chest.

Second. Distension of the affected side.

Third. Absence of all respiratory sounds.

[1] Read before the Berkshire District Medical Society, September 29th, 1886.

Fourth. Displacement of the heart.

The only question could be between this and a unilateral, pulmonary emphysema, but in emphysema we never get the absolute stillness which characterized the affected side in this case, but have, on the contrary, a prolonged and sibilant expiration. In emphysema, also, the tympanitic resonance varies in intensity over different portions of the chest; displacement of the heart, if it occurs, is not excessive, and the character of the dyspnœa is not the same, being distinguished by the long and laborious expiration. In this case the dyspnœa was simply a shortness of the breath, without laborious expiration; it was constant, and aggravated by exertion, while in emphysema there is a paroxysmal tendency.

In seeking for the cause of this attack, we have for a guide only the patient's statement that the dyspnœa came on suddenly, while straining at stool, after suffering for three days with what was called pleuro-pneumonia. This indicated that the pleura, ulcerated or softened by inflammation, was ruptured by the effort of straining, allowing air to escape into the pleural cavity. It is quite possible that the patient's memory was not accurate as to the number of days which elapsed between the onset of the inflammation and the appearance of dyspnœa. The long persistence of the difficulty indicated that the orifice remained open, for, had it closed, the air in the pleural cavity must soon have been absorbed, allowing the lung to expand, and the heart to return to the left side. It is also evident that the orifice was valvular, allowing air enough to escape into the pleural sac during inspiration to keep up the tension, and preventing its return during expiration. This is the reason that amphoric respiration was not heard, there being no free communication between the lung and the pleural cavity. The lung remained collapsed about its root, allowing a very faint vesicular murmur to be heard at the level of the axilla.

No effusion was found at any time while the patient was under observation at the House of Mercy. Had this occurred, it would have been recognized at once by dulness at the base, changing its location with change of position, and by the presence of metallic tinkling. Whether or not effusion had occurred at any time during the previous two years cannot be positively determined. The physician who attended him in the initial attack discovered none, so the patient thinks, but another, now deceased, who subsequently treated him for a time, told him he had hydrothorax. It is possible to question the correctness of this diagnosis, for it sometimes happens that the intensely tympanitic resonance is mistaken for dulness, and this doubt is strengthened by the subsequent existence for three years of air without fluid. As the attack was evidently inflammatory at the outset, it is very remarkable if the pneumothorax was unaccompanied by effusion; but it is no less remarkable if effusion took place, and the fluid was subsequently absorbed, leaving the cavity full of air, but one or the other of these phenomena must have occurred.

Although hydro-pneumothorax is by no means uncommon, ninety per cent. of the cases resulting from tuberculous ulceration, simple pneumothorax is rare. Flint relates one case in his own experience, and refers to another reported by Gairdner. In both these cases there was a rupture of the pleura by the strain, without previous inflammation. In Flint's case, the strain was due to carrying a pack on the back, the patient being a peddler. Another case without effusion has been reported by Dr. F. C. Shattuck, resulting from a stab in the chest. This was reported at a meeting of the Boston Society for Medical Improvement, on December 8, 1884, on which occasion Dr. Lyman exhibited three cases of hydro-pneumothorax — one traumatic, the second phthisical, and the third of pleuritic origin.

The duration of this case is exceeded by one reported by Laennec, which persisted for six years, but, with this exception, exceeds any which I have been been able to find.

As regards the treatment of this case, there is but little to say, for it received very little. The medicines which were administered during the first few months he was in the hospital had no appreciable effect, and he afterwards took none but tonics. Every effort was made to improve his general health, and an exception to the rules of the house was made in his case by permitting him to remain for so long a time, in order that he might avoid work and exposure. The propriety of removing the effused air by paracentesis was considered at various times, but was not resorted to, because it was believed that removing the pressure from the lung would only tend to delay the healing of the orifice, and it was not thought worth while, for the sake of a very temporary relief, to postpone the recovery.

The position habitually assumed by the patient during the fifteen months prior to his recovery may have perhaps exerted some beneficial influence. As already mentioned, he occupied himself with acquiring the art of stenography, and, during these latter months, spent ten or twelve hours a day in writing. While so engaged, the left foot was placed upon a stool, which raised it about eight inches from the floor, and the left elbow rested on the left thigh. This position would tend to reduce the action of the respiratory muscles of the left chest to a minimum, and thereby prevent the forcible suction of air into the pleural sac. This would keep the valve of the pleural orifice at rest, and give its edges an opportunity to unite. The position was assumed by the patient because he found it very comfortable and restful, and very likely it answered the same purpose to some extent, as strapping the affected side, or fixing it with a plaster bandage, both of which have been recommended in such cases, the latter by Dr. F. T. Roberts, who has employed it with much benefit at the Brompton Consumptive Hospital.

REPORT OF PROGRESS IN ORTHOPEDIC SURGERY.[1]

BY E. H. BRADFORD, M.D., AND R. W. LOVETT, M.D.

DIRECT SURGICAL INTERFERENCE IN CERVICAL CARIES.[2]

Podres, in a case of severe cervical caries occurring in a child eleven years old, with evidence of deep abscess, made an incision two inches long, parallel to the posterior border of the sterno-cleido mastoid through the skin and fascia, and using a blunt instrument followed up the brachial plexus; pus was found on the sixth and seventh cervical vertebra, which were superficially ulcerated. The abscess wall and diseased bone were curetted and iodoform rubbed in, an antiseptic dressing applied with an extension for the head.

[1] Concluded from page 376.
[2] Centralblatt f. Chirurgie, No. 32, 1886.

After six months the patient had improved to a marked degree, but a fistula remained, which was dilated and the diseased bodies again curetted, after which the patient improved rapidly and remained at date apparently entirely well.

DEVIATION OF THE NASAL SEPTUM.[3]

This distortion is very common. Cozzolino found a straight septum only in twenty-one per cent. of all skulls examined. In a majority of cases the left cavity was narrowed by the projection of the septum. If the deviation is slight no trouble is occasioned, but in severe cases chronic rhinitis results. Correction can be effected by dilators, by ivory or hard-rubber plugs, worn for some time. Cotton tampons (in traumatic cases). Bony projections should, according to Hubert, be cut off by the galvano cautery, the turbinated bones partially separated from the septum and flattened down by cotton tampons and a specially devised compressor.[4]

INFECTIOUS OSTEOMYELITIS.[5]

Rodet claims to have identified the specific virus and demonstrated it by experiments on animals — injecting in the peritoneum, under the skin and in the veins — orange-colored coccus and osteomyelitis pus. Intra-venous injections gave the most marked results, causing two days after injection into the jugular, swellings in the different bones and joints, which on subsequent examination was found to be occasioned by a rarefying osteitis with suppuration, the formation of sequestra and in some instances separation of the epiphysis. The bones, as a rule, were the only tissues affected, though exceptionally the kidneys were found diseased. The bones most frequently affected were in the following order: the lower end of the femur, the upper end of the humerus of the femur and tibia.

SHOULDER-JOINT DISEASE.

The question of the treatment of this affection was discussed by Dr. Gibney before the New York Orthopædic Society. He first quotes from various authors to show the consensus of opinion as to the advisability of passive motion to the rigid joint either with or without the use of ether. He then relates two cases of false amchylosis after ostitis where restiffening took place after the application of force and where harm seemed to have been done. He closes by asserting that passive motion is not called for in chronic ostitis of the shoulder or chronic rheumatic periarthritis where the adhesions are extensive.[6]

SPINA BIFIDA.

The cure of a case of spina bifida by extirpation of the sac is described. There was a nut-sized tumor in the lumbar region, and although the child was two years old it had never walked and had double club-foot from spastic muscular contraction, as well as incontinence of urine and fæces. Tapping relieved these symptoms but caused inflammation of the sac, and a radical operation was decided on. The sac was slit and freed from its attachments around the hole in the vertebræ. It was sutured and put back into the canal and the transverse processes of the vertebræ opposite the cleft were broken, bent in, and sutured in the median line. The child recovered at once from its incontinence and its club-foot, and now runs about all day. The cicatrix is hard and firm.[7]

Morton[8] announces two more cures of spina bifida by his injection method. In one of them by Dr. Strain of Rio Janiero, three operations were necessary; at the third there was no fluid, and in fifteen months there was a firm cicatrix.

HOME-MADE APPARATUS FOR POTT'S DISEASE.

Under this title Dr. C. F. Taylor[9] describes a new and very cheap supporting brace which can be manufactured in any house and which accomplishes very much the same ends as the steel brace which bears his name. A piece of ordinary blotting-paper about the size and shape of the muslin part of a vest is impregnated with shellac and moulded, to the back of the patient. It dries and is removed and on it is built up a shell of alternate layers of linen prepared with glue and blotting-paper with shellac. The completed shell is light, firm, and very durable. Buckles are added and the apparatus is used with the ordinary Taylor apron. Its chief use will lie, of course, among people unable to afford a steel brace and in places where it is impossible to have access to a surgical instrument-maker.

ENGLISH ORTHOPEDICS.

A very good idea of the English orthopedic surgery of to-day may be gleaned by reading the article of Mr. Fisher[10] on that subject in the last volume of "Ashurst's International Encyclopædia." He first takes up the subject of club-foot, discusses its ætiology, and accepts the view that it is the result of a disordered nervous influence resulting in "a spastic muscular contraction." The treatment advised for all forms of club-foot is tenotomy followed by the use of the clumsy Scarpa's shoe. The author seems wholly ignorant of the existence of American ideas or American apparatus.

In the treatment of the deformities in rachitis he advises that manipulation should first be tried, to be followed by mechanical support and operation in the order named.

Lateral curvature is fully and clearly discussed, and the author expresses his belief in faulty positions as the ætiological factor in most cases. The first pathological change he believes to be in the ligaments and intervertebral discs. The treatment should be hygienic, gymnastic, and mechanical, for which purpose the very clumsy apparatus of Mr. Adams is advocated.

BONE DRAINAGE IN HIP JOINT DISEASE.

Mr. Stoker[11] comes forward as a very warm advocate of this method of treatment, originally proposed some twenty years ago by Kirkpatrick. His classification of hip disease is into three varieties, femoral, acetabular, and arthritic. He asserts his ability to diagnosticate between these three forms, and advocates the use of bone drainage only for the kind which begins in the femur. An incision is made down to the great trochanter, and a half inch trephine hole is bored as deep as the trephine will go. The site of the hole is at the lower anterior part of the exposed surface of the trochanter. He claims that such a pro-

ceeding is calculated to afford drainage and to remove the products of disintegration. He advocates the earliest possible operation, and considers rest to the limb as an important adjunct to the treatment. He would apply it as routine treatment to every case of femoral hip disease coming in his way, even after disintegration of the joint.

EXPERIMENTAL TUBERCULOSIS OF BONE.

Müller contributes some most interesting experimental results on the production of bone tuberculosis in animals. Starting with the assumption that the blood current was the channel of infection he injected tubercle bacilli into the femoral artery in sixteen rabbits; no available results followed. Then he repeated the injection, this time into the crural artery, from which the nutrient arteries of the bone arise. In ten rabbits killed from six to eight weeks later two showed localized tubercular disease, one a deposit in the marrow of the shaft, the other, miliary tubercles in the tibia and femur and a small cheesy deposit in the tibia. Next the nutrient artery was alone injected by means of a subcutaneous syringe needle. Two dogs, five sheep, and twenty goats were injected in this way. The dogs and sheep gave no positive results, whereas the goats were affected with bone lesions much like those in man. Alterations in the shafts of the bones were commonest; a circumscribed cheesy or granular deposit in the marrow or cortex, on more or less diffuse tubercular osteomyelitis with or without sequestration, also typical foci without perforation of the joint.

One goat lived fifteen months, the wound healed in eight days; in four months he began to limp, and swelling of the knee-joint began. After thirteen months he was killed and the knee showed a typical tubercular fungus disease of the joint, a large tubercular focus in the condyle of the femur, and a wedge-shaped sequestrum near it. There were also three other deposits in the lower end of the femur. Except in the popliteal glands no other tubercular deposit was found.

REPORT ON THE PROGRESS OF DERMATOLOGY.

BY G. H. TILDEN, M.D.
Physician to the City Hospital, Department of Diseases of the Skin.

SYMMETRICAL GANGRENE.[1]

THE forms of gangrene designated by the term "symmetrical" are to be considered as definite varieties of spontaneous gangrene. Spontaneous gangrene or necrosis of tissue due to internal, as distinguished from external causes, is dependent either upon pathological changes in the bloodvessels, upon disturbance of the nervous system, or upon defective constitution of the blood itself. The opinion of most authors is that so-called symmetrical gangrene is usually due to changes in the nervous system. The writer attempts to show, however, that although in most of these cases disturbance of the nervous system constitutes one factor in the production of gangrene, there occur instances in which some defect in the constitution of the blood can not be excluded as a cause. "Symmetrical gangrene," therefore, is to be regarded merely as a symptom which may be due to very different pathological conditions. Most of the concomitant symptoms in cases of "symmetrical gangrene" are caused by the pathological conditions which lie at the root of the matter, and this accounts for the various pictures presented by different examples of this disease. The writer groups the various possible causes of symmetrical gangrene as follows:

(1) Various disturbances in the general nutrition of the body. To this class belong those cases in which symmetrical gangrene appears after excessive bodily exertion, or in young persons of chlorotic and chloro-anæmic tendencies, or after chronic inflammatory processes and acute febrile infectious diseases.

(2) In not a few cases of symmetrical gangrene, hysteria is to be regarded as a cause.

(3) Symmetrical gangrene can also be a symptom of neuritis. Causes of the latter condition are injuries and "catching cold."

(4) Finally, disease of the brain and spinal cord may be the cause of the development of symmetrical gangrene.

Necrosis of tissue dependent upon temporary disturbance of nutrition or caused by acute neuritis, offer the best chances of recovery. Much more desperate is the outlook in those cases which are due to degenerative changes in some part of the nervous system.

The local treatment of tissues threatened or invaded by gangrene, consists in the application of dry warmth, electricity and irritating salves. After necrosis has been established it is to be treated on general surgical principles. The general treatment, of course, varies in each case, being determined by the pathological condition to which the gangrene is supposed to be due.

ACUTE MULTIPLE GANGRENE OF THE SKIN.

Doutrelepont[2] gives the account of an interesting and unique example of this affection. A strong and healthy unmarried girl, twenty-one years of age, who had never before suffered from any cutaneous disease, ran a needle under the nail of the left thumb, which was allowed to remain several days before being removed. On the day after the infliction of this injury there appeared the first symptoms of a subsequent and long-continued illness in the shape of small gangrenous spots in the skin. The back of the left hand was the first region affected in this way, but afterward the forearm and shoulder, then the upper arm and back, of the same side became also involved. It was a little over two months from the beginning of the disease before it overstepped in its distribution the middle line of the body. Within eight months from this time, however, the sacral region, the breast, the abdomen, both lower extremities and the right arm were all invaded by the gangrenous process which ultimately, over a year after it first appeared on the left hand, showed itself also on the face and head. During all this time the progress of the disease was not an uninterrupted one, but there occurred periods of a month or two, during which no cutaneous manifestations were developed. Each new outbreak of the eruption was generally preceded by an evening rise in temperature, which ceased only with the full development of the eruption.

The symptoms of the disease were as follows:

Either with or without the previous development of temporary cutaneous hyperæmia and with a sensation of painful pricking in the affected regions, there appeared oblong or rounded patches of a whitish-gray color and obscure contour, each patch being apparently composed of a group of smaller sized and rounded lesions. These patches varied from one to four centimetres in diameter, were not raised above the cutaneous level, and neither vesicles, papules nor pustules were ever developed in connection with them. Shortly after the appearance of these patches there was formed at their edges a line of demarkation separating them from normal skin, and surrounded in its turn by a narrow band of encircling hyperæmia. These gangrenous islets of skin then assumed a greenish-yellow color and were gradually cast off, leaving behind a shallow ulceration which presented small anæmic granulations and healed but slowly. Occasionally and more especially toward the end of the disease, healing took place underneath the necrosed tissue before the latter was cast off. The pathological process was confined to the skin, and at no time involved the subcutaneous tissues. Most of the cicatrices resulting from these losses of cutaneous tissue became keloidal, and it was only during the later periods of the affection that this tendency to the formation of false keloid disappeared. During the whole course of the malady, the patient, with the exception of the febrile attacks above mentioned, was in good general condition, the appetite and powers of digestion being unimpaired. The menses, however, were irregular and intermittent. Her only complaints were directed against the localized pains which preceded and accompanied the cutaneous manifestations and the chronicity of the latter. The sensitiveness of the skin and the tendon reflexes were always found to be normal, and there was never any enlargement of the lymphatic glands.

None of the various drugs administered, among which were arsenic, iron, salicylate of sodium, corrosive sublimate and quinine, appeared to have the slightest influence upon the course of the malady. The use of antipyrin, however, was found to control the evening rises of temperature, while the external application of a solution of corrosive sublimate $1\frac{0}{00}$ in strength, seemed to prevent the development of keloid, which did not take place after its use.

Examination of blood taken from these cutaneous lesions and cultivation experiments with the same and with bits of diseased tissue, demonstrated the absence of micro-organisms. Histological examination of portions of skin taken from the diseased regions, confirmed the clinical assumption that these cutaneous lesions, namely, the gangrenous patches, were composed of small, round efflorescences which were surrounded by normal skin. The initial pathological process was found to be an early stage of inflammatory vesicle formation, which by reason of quickly occurring cutaneous necrosis, did not reach a grade of development sufficient to render it clinically evident as such. These vesicles were always in circumscribed groups and were developed "en bloc," that is, all of the vesicles included in any given group were formed at once, there being no successive development of vesicles in any group. These are among the clinical characteristics of herpes, and the disease in this instance is regarded by the author as multiple, bilateral, and chronic herpes zoster, its full clinical development being prevented by the rapidity with which the gangrenous supervened upon the herpetic process, the case presenting many analogies with the variety of zoster described by Kaposi[3] as herpes zoster gangrenosus recedivus.

TROPHONEUROSES OF THE SKIN.

Kopp[4] gives the following conclusions as the result of a careful study of the "relations of the nervous system to diseases of the skin":

(1) It may be regarded as proven that the nervous system, under normal conditions, exercises a controling influence over the nutrition of the various tissues which go to make up the skin, and that organic and functional alteration of the central and peripheral nervous system may have, as a result, disturbance in the normal nutrition of tissue, irrespective of any vasomotor disturbance. Our knowledge with regard to the minute details of these processes is incomplete, but in general, it may be assumed that mere cessation of innervation gives rise to atrophic processes, while irritation of the nervous system is more apt to cause dysprophic processes in the tissues affected.

(2) Reasoning by analogy from processes of innervation, as exhibited in other parts of the nervous system, it is most probable that this trophic influence is exercised by certain ganglion cells, and groups of ganglion cells situated in the central nervous system, a normal condition of these cells being necessary to the normal production of nutrition. Nothing positive, however, is known concerning the exact situation of these trophic centres. Those which govern cutaneous

[4] Die Trophoneurosen der Haut, etc., von Dr. Carl Kopp. Wien., 1886, Verlag v. Wilhelm Braumüller.

nutrition are probably situated in the posterior regions of the spinal cord, although there is also some reason for assuming that they may exist in the ganglia of the posterior nerve-roots.

(3) There are not sufficient grounds for assuming the existence of special nerve fibres devoted to the transmission of trophic influence, and it is more probable that this peculiar influence is transmitted by means of the ordinary nerve-fibres.

(4) There are but few affections of the skin which can be regarded as uncomplicated trophoneuroses. There are hemiatrophia facialis progressiva, atrophia cutis circumscripta neurotica, possibly vitiligo, herpes zoster, pemphigus, scleroderma, and the anomalies of cutaneous secretion.

(5) Most of the other cutaneous affections usually regarded as trophoneurotic in origin are to be regarded rather as the result of several different processes, among which trophic disturbance plays a more or less important part. In general, as a consequence of disturbed trophic influence, is to be assumed a diminished capacity of tissues to resist insult and pathological changes; nevertheless, there also occur instances in which the trophic influence seems to be stimulated, and thereby the capacity for resistance and growth of tissue is temporarily, at least, increased.

(6) The essential reasons for the assumption of a trophic influence which resides in the nervous system are derived from clinical observation; efforts to induce uncomplicated trophoneurosis of tissue by means of experimental pathology have hitherto been fruitless, and anatomical knowledge with regard to the subject is scanty, and requires further investigation.

UNILATERAL CUTANEOUS PRURITUS OCCURRING AFTER EMBOLISM OF THE BRAIN.

Professor Köbner[5] exhibited in his clinic an unusual case, in which intense pruritus and complete anidrosis ensued after hemiplegia, caused by embolism of the brain. The pruritus and anidrosis were confined in their distribution to the left side of the body, which was paralyzed. The skin was entirely normal in appearance, showing no evidence of disease, except the mechanical injuries inflicted by the nails of the patient in her endeavors to relieve the itching, which was continual, and so severe as to deprive her of sleep.

Köbner said that he had never met with a similar case, either in his own experience or in literature, and confessed his inability to offer any satisfactory explanation. The usual causes of pruritus not due to pathological changes in the skin, that is, of so-called nervous origin, exist either in the skin itself, as in pruritus senilis, where, by reason of senile atrophy of the cutaneous tissues and glands, there ensues cutaneous irritation; or in the internal organs, such as disturbances in the female generative apparatus, and in the alimentary canal; or else in abnormal changes in the constitution of the blood, such as occurs more especially in cases of icterus, diabetes, and Bright's disease, where, by reason of the presence of foreign materials in the blood, there occurs irritation of the cutaneous nerves. Nothing of the kind was found to exist in this case, the skin being entirely normal, with the exception of the diminished secretion of the sweat-glands. The pruritus seemed to be due to trouble in the central nervous system, being somewhat analogous to those cases of general pruritus occasionally met with in connection with various forms of insanity. The treatment, which was found quite efficacious in modifying the violence of the pruritus in this instance, was the inunction, twice a day, of a salve composed as follows: chloral hydrat., camphor. trit. aa 5.00, and vaseline 50.00.

Clinical Memorandum.

TWO CASES OF OBSTETRIC INTEREST.

BY ALFRED HOSMER, M.D., OF WATERTOWN.

CAN UTERINE HÆMORRHAGE BE PRODUCED BY RENAL DISEASE?

MRS. —— died late in the month of January, 1886, at the age of fifty-seven. An autopsy was made within forty-eight hours. The external bulk of the heart was found to be very much increased. The walls were very thin, and the cavities much dilated. The muscular substance was tolerably firm. The kidneys were in the second stage of Bright's disease. The body of the uterus presented nothing very striking in its general form and size, or in the quality of its tissue. Its special abnormal features were as follows: the cervix showed considerable cicatrical tissue, and scarcely projected into the vagina. The os was a small circular opening, with quite a sharp edge, resembling a hole punched in a thin membrane. It did not represent the termination of a cylindrical canal, but rather the entrance into a cavity of very irregular shape. Two or three small patches of capillary hæmorrhage were found on the internal uterine surface. Within the wall of the organ, high up on the right side, there was a fibroid, measuring almost two cm. in diameter. There were also two very small subperitoneal fibroids low down near the cervix. The diseases of the heart and kidneys had been fully recognized before death; but the condition of the womb, with the exception of the loss of the vaginal cervix, had always been an unsolved question. This was due in part to the fact that the conformation of the patient rendered it absolutely impossible to obtain a satisfactory touch or exploration with the sound. Even firm pressure made upon the hypogastrium, failed to depress the uterus appreciably. The tonic conformation is not intended to suggest any pelvic deformity. Physically, the patient was a large woman, with decided tendency to corpulence; hence the difficulty of pelvic examination. Her circumstances were entirely comfortable. She had borne two children; the younger one a son, born in 1866. Through life she had suffered much from malarial disease, but otherwise had been pretty well. Menstruation had always been a regular function, and when it ceased is quite uncertain. In the early part of 1884, she had suffered for some time from severe pain in the lower portion of the trunk, and had also been subject to copious uterine flow. Her attendant, a female practitioner, advised that a trial of electricity be made in New York city. A very brief experience demonstrated the utter unfitness of that method of treatment, and it was abandoned. The patient then made her way to Philadelphia, where she placed herself under the care of an eminent gynæcologist. By him some operation was performed upon the cervix uteri. It is supposed to have been intended for the relief of an old laceration; although upon this point

no definite information was ever obtained. Having fairly recovered from the artificial illness produced by the operation, assurance was given that, with the exception of some cardiac trouble, she had no organic disease. Her haste to reach home probably induced her to depart somewhat prematurely, and thus to lose an advantage that might have been derived from medical supervision continued a little longer.

My personal acquaintance with the patient commenced with my professional attendance in April, 1884, and the latter continued, with some interruptions, until her death. There were two periods, one of six months, from August, 1884, until February, 1885, and one of five months, from March, 1885, until the following August, during which the patient made no request for medical advice. The history of the case, as I observed it, may be given as follows: Excepting the cardiac disease, which even then was well pronounced, I could discover in the patient, at the time of my early attendance, only an enfeebled condition, for which there seemed to be sufficient reason. Her mind was infected with the theory of "biliousness," and by unwise exertion she was striving to regain the strength she had lost. Before long she was overtaken by a uterine flow, which, together with its repetitions, formed such a puzzling subject of study during the remainder of her life. The interval which separated any two successive hæmorrhages varied from a few weeks to some months. Their duration was never short, and sometimes exceeded a fortnight. The attacks gradually became worse, and the worst of all was the last one, and came on about two months before death. The color of the blood was dark, as I observed it more than once through the speculum, while it issued from the os uteri in a stream of surprising size and velocity.

This recurring symptom of hæmorrhage was treated with rest and precaution, and all the various astringents that therapeutics can suggest, not omitting one of the latest remedies, the rhus aromaticus, of the efficiency of which, in certain cases, I am fully convinced.

As I look back upon the case, with a single glance at the whole of it, I am inclined to believe that, notwithstanding the faithful use of proper drugs by internal administration, the cessation of the hæmorrhage was due every time largely to the principle of self-limitation. Hæmostatics seemed to be false to their names, excepting as they were used locally. If a piece of alum or a wad of absorbent cotton saturated with alcohol were placed high in the vagina against the stump of the cervix, the flow would cease for a while, and be essentially modified for two, three or four days. If during a free hæmorrhage the uterine cavity were wiped out with alcohol, or a small quantity of the liquid were injected into it, the stream of blood would cease for some minutes. There was another effect produced by the alcohol placed in the vagina, and which deserves notice. The passage was contracted and puckered as by an astringent; so that a speculum which was introduced with perfect ease before the use of the alcohol, was inadmissible afterwards. In her latter days the patient suffered extremely from the characteristic nausea and vomiting, and from neuralgia, in the form of severe hemicrania.

I have selected a question for the title of this communication for two reasons: (1) The hæmorrhage was largely in excess of anything that could be expected from, or explained by, the pathological changes found in the uterus. (2) Certain it is that, associated with renal disease, there may be changes in the vascular walls which allow and determine serious hæmorrhages in the cerebral tissue, and copious, even dangerous, epistaxis. May not similar results be observed in other portions of the system?

A FATAL CASE OF URÆMIC CONVULSIONS, OCCURRING AT THE SEVENTH MONTH OF PREGNANCY; THE PATIENT DYING UNDELIVERED.

Late one evening, by a message which failed to imply any urgency, I was summoned to a stranger, then a guest at the house of her sister, and intending to return home on the following day. The case was reported to me as one of indigestion, produced by an apple that had been eaten in the afternoon. Her family had not the least suspicion of the crisis that was rapidly approaching. A very brief inquiry discovered pregnancy in a primipara advanced to the seventh month; headache, defective vision, general œdema, and severe gastralgia. Of course nothing was known of the method of the renal function. The statement that convulsions would soon occur caused much surprise. A nurse was ordered, a full dose of bromide and chloral was administered, but the necessary preparations for the treatment of a grave case were hardly completed when the patient had her first seizure, and that was very far from being a slight one. This was just twenty-six hours before her death. During the first fourteen hours of this period, she had seventeen convulsions; the remainder of the time she lay in a state of complete unconsciousness. Immediately after the first fit I drew the urine, and this was almost at midnight. Although in its general appearance, this urine looked sufficiently well, it contained a large proportion of albumen. During the next six hours, that is, until six o'clock, the quantity of urine secreted was just about one-half of what it ought to have been, and the degree of albuminuria was increased. During the next period of six hours, terminating at noon, the renal function seemed to undergo an almost complete abolition. The urine was extremely small in quantity, and as thick and turbid as chocolate. This brief account includes all the essential features of the case, so far as concerns the course of the disease, and its modes of manifestation. Before detailing the treatment, it should be stated that uterine action existed only as it was induced. There was no sign of spontaneous labor. Bromide and chloral showing no good results, morphine, used subcutaneously, was substituted, with ether upon the approach of a fit. Still later the ether was used by itself, and with great freedom and persistency. When the kidneys were found to have failed so signally in their function, jaborandi was administered by the rectum. It very promptly produced copious diaphoresis, but had not the slightest diuretic effect.

Very soon after assuming the care of the case, and in view of its unusual severity, I attempted, but unsuccessfully, by the method of digital dilatation, to produce labor and to effect delivery. The difficulty reminded me of what I have encountered in the case of tonic spasm of the internal os, and may have depended upon the fact that the cervix, which includes the os, was not in that ripe and mature condition that commonly requires nine months for its full development. My efforts at dilatation covered a period of many

hours; they were hopeful and persevering, and sufficiently energetic. All I accomplished was to force into the os, at once, the fore, middle and third fingers, and not even these in their entire length. When they were finally withdrawn, they were marked with a sharp circular indentation, such as would have been produced by a string tightly drawn. As an adjuvant to this mechanical treatment, a useless attempt was made to soften and relax the unyielding tissue of the obstinate cervix, by throwing upon it a stream of tepid water. At a late stage the difficulty of dilatation was much increased by the condition of the vagina, which became so dry, so hot, and so swollen as to almost refuse admission to the hand.

As a result of the change enforced in the cervix and os, uterine action came on, and the contractions in their force and regularity, were quite satisfactory for a time. For the purpose of maintaining them ergot was used by the rectum. The moribund stage was of unusual length, and many hours before death it became necessary to confess, for this case, the insufficiency of the obstetric art.

Reports of Societies.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M.D., SECRETARY.

JUNE 12, 1886, the President, DR. A. D. SINCLAIR, in the chair.

DR. HOSMER reported two cases,[1] the first bearing upon the question,

CAN UTERINE HÆMORRHAGE BE PRODUCED BY RENAL DISEASE?

DR. STRONG thought the uterine hæmorrhage was more likely due to the dilated condition of the heart and the consequent passive congestions, than to the kidney: the uterine mucosa becoming hyperæmic, moderate hæmorrhage is the frequent result.

DR. RICHARDSON had noticed that there was more flowing *post partum* in women affected with Bright's disease.

DR. L. R. STONE had also observed the phenomenon.

DR. HOSMER said there was no constitutional cause for the hæmorrhage in his case, that he had discovered. He then reported

A FATAL CASE OF URÆMIC CONVULSIONS OCCURRING AT THE SEVENTH MONTH OF PREGNANCY, THE PATIENT DYING UNDELIVERED.

DR. BLAKE said that in such cases he induced profound anæsthesia with ether, and dilated the cervix with the fingers and delivered: he did not believe in the use of morphia.

DR. SINCLAIR agreed with Dr. Blake, and had never failed in following the method of digital dilatation under surgical anæsthesia. In some cases he would also give calomel and jalap; and would use emollients, when the vagina was hot and dry. He never gave morphia.

DR. HODGDON thought chloroform the best anæsthetic, because it acted more quickly.

DR. C. H. COOK advocated free catharsis.

[1] See page 402 of the Journal.

DR. A. H. JOHNSON spoke of the case of a patient affected with nephritis, who, when near full term, was seized with headache and epigastric pain. Labor soon set in and speedy delivery followed: she then had a convulsion. He used no ether, but gave chloral and bromides, and also a quarter of a grain of morphia. There was no subsequent convulsion. He had carefully considered the question of using morphia in Bright's disease, and was in favor of its use: morphia was said to increase the secretion of urine.

DR. F. W. GOSS was interested in the rapid increase of the renal affection: he had seen cases in which the morbid changes were very rapid.

DR. RICHARDSON spoke of the propriety of bleeding in cases of eclampsia: he had bled in but one case. Dr. Fordyce Barker approved this treatment, however, and bled very frequently. In the cases of post-partum eclampsia which he had seen, he had noticed that there was a greater amount of flowing, and this would of course make further bleeding unnecessary.

DR. INGALLS, in a case of post-partum eclampsia, had bled the patient, and she had but two convulsions afterwards, and recovered: he noticed no undue flowing.

DR. WELLINGTON had seen two cases of hæmorrhage after convulsions.

QUARTERLY MEETING OF THE ESSEX NORTH DISTRICT MEDICAL SOCIETY.

MAURICE D. CLARKE, CORRESPONDING SECRETARY.

THE quarterly meeting of this Society was held at the Brown Square Hotel, Newburyport, October 6th, the President, DR. E. P. HURD, of Newburyport, in the Chair.

The records of the last meeting were read by the Secretary, DR. GEORGE W. SNOW, of Newburyport, and approved.

By invitation, DR. S. K. TOWLE, formerly of Haverhill, but now surgeon at the Soldier's Home, Hampton, Va., addressed the Fellows. He said, among other things, that he missed, in his present practice, the quacks. All his chronic and incurable cases remained with him, and did not give him a desired rest by betaking themselves, as was their habit in private practice, to the quacks. He humorously deprecated, therefore, a possible subsidence of quackery for the sake of the profession.

After a brief discussion upon various phases of the fashionable quackery of the day, DR. A. STABLER, of Lawrence, read the paper of the session, upon

A NEW PORTABLE BATTERY, AND SOME DETAILS OF ITS APPLICATION.

DR. STABLER exhibited a very ingeniously constructed battery of his own devising, and made some remarks upon electro-therapeutics, citing illustrative cases from his own experience, especially in the field of gynæcology. Dr. Stabler's paper was succeeded by a general discussion upon the use of electricity in medicine, and later, upon a variety of subjects.

DR. ENOCH CROSS, of Newburyport, the oldest member of Essex North, now eighty-six years old, and retired from the practice of medicine, was introduced to the Fellows present, and made a few remarks expressive of his gratification at meeting them again.

DR. EDWIN WARREN BULLOCK, of Haverhill, and

DR. ARTHUR AMBROSE SWEENEY, of Lawrence, passed the requisite examination, and were admitted as Fellows of the Society.

Voted, to hold the next meeting at Haverhill, on the first Wednesday in January, and, after dinner, adjourned.

THE NEW YORK ACADEMY OF MEDICINE. SECTION IN NEUROLOGY.

STATED meeting, October 8, 1886.

JULIUS ALTHAUS, M.D., M.R.C.P., of London, read a paper on

SOME POINTS IN THE PATHOLOGY AND TREATMENT OF PARAPLEGIA DEPENDENT ON POTT'S DISEASE,

in which he first gave the detailed history of a case. The patient was a florid-looking girl of twenty, who was employed as a domestic. She had enjoyed good health from early childhood. She had never had any scrofulous trouble, and there was no phthisis in her family. Moreover, so far as she knew, she had never received any injury to the spine. Two years before she came under observation she suffered from an attack of rheumatic fever; but, on recovering from this, she went back to service. Nine months later, however, she began to suffer from severe pain in the right foot, which was soon followed by marked loss of power in the right leg. Eventually this was followed by pain and paralysis in the left leg also. She then became confined to bed, and for a considerable time was treated in a provincial hospital, without any benefit.

When she came under Dr. Althaus's care an examination showed that there was almost complete paralysis from the hip-joint down, on the right side, and less marked paralysis in the left limb. On applying the faradic and galvanic currents, responses were obtained with unusual facility. The superficial reflexes were also unusually brisk; and the same was true of the deeper reflexes, as well. There was no history whatever of spontaneous cramps or of muscular rigidity. There was more or less coldness, lividity and clamminess about the foot and instep. The different forms of sensation in the entire limb were perfectly normal. The left side was in all respects less seriously affected than the right.

A distinct prominence of two of the dorsal vertebræ was clearly recognizable. There was no pain in the spine, and no increase of temperature; but the mobility of the spinal cord was much impaired. The commencement of the deformity, it was ascertained, had been coincident with that of the pain and paralysis fifteen months before. It seemed evident that there was more or less thickening of the spinal dura mater, and that in the cord itself there was interstitial myelitis present. The posterior columns were also implicated, as shown by the neuralgia that had existed for so long; but it was probable that the central portion of the cord still remained normal. She was placed on the iodide of potassium and cod-liver oil, with complete rest, and frictions with liniments, etc.; but at the end of three months no improvement whatever was noted.

At the request of Dr. Althaus, Mr. A. Pearce Gould then made an application of the actual cautery to the side of the spine, and within a few days the patient was perceptibly better. The application was made four times in all, and she continued to rapidly improve. In a short time she was able to walk as well as ever, and the vaso-motor disturbances, shown by the coldness, lividity and perspiration about the ankle, disappeared. The patient was then discharged practically cured, and entered a convalescent home for a time.

Patients suffering from paralysis due to Pott's disease, Dr. Althaus went on to say, had sometimes recovered by the opening of an abscess, and it could not be doubted that the powerful counter-irritation resorted to in this instance had brought about a cure by its effect upon the diseased structures involved. While the pain in the foot and leg had been very marked, there had never been any pain in the back. The former appeared to have resembled the lightning pains of locomotor ataxia. He believed that this pain was due, not to pressure on nerves or inflammation of the dura mater, but to irritation of the posterior columns of the spinal cord. The symptoms of coldness, lividity and perspiration of the foot and instep, showed that there was present some degree of vaso-motor paralysis, and it was plainly caused by central disturbance.

Formerly, it was supposed that paralysis occurring in Pott's disease was due to an actual destruction of the substance of the spinal cord; but if this were the case, recovery, which is so often noted, would be impossible. In many cases, however, the entire cord suffered some amount of pressure, which gave rise to paralysis. Vulpian had shown by experiments on animals that paraplegia could be produced and removed at will by setting up and withdrawing pressure upon the cord; the paralysis being motor in character, with no loss of sensation. But this simple form of paralysis was not all. Charcot and others had shown that there was habitually inflammation of the external layers of the spinal cord. Interstitial myelitis seemed to be always present also. In the case related there could be little doubt that the coarser pyramidal fibres were affected by either myelitis or degeneration, probably the former.

How, continued Dr. Althaus, shall we explain the fact that while there was almost complete motor paralysis, especially on the right side, there was no loss of sensibility? This was a point which had not been hitherto satisfactorily accounted for, and was worthy of careful study. There were three different degrees of pressure upon the cord met with in Pott's disease. In the first there was no pressure exerted upon the actual structures themselves; and all had seen cases in which, while there was considerable deformity, there was no paralysis. The reason for this was, that the pressure was just sufficient to displace the spinal fluid, but it did not extend to the cord itself.

The second degree was that which existed in the case under consideration. Here there was not only displacement of the spinal fluid, but also interstitial myelitis. In those cases of paralysis resulting from Pott's disease, motion was more easily lost than sensation. There was not a single case of the disease on record in which there had been paralysis of sensation without that of motion; while we constantly meet with the reverse of this, paralysis of motion without that of sensation.

The third degree was met with in those cases in which we had to do with complete transverse mye-

litis, implicating not only the columns, but the gray matter of the centre of the cord as well. In connection with this there was found anæsthesia and analgesia, with paralysis of the bladder and rectum and a tendency to bed-sores. In such cases, on account of the profound organic changes which had resulted from the pressure, recovery was impossible. It was important, therefore, that we should resort to the actual cautery at an early period in cases of Pott's disease in which paralysis results, in order to prevent the pathological process in the cord from going on to this advanced stage.

The conclusion of the paper was devoted to some consideration of the actual cautery. Having referred to its history in the past, Dr. Althaus said that personally he now never thought of resorting to it in spastic spinal paralysis, tabes dorsalis, or other disease of the cord proper; but that he had always found it of the greatest service in disease of the membranes.

DR. V. P. GIBNEY said that he had been much pleased with the clinical picture which the distinguished writer had presented, and also with the admirable manner in which he had connected the various symptoms with the pathological conditions present in the case, which was one of great interest. As to the actual cautery, this was not the only means at our command for securing relief to the patient. He had seen a large number of similar cases perfectly relieved within a week, by the simple application of a jury-mast. Some time ago, Dr. Charles J. Poore read a paper in which he related a number of cases in which he was able to report very good results in the treatment of Pott's disease, by the actual cautery. Afterwards, however, he was much disappointed in its use, as the results in other cases were entirely unsatisfactory.

The author of the paper had cited but a single case, and though, in this particular instance, the method was completely efficient, he did not think this was enough to prove it applicable in general. Personally, he believed that the actual cautery was objectionable, and particularly in the case of children. Although it was the present custom to use it very lightly, it was impossible to persuade patients that it would not hurt, and both the mothers and the children objected very strongly to its use. Of course, this objection applied principally to private practice. He thought that, as Dr. Althaus had pointed out, the cases which improved did not belong to the third stage. He had a number of times applied the actual cautery when the very first symptoms of paralysis appeared, however, but without securing any good resuls. When, on the other hand, he had stopped its use, and had resorted to suspension and the application of a jacket, the patients got well. In these cases he was strongly in favor of giving large doses of iodide of potassium — sixty, seventy, or eighty grains, three times a day. The objections to the use of the iodide in adults did not hold good in regard to children, with whom it almost always agreed perfectly, and who often grew fat upon it. With the iodide, and a good jacket to support the spine, he had obtained better results than in employing any other treatment.

DR. SACHS said that he agreed with the author of the paper that interference with motion was much more common than with sensibility. With regard to the treatment, he had no doubt that the actual cautery was efficient in certain cases, and yet in the one related by Dr. Althaus, he was inclined to doubt whether the credit for the cure should be given to this procedure entirely. Thus, in addition, the patient was given complete rest, and treated with cod-liver oil and other tonics. He had seen some cases cured by complete rest alone. The same was true of many cases of chronic myelitis, and he called to mind particularly one case of post-puerperal paraplegia. He did not wish to discredit the treatment of the actual cautery, but it seemed to him that the other measures adopted were of considerable importance in bringing about the satisfactory result noted.

The Chairman, Dr. L. PUTZEL, said he had had a few cases, in which the results were similar to those obtained by Dr. Althaus in the case reported in the paper. In these instances, the improvement was so rapid after the application of the actual cautery, that no reasonable doubt could be entertained as to its efficient agency. In the large number of cases, however, this procedure was entirely without beneficial results. As to large doses of iodide of potassium, as recommended by Dr. Gibney last year, he had found, in his experience, that these also were without effect. He agreed with the last speaker that, after all, time and rest were the most successful remedies. Good feeding, however, was a matter of great importance also. With regard to the absence of anæsthesia in these cases, it seemed to him that the explanation presented in the paper was a very plausible one. It certainly seemed to him to be a fact that there was some quality about sensory fibre which made it resist pressure much more efficiently than motor fibre.

In closing the discussion, DR. ALTHAUS said that the good effect produced by very large doses of iodide of potassium, as claimed by Dr. Gibney, was a very interesting matter, and that on his return to England, it would give him great pleasure to practically test the efficacy of the treatment. It had been assumed that the rest and other treatment, beside the application of the actual cautery, had had much to do with securing the good results noted in the case which he had narrated. But this he believed to be a mistake. For four months in the provincial hospital, and for three months after she came under his own care, the patient had been treated with complete rest in bed, and, in addition, she had been taking cod-liver oil and iodide of potassium, the latter in thirty-grain doses, three times a day. And yet no effect whatever was produced — the patient remained precisely in the same condition. As soon, however, as the first application of the actual cautery was made, a marked improvement in the paralysis commenced, and this rapidly became more and more marked under the repeated use of the cautery. Before resorting to this measure, he had wished to give the rest treatment a thorough test, and as it was attended with no improvement, while from the first the improvement was positive under the use of the cautery, he thought he was fully justified in attributing the cure to this particular agent. There was, no doubt, cases in which the cautery had failed, but it seemed to him that in these instances the disease was probably more advanced. He would like to inquire if there was not some loss of sensibility, as well as motion, in such cases. In conclusion, he said that his reason for bringing this subject before the Section was to induce surgeons to resort to the actual cautery at as early a period as possible.

Dr. Graeme M. Hammond read a paper on

ATHETOSIS, WITH REMARKS ON ITS PATHOLOGY.

In speaking of the treatment, he said that this affection, being dependent on certain irremediable organic changes in the brain, it was impossible even to produce a cure. At the same time, there were certain measures which, in some instances at least, had been attended with marked relief, and sometimes had succeeded in abolishing all symptoms of the trouble for a considerable period. He referred in detail to four cases, one of which, reported by Gowers in 1876, had been treated with galvanism, and the remaining three of which had been treated by nerve-stretching. The most interesting of these was the original case of Dr. Wm. A. Hammond, upon which his description of the disease (which is mainly characterized by an inability to retain the fingers and toes in any position in which they may be placed, and by their continual motion), published in 1871, was based. This patient was also a confirmed epileptic. In 1882 Dr. G. M. Hammond stretched the median nerve very forcibly; after which both the epilepsy and athetosis disappeared for three months. At the end of five months, however, they were as bad as ever. At the time of the operation the nerve was in an apparently perfectly healthy condition. In 1884 the same operation was repeated, and the nerve still appeared normal. After this the patient remained well for about four months, but in eight months was again as bad as ever.

In 1885 the operation was again repeated, and this time the nerve appeared to have lost its healthy character, and after the stretching, instead of promptly rebounding to its position, it hung in a loop outside the wound. The result of the operation, however, has been more satisfactory than either of the others. A year and four months has now elapsed since it was performed, and there has been no return whatever of the athetoid symptoms: the muscles of the hand, arm and foot all being perfectly under the perfect control of the will. The patient, however, still has an occasional epileptic seizure (perhaps once a month), and he is the subject of that interesting feature sometimes characterizing epilepsy, double consciousness. This state of oblivion respecting former events sometimes lasts for four days at a time.

Dr. Hammond said that he believed that nerve-stretching yielded better results than electricity or any other method of treatment in athetosis. He was unable to say precisely how stretching of the median nerve in the arm affected the leg also; but such appeared to be the fact. Such a procedure could, of course, have no effect on the organic changes in the brain giving rise to the athetosis; but he thought that it might perhaps have some effect upon the *corpus striatum*. Dr. Dana had shown that stretching of the sciatic nerve actually stretched the spinal cord as high up as the cervical vertebræ.

Dr. Hammond was able to present the reports of nine autopsies, made by various neurological authorities, in cases in which athetosis had been present during life. In three of these there were well-marked lesions of the corpus striatum, in three, of the optic thalamus, in one or more, of both the corpus striatum and optic thalamus, and in two, of the cortex cerebri. He also referred to a number of authentic autopsies in cases of allied affections, in which the same portions of the brain were the seat of organic disease. His conclusion was, that athetosis and allied affections are due to lesions of the corpus striatum, optic thalamus, and cortex cerebri, and of these parts alone.

Dr. Birdsall said that in order to show that athetosis and allied clonic movements were dependent alone on lesions of the gray matter of the brain, it was necessary to prove that in the condition found at the autopsies referred to the internal capsule was not at all implicated. Athetosis so frequently followed hemiplegia, and especially in children, that it seemed reasonable to suppose that the motor fibres were affected in it.

Dr. Putzel mentioned two autopsies he had seen which bore upon the subject, and which seemed to confirm the position taken by the author of the paper. One was in a very marked case of chorea, of twenty years standing, and the autopsy revealed pronounced atrophy of the central convolutions, with descending degeneration down the cord. The other was in a case of pre-hemiplegic chorea. He was glad to find that the author of the paper had not treated athetosis as a distinct disease, but as an affection allied to chorea, hemi-chorea, etc.

Dr. Hammond explained that the greater number of the autopsies referred to were described with the greatest accuracy, many of them being accompanied with diagrams representing the seat of disease, and that in none of them were motor fibres implicated in the slightest degree.

Recent Literature.

Handbook for the Instruction of Attendants on the Insane. Prepared by a sub-committee of the British Medico-Psychological Society. Boston: Cupples, Upham & Co. pp. 137. 1886.

How to Care for the Insane. A Manual for attendants in Insane Asylums, by William D. Granger, M.D., first Assistant Physician, Buffalo Asylum for the Insane, N. Y. New York and London: G. P. Putnam's Sons. pp. 96. 1886.

If the knowledge and treatment of diseases of the mind had kept pace with that of bodily disorders, the systematic instruction of attendants by special training and by manuals, would have long since been inaugurated. The advance in the care and treatment of the insane has, to be sure, been rapid since the days of Pinel and Conolly, but the early years of ignorance and neglect in this direction remain to be compensated for, before the gains in other branches of medicine can be counterbalanced, and diseases of mind and body placed upon an equal therapeutic footing.

The books before us are nevertheless welcome as harbingers, though late ones, of a happier lot for the insane through the thorough instruction of those upon whom their well-being so largely depends.

The Handbook for the Instruction of Attendants is an attractive reprint from the English publication, a systematically arranged and useful manual. A good deal of ground is covered, including not only the care of the insane, general duties of the attendants and nursing of the sick, but considerable mental and bodily physiology and pathology necessarily of a most elementary kind.

"How to Care for the Insane," goes over the

same ground but in more detail, and though the style is of the plainest, the matter is particularly clear and readable, and well calculated to attract and hold an attendant's interest. Exception must be taken, however, to the introduction of matters purely of asylum administration, such as whether patients shall "sleep in large dormitories or move about in big parties."

There is much in these manuals relating to psychology and physiology that might be omitted. Attendants care most for and remember best the instructions which immediately relate to the details of the care and management of their charges. This information when clearly and fully presented, they read with profit and an eagerness which shows how great has been the need of it. But as we question how far the average hospital nurse is guided in her duties by a knowledge of physiology and pathology, we decidedly doubt the ability of attendants, particularly those in our large public asylums, to understand, to properly apply and to remember the chapters on the nervous system, and mental processes and states in health and disease. This applies with less force to those who have the advantages of special instruction, as in the pioneer training schools of the McLean and Buffalo Asylums.

Advice about dealing with that most difficult class, hysterical patients, of which every asylum has its representatives, might well find a place among instructions to attendants.

Nevertheless, taken as they are, these manuals ought to be carefully read, not only by attendants everywhere, but by nurses generally. A suitable book of this sort might be profitably recommended to nurses in general training schools, so frequently does it happen that nurses without any experience in such cases are put in charge of insane patients at their homes.

The Sixth Massachusetts Health Supplement.[1]

We are glad to receive the last health supplement to a report of a board of health, lunacy and charity. It embraces the following topics: "Malaria in Eastern Massachusetts," by Dr. Z. B. Adams, of Framingham. "Weekly Mortality Reports of Cities and Towns, for 1885." "Report upon Food and Drug Inspection." "Disposal of Sewage at Massachusetts Reformatory," by Wm. Wheeler, C. E. "Case of Lead Poisoning," by Dr. F. W. Jones. "Reports of Water Boards and Companies." "General Index of Health Supplements and Chapters on Public Health in Annual Reports."

Nearly two hundred cases of intermittent fever, generally tertian, rarely quotidian, more rarely still quartan, were observed in Framingham during the summer of 1885. The course of the disease and the surrounding conditions are described in a paper on this same subject read by Dr. Adams before the Massachusetts Medical Society and published in this JOURNAL, (vol. cxv, p. 173.)

For nine years the three factors of heat, moisture, and vegetable decay were present in the greatest activity in Framingham, while none, or rare and doubtful, cases of intermittent fever have arisen, until 1885; and then during an epidemic of the disease, few, if any, cases appeared in the vicinity of the great reservoirs and dams, where the three factors had been present in the highest degree.

Dr. Adams gives, appended to his paper, a very useful tabular statement of outbreaks of malarial fever in New England.

Under the law providing for the inspection of food and drugs, from January 1, 1885, to May 31, 1886, there were examined 6,029 samples of food, of which 2,433 were found adulterated or not conforming to the statutes; 3,664 of milk, of which 1,463 were below the standard; 1,607 of drugs, of which 729 were adulterated. Warning notices to retailers were sent in 1,031 cases. The number of prosecutions conducted and complaints entered were for milk 68, butter 32, other articles of food 18, drugs 1.

The disposal of sewage at the Concord Reformatory by irrigation is described; a case of lead poisoning is reported; a chemical examination of 88 specimens of wall-paper showed 34 to contain much arsenic; 9 considerable, and 17 a trace; sixty-six pages are devoted to a statement of statistical returns of water-boards required by law, but most of which has its chief value to persons interested in water companies rather than to sanitarians.

As we have often felt it our duty to differ with the executive of the State, and the Legislature, in the struggle to separate the board of health from its lunatic and charity combination, we take great pleasure in giving Governor Robinson the highest praise for his recommendations to the Legislature in the matter, and especially for the high character of the new board of health which he has appointed.

[1] Seventh Annual Report of the State Board of Health, Lunacy, and Charity of Massachusetts. Supplement containing the Reports and Papers on Public Health, with a General Index. Boston: Wright & Potter. 1886.

— Sir Andrew Clarke, the celebrated English physician, is reported to have declared that one-half the population of London is permanently ill. He defines health as "that state in which the body is not consciously present to us; the state in which work is easy, and duty not over great a trial; the state in which it is a joy to see, to think, to feel, and to be." With such a definition of health, we suspect that his statement is well within bounds.

— "'Pears to me," said old Uncle Pete, as he leaned his hoe against the corn-crib and abstracted a pebble from his shoe, "'pears to me like dar war some kin' o' misdecomposishum in all dis talk about babies cuttin' teef. De way I'se cum to look at it, hit's de teef cuttin' de baby. Leas'wise dat's de way hit looks in de case ob culled chilen." — *Archives of Pediatrics.*

— The *Northwestern Lancet* says: Last year an attempt at the cultivation of opium was made at New Ulm, Minnesota, by Mr. Emil Heschke. Several kinds of poppies were experimented with, and specimens of the *Papaver somniferum* were raised, whose unripe capsules yielded opium containing fifteen and two-tenths per cent. of morphine. The Pharmacopœia requires that opium shall contain ten per cent. of morphine, so that the Minnesota production came fully up to the standard. But, for some reason, it was concluded that the production of opium would not be profitable, and it is not likely that this industry will be added to the resources of that State, at least at present.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, OCTOBER 28, 1886.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

PERFORATING INFLAMMATION OF THE VERMIFORM APPENDIX.

IT is not always easy to know just what advantage there may be in the publication of cases which present no very unusual features or new facts in pathology or therapeutics, though the cases are just unusual enough to occur but once or twice in the lifetime of a practitioner. But occasionally there appears a man who gathers together the clinical reports of such isolated cases and tabulates and analyses and studies them in connection with his own experience till he succeeds in showing the natural history of the somewhat rare affection, points out the particular direction in which danger lies and the proper method of interference.

A noteworthy example of such a study is to be found in a paper read at the Association of American Physicians at its first annual meeting at Washington, June last, in which Dr. R. H. Fitz discusses the perforating inflammation of the vermiform appendix with special reference to its early diagnosis and treatment, and published as the leading article of the October number of the *American Journal of Medical Sciences*. It is by no means easy to condense into the space these columns afford an article which is at once long and remarkable for the absence of superfluous words; but we wish to give our readers the results of Dr. Fitz's conclusions and at the same time to illustrate the advantage of reporting unusual cases with care.

Recognizing the lack of agreement in the use of the terms typhlitis and perityphlitis, Dr. Fitz has made a collection of 257 cases of perforating inflammation of the appendix. By limiting the attention to the essential features of these cases it was thought possible to recognize the characteristics of this sharply defined affection, by means of which it might be differentiated from all others occurring in this region. At the same time 209 cases of typhlitis and perityphlitis have been collected.

From the consideration of these cases it is apparent that perforating appendicitis is a disease most frequently occurring among healthy youths and young adults, especially males, and that attacks of indigestion and acts of violence, particularly from lifting, jumping and falling are exciting causes in one-fifth of the cases. A local cause is to be found in more than three-fifths of the cases in the retention in the appendix of more or less inspissated fæces, or in the presence there of a foreign body. The retention of fæces may be promoted by a constipated habit, but congenital or acquired irregularities in the position and attachments of the appendix frequently act as favoring causes. A fact in support of the last-mentioned statement is to be found in the frequency of successive attacks of inflammation of the appendix.

The course and results of the inflammatory process show extreme variations. A simple catarrhal appendicitis is to be recognized anatomically but its clinical appreciation is doubtful. This appendicitis may progress toward ulceration, even to a peritonitis which may result fatally, an event not unlikely in the presence of a foreign body. When the peritonitis represents the extension of the inflammation through the walls without perforation, adhesions will take place; when the appendicular peritonitis is associated with necrosis of the wall the inflammation of the peritoneal coat tends to become diffused and productive of serous and cellular exudations. The adherence of coils of intestine to each other and to the abdominal wall favors the accumulation of the exudation in a limited space and thus the formation of the tumor. At this stage the anatomical condition is a circumscribed peritonitis.

The peritoneal abscess may become absorbed or its contents may escape into the general peritoneal cavity through ruptured or softened adhesions, when as a rule death rapidly follows; or the tumor may suddenly diminish in size with the discharge of pus from a hollow organ, as the intestine, bladder or vagina. The anterior abdominal wall may be perforated and a sinus be established opening in the groin, lumbar region or at the umbilicus. The more protracted the course of the disease the greater is the probability of the destruction of the peritoneum which forms the wall of the abscess.

With the perforation of the parietal peritoneum may occur extensive necrosis, with purulent and fæcal infiltration of the abdominal walls. The primary appendicular peritonitis may in like manner be continued into the tissues behind the cæcum and thus a paratyphlitis or perityphlitic abscess be occasioned. So various are these possibilities that every case of so-called perityphlitic abscess must be regarded as primarily one of perforating appendicitis unless proven to be the contrary. The results of post-mortem examinations show that the attacks of inflammation of the appendix frequently occur without giving rise to characteristic symptoms. The latency of the symptoms in certain cases is such that the eventual diagnosis is obscured and the desirable method of treatment postponed. There can be but little doubt that a diag-

nosis of bilious attack, colic, gastritis, enteritis, gravel, ovaritis, congestion of the womb and the like may not unfrequently conceal the existence of an inflamed appendix.

Sudden severe abdominal pain is the most constant decided initial symptom of perforating appendicitis. Sometimes it follows an attack of diarrhœa. It is usually intense and is occasionally accompanied by a chill, or nausea and vomiting. Though usually limited to the fossa the pain sometimes extends upward as far as the liver or downward to the rectum, testicle, perineum or thigh. Great nervous anxiety, followed by a temporary prostration, is occasionally associated with the attack. This sudden intense pain is probably due not to the actual beginning of the disease but to the separation of the fresh adhesions of an acute appendicitis, and often, perhaps usually, to the perforation of the inflamed appendix. It generally represents the beginning of a more extensive peritonitis.

The abdominal pain is followed by fever as the next constant symptom. The temperature is rarely very high and the accompanying constitutional disturbances are frequently slight if not absent. During the first three days following the outset of the pain micturition is occasionally disturbed, and the use of the catheter may be necessary. The abundant use of opium at this stage of the disease explains this feature. The right testicle may be swollen and retracted, the course of the pain being towards this gland. The circumscribed swelling in the right iliac fossa when present is evidently of the utmost value in diagnosis. Its usual seat is below a line extending from the anterior superior spine of the ilium to the navel, nearer the former and two fingers' breadth above Poupart's ligament. It may lie nearer the median line or may approximate the iliac crest. Its exact seat may vary with the anatomical peculiarity of the appendix. The early products of peritonitis are obviously not to be recognized by physical signs. As the exudation increases dulness becomes apparent, but this sign may be obscured by intervening coils of intestine or the gaseous character of the contents of the abscess. A circumscribed resistance is felt on palpation though an anæsthetic may be required because of the tension of the abdominal muscles and the extreme sensitiveness. Rectal examination not infrequently permits the recognition of the tumor when abdominal palpation fails to disclose it. A sense of fluctuation is rarely perceived until later in the case; as a rule its appearance is so late as to be of little diagnostic value. Dr. Fitz does not believe that too great stress should be laid upon the diagnostic use of the aspirator. "If the aspirator fails to show the presence of pus even after repeated punctures in divers spots it by no means follows that pus is absent."

Errors in the diagnosis of appendicitis have been numerous, chiefly because the cardinal symptoms of localized pain, general heat, and circumscribed swelling have not been duly appreciated in their defined sequence. Of all the conditions with which perforating appendicitis may be confounded, stercoral cæcitis is perhaps the most common and the most important to distinguish. The history of this affection usually makes evident a period of protracted constipation in a person not especially young and vigorous and who may have had similar attacks. The pain is trifling for a long time and the sensitiveness slight. Fever is absent or of late occurrence. The tumor is present at the beginning as a distinct nodular or doughy mass, elongated and in the lumbar region. It is unnecessary to say that from a stercoral cæcitis may arise a perforative appendicitis.

The chief danger from the appendicular peritonitis is a tendency to become general. The beginning of general peritonitis occurred on the second, third, and fourth days in sixty per cent. of the cases as inferred from the nature of the pain, and in nearly ninety per cent. as suggested by tympanites.

Perforating inflammation of the appendix sometimes proves fatal from shock, though death usually follows the production of a general peritonitis from direct extension of the appendicular peritonitis or the rupture of adhesions. In the protracted cases death may result from exhaustion. Shock proves fatal within the first two days, death from an extended peritonitis within the first week and from a secondary general peritonitis as a rule during the first two weeks. The termination in resolution undoubtedly occurs, but no absolute evidence of the proportion of this class of cases is at present attainable. The possibility of a termination by resolution must be recognized and the earliest therapeutic efforts should have this result in view, especially as these efforts also tend towards localizing the peritonitis. But, as Pepper states, "the unjustifiable delay permitted in many cases of typhlitis, whilst hoping day after day for the more definite detection of suppuration, is the direct cause of many avoidable deaths."

To keep the bowels quiet should be the first and last thought and it should be obtained by absolute rest in bed, liquid diet, and above all, a sufficient quantity of opium to neutralize pain. A cathartic may be demanded by the patient and an enema be thought desirable as an aid to diagnosis, but it must be remembered that these may be the means of exciting a fatal general peritonitis. If after the first twenty-four hours the peritonitis is evidently spreading and the condition of the patient is grave the question should be entertained of an immediate operation for exposing the appendix and determining its condition with reference to its removal. If any good results are to arise from such treatment it must be applied early. Willard Parker considers an incision made between the fifth and twelfth day practicable, safe and justifiable, but it appears from Dr. Fitz's tables that thirty-four per cent. died during the first five days; it is thus evident that the date fixed by Dr. Parker is too late.

The conclusions to which the consideration of the subject leads the author are as follows: The vital importance of the early recognition of perforating appen-

dicitis is unmistakable. Its diagnosis, in most cases, is comparatively easy. Its eventual treatment by laparotomy is generally indispensable. Urgent symptoms demand immediate exposure of the perforated appendix, after recovery from the shock, and its treatment according to surgical principle. If delay seems warranted, the resulting abscess, as a rule intraperitoneal, should be incised as soon as it becomes evident. This is usually on the third day after the appearance of the first characteristic symptoms of the disease.

MEDICAL SECTS AND CLINICAL INSTRUCTION IN PUBLIC HOSPITALS.

Six or eight months ago petitions, upon which hearings were given, were presented to the trustees of the Boston City Hospital, asking that "homœopathic treatment may be furnished at the hospital for those who prefer it:" that, "all clinical advantages and privileges of the hospital be made equally available to all students pursuing the study of medicine in Boston;" that, "all medical students and physicians be allowed to visit the hospital for purposes of medical study and observation, on equal terms and subject to the same conditions."

The trustees, having during the intervening months, consulted with many gentlemen acquainted with hospital management, having examined the systems of hospital administration in other cities, having addressed inquiries to all the principal hospitals of the country as to their position and practice in these matters, and having received official answers from nearly one hundred hospitals, have at length, through their secretary, given an answer to the several petitions, after what must be admitted to be mature and careful consideration, involving much self-imposed labor.[1]

The introduction of homœopathic treatment for a portion of the patients would involve, it is stated, a change in the administration of the hospital which must be accomplished, if at all, in one of three ways: By introducing another and independent body of physicians and surgeons, side by side with the present staff; by setting apart separate existing wards with a separate staff; by building new wards for the homœopathic treatment.

Having kept constantly in view the cardinal principle, that the primary object of a public hospital should be the welfare of the sick; finding by their investigations that the introduction of medical sectarianism has only been attempted in two out of all the public hospitals communicated with, and not, as it would seem, successfully in either of those; believing that if one medical sect be provided for others should in justice be equally considered; encountering many practical difficulties, some of which are enumerated and others not, the trustees conclude that the desire of the homœopathic petitioners under the first petition can be fairly or satisfactorily gained only by new and separate buildings under a distinct management, and that the city government, not the trustees of the hospital, is the proper body to determine how and when the city shall provide treatment specially homœopathic, or specially anything, to such of its citizens as shall desire such special treatment when compelled to seek assistance at a public institution.

The question of instruction to students was considered:— 1st. As to surgical operations and clinical instruction in the amphitheatre or other public room; 2d. As to instruction in the wards or in the outpatient rooms; 3d. As to the admission of female students to the various privileges.

An instructive abstract is given of the practices prevailing upon these points at the leading hospitals of the great centres of medical education in this country, and, in addition, the answers from ninety-one hospitals are tabulated. In all the *public* hospitals, except two, the staff is composed of regular physicians, and of these two, one has both regular and homœopathic members, and the other has no visiting staff proper, but a head or superintendent (regular) assisted more or less by members of "all the schools, regular, irregular, and defective." Of all the hospitals answering the inquiries, five were homœopathic, the remainder were regular.

As a result of their consideration of the question of instruction to students — keeping always carefully in mind the welfare of the patients — the trustees have concluded to extend somewhat the previously existing regulations with reference to clinical instruction (medical and surgical) and surgical operations in the amphitheatre, and to contract somewhat the regulations with reference to clinical instruction, and visits by students in the wards of the hospital. In future, members of the surgical visiting staff may, on regularly appointed days, perform operations in the amphitheatre, and members of both medical and surgical visiting staff may likewise give instruction there in their respective departments. When the amphitheatre is so opened for operations and instruction, physicians having received a degree of doctor of medicine, and students, of one year's standing, of any duly incorporated college or school of medicine or surgery, may be admitted in such numbers and on such regulations as the trustees may from time to time determine. Whenever the operating surgeon or the physician shall deem a case improper for consideration, in the presence of students of both sexes, he may reserve such case for the close of his operation or lecture, and require the withdrawal of all male or female students, as the case may be. No female patient shall be taken into the amphitheatre without the attendance of a nurse (female), and no operation upon a female patient requiring the exposure of the genital organs shall be performed in the presence of male visiting students.

Female patients in the amphitheatre would seem, therefore, to enjoy a certain amount of protection not

[1] Action of the Trustees of the Boston City Hospital, upon the Petitions for the Introduction of Homœopathic Treatment, and for the Admission of Medical Students to Surgical Operations and Clinical Instruction.

accorded to male patients in so far as the clause concerning a class of operations requiring exposure is mandatory as regards them, but only permissive as regards the modesty of male patients.

In respect to ward visits it is determined that, physicians and medical students accompanying, on his invitation, a member of the staff in his hospital visit or examinations, shall be limited to such numbers, not exceeding twenty, and shall conform to such regulations as the trustees may from time determine, and shall further observe all such requests as to order and propriety as the attending physician or surgeon, or the Superintendent, may make. This change, we think, is likely in the long run to prove advantageous to students and certainly to some patients.

This report is an able, a careful and a laborious one. It reflects credit upon the faithfulness, the intelligence and good judgment of those who make it, and can hardly fail to give general satisfaction. It will doubtless prove a useful guide to others who may have to consider similar questions. The portion devoted to the practicability of introducing medical sects into public hospitals is in accordance with the views of the best authorities upon hospital administration.

THE SERPENT-MAN.

WE have been treated to such large doses of mental stimulants in the way of advertisements, especially by dime museums, that the announcement simply of "the earth's eighth wonder," the "serpent-man," etc., etc., would hardly whet the mental appetite to an extent the real worth of this meritorious phenomenon with the above fanciful designations would justify, even though his pictures, pasted on the bill-boards in our streets, in attitudes not at all "stained-glass," give evidence of something more unusual than the common run of contortionists.

A man that can wind himself up so that his head appears to be the radiating centre of arms and legs, in short, to be where the umbilicus ought to be, like the curious, carved monster on the celebrated Aztec stone, is sure to commend himself to the curious public, but the medical man can find an interest in the exhibition entirely apart from curiosity.

Herr or Signor Marinelli is a small man, of twenty-three years of age, with a good figure, who has devoted himself to increasing the flexibility of his back since he was nine years old, being led to it by a natural aptitude for tumbling, as exhibited among his comrades. An inspection of his figure shows an increase of the normal lumbar lordosis, and in place of the physiological curve between the shoulders, with the convexity backward, a complete dorsal lordosis is to be noticed, that is, the spinal column is slightly curved in. This is unaccompanied by the protuberant abdomen usually seen in lordosis, as the abdominal muscles are unusually strong, and hold back the intestines, which are probably not loaded with any superfluous fat in the mesentery and omentum. The ribs are prominent forward, as if the chest were large — an appearance due to a change in the thorax from the unusual shape of the thoracic spine. The pectoral muscles are not large, but the trapezius, the scapulæ, and the back muscles are well developed, and in excellent condition.

The mobility of the spinal column is increased in all its extent, but chiefly in the lower dorsal vertebræ; the backward motion of the spine is noticeably increased, but this contortionist illustrates remarkably well the physiological fact that the chief motion of the human spine is in the lower dorsal and cervical regions, and the increase in the flexibility of the spine is chiefly an unusual increase in the physiological mobility, and not a special anatomical freak.

It is, of course, impossible to determine how much of the present condition is a natural aptitude, and how much is acquired; but in the absence of any evidence of abnormality of structure, it is fair to infer that the natural flexibility in a nimble boy has been largely increased by painstaking and continued exercise. The curves in the back to be seen at present have been in all probability acquired. Instead of growing round-shouldered from his occupation, he has become the reverse, being probably the best living example of the kind of man "who stands up so straight that he leans over backwards," as well as an example for the encouragement of those who attempt to rectify spinal curvature by systematic exercises.

MEDICAL NOTES.

— The active principle of cod-liver oil, of which it forms one and a half to six per cent., is said to have been obtained by Mr. Lafarge, of Paris, and to have given excellent results when used in place of the crude oil. The substance is called morrhuol, and contains twelve times as much iodine, bromine, and phosphorus as the original oil, with none of the fat.

— An interesting contribution to the study of consanguinous marriages occurs in the paper of Dr. Baelz on the Japanese, referred to in another column. He says: "Near the bathing resort, Atami, there is situated a small island, named Hatsushima. The inhabitants of that island, nearly three hundred in number, have for more than two hundred years exclusively married amongst themselves; strange blood has never entered the island. Those people live by fishing, and from the proceeds of a small trade with the neighboring coast. They are physically and mentally quite normally developed, and their statistics show a larger number of births, and a smaller number of deaths in proportion than any other part of the Japanese empire."

NEW YORK.

— Health Commissioner Otterson, of Brooklyn, has submitted to Mayor Whitney a report in regard

to the disposal of the city's garbage, in which he favors the system of burning now in use in Toronto and other Canadian cities. Retorts for this purpose cost about $5,000 each, and Dr. Otterson thought that two would be sufficient for Brooklyn's wants in this respect.

— At a dime museum on the Bowery, the "Princess Lucy," nineteen years old, twenty-seven inches in height, and weighing twenty-three pounds, was recently married to "General Rheinbeck," who is twenty-one years of age, thirty-six inches in height, and weighs forty pounds. The fat woman of the museum acted as bridesmaid, and the fair bride is said to have blushed becomingly when the officiating clergyman, who was of Teutonic extraction, told her that she should bring up her children as "goot rebublican citizens of the United States." We extend our sympathies to the accoucheur!

— The annual meeting of the Board of Trustees of St. Luke's Hospital was held October 18th. The report of the Superintendent showed that the past year had been one of the most prosperous in the history of the institution. About $65,000 was received during the year from bequests and for endowments of free beds — an amount greatly in advance of the usual receipts of this character. The $100,000 left the hospital by the will of Wm. H. Vanderbilt is being used in part to erect a building for the Superintendent and other officers, and this, when completed, will leave a considerable portion of the hospital building hitherto occupied for this purpose vacant for patients. An upper story, which has not before been used, is also to be utilized during the coming year, so that the capacity of the hospital will be nearly doubled.

— A case of peculiar moral obliquity or ignorance in an individual having in charge the care and instruction of the young, has come to light in Westchester County, if the facts of the case are correctly reported. For a long time a very offensive odor, it seems, has been noticed at Lake Mohigan, and the attention of the Board of Health having at length been directed to the matter, an investigation showed that it was due to a sewer running directly from the Lake Mohigan Academy into the water of the lake. Not only has the principal of the academy permitted this disgraceful state of affairs to continue for an unknown period; but now that he has been requested by the sanitary authorities to remedy the evil, he flatly refuses to do this, and denying their authority to enforce an abatement of the nuisance, threatens a legal fight if they attempt it.

— At the last meeting of the New York Board of Education, the special committee on education presented a report recommending the tentative introduction of industrial education in the public schools. It stated that they believed manual training to be an important branch of education, and that it would be a great relief to the scholar, whose mind is burdened with ordinary lessons, enabling him to acquire such lessons with greater facility, on account of the variety thus afforded in his work. It would open new fields of employment to thousands of pupils, many of whom, in order to earn a living, are now compelled to leave school before completing the first grade of the grammar department. Technical education could be introduced either by establishing separate schools for manual training, or by teaching it in the present school buildings. The report went on to say:

"Your Committee are of the opinion that we should go to work tentatively. Any theoretical programme which might now be laid out would not do. Practical experience is needed. The Superintendent of School Buildings informs us that there are vacant rooms in various schools. In some or all of these we might teach mechanical or constructive drawing, modelling in clay, word-working by means of hand-tools, etc. If it should be found inexpedient to introduce power into any of our present buildings, some lofts might be rented for that purpose. In view of what we have stated, we unanimously recommend that $50,000 be asked from the Board of Estimate and Apportionment, in order to begin the experiment for the male grammar schools. The girls in our schools should also receive the benefit of a more practical education. Elementary cooking could be taught to a large number of the girls at a comparatively small expense. Your Committee are of opinion that twelve lessons, of two hours each, would suffice. We would also advocate that sewing be made compulsory in some classes of the grammar schools. At present it is made compulsory only in the primary department for one hour each week." The Committee also thought that some lectures on general housekeeping ought to be delivered to the girls in grammar schools, and recommended that an appropriation of $10,000 be asked for to introduce the subjects mentioned experimentally in the girls' schools.

Miscellany.

RESECTION OF LUNG AND REMOVAL OF A KIDNEY.

M. Demons read an interesting note at a recent meeting of the Paris Surgical Society.[1] An adult was stabbed between the ninth and tenth rib. A portion of the lung-tissue protruded, and formed a mass about as large as an apple; the same day the patient passed blood with his urine, indicating a wound of the kidney. M. Demons resected, by means of the écraseur the hernial portion of lung, and applied the thermocautery to the surface. Some days after the operation, there was purulent effusion on the left side of the thorax; chemical analysis of the fluid proved it to be principally urine. It was decided to remove the kidney. Nephrectomy was performed in the lumbar region; the twelfth rib made the operation more difficult; but M. Demons, remembering M. le Dentu's opinions, carefully avoided cutting it. The pedicle of the kidney was divided, and carefully ligated. The wound was sutured with metallic threads; reunion took place

[1] London Medical Record, August 16.

by first intention, but two months subsequently a mass of cellular tissue sloughed away and opened the cicatrix. It is now six months since the operation was performed, and recovery appears to be perfectly established.

THE PHYSIOLOGY OF THE EYE OBLIQUITY OF THE JAPANESE.

DR. E. BAELZ, in a communication to the German Anthropological Society, 1885, No. 10, gives some interesting contributions to the ethnography of the Japanese. From his paper, as published in the *Sei-I-Kwai*, we extract the following:

"The *eye* of East Asiatics, as is well known, is oblique, but this obliquity is exclusively based upon the position of the lids; the apple of the eye has nothing to do with it, and perhaps not the orbit. It is essentially caused by an arched fold descending from the upper lid over the inner angle of the eye, covering it, and extending inward and downward; and this fold, on account of its direction upwards and outwards, makes the eye appear more oblique than it really is. An exact measurement of the difference of height between the inner and outer angle of the eye shows that, in most cases, that difference is not considerable. The said fold is more or less present in the eyes of European children, so that one can get an idea of it by examining their eyes. It frequently extends over the whole length of the upper lid, so that it entirely covers the free edge of the lid, and with it the roots of the eye-lashes, which appear very short on that account. Since the inner angle of the eye is rounded off by the fold, and the outer angle is very sharp, the Japanese eye frequently very much resembles a button-hole. I believe it is caused through the skin, which, in the European, covers the upper part of the bridge of the nose; for the peculiarity disappears if the skin between the eyes of a Japanese is raised to the height of a European bridge of the nose, and in the case of a European, it can be produced by pushing the skin of the bridge of the nose towards the eye. There are, however, peoples with flat bridges of the nose without this fold.

"Of further importance as to the appearance of the Japanese eye, is the great distance between the eyebrow and the free edge of the eye lid, and the bolster-like appearance of the skin between them. In the Ayrian, almost without exception, there is an indentation under the eye-brow; in the Japanese, the upper lid, seen from the side, mostly is only the continuation of the skin of the forehead, interrupted by no indentation. The orbs project more than those of Europeans, and frequently so much, that seen from the side, they project further than the bridge of the nose."

SCARLATINA *SINE* EXANTHEMA.

A REVIEW of a carefully-prepared series of observations by Robert, in the *Revista de Ciencias Méd.*, which we find in the *Archives of Pediatrics* for August, shows that the author's experience in a number of carefully-observed cases revealed the following: The patients which were seen were all between the ages of two and nine years, suggesting the idea that the first and second infancy had something to do with this anomaly as to the exanthema. Fever was present, as in the ordinary form of the disease, but did not go beyond 39° C. Angina also was manifest in connection with a rapid and febrile pulse. The angina was of a catarrhal or hyperæmic type, however, and was not attended with enlarged tonsils, nor with pultaceous nor diphtheritic deposits. The tongue was red at the commencement of the disease, but there were no decided symptoms during the first few days of any grave internal disorder. The fever was of an intermittent character, of either the single or double quotidian variety. After these phenomena of the first stage of the disease have disappeared, a very important sign may be observed, namely, the presence of albumen in the urine. It may not be in large quantity at first, and may require the more delicate tests to discover it, such as picric acid, or the acid nitrate of mercury. Albuminous nephritis, whether medullary or cortical, with all its usual symptoms, constitutes the second stage of this disease, which is called the *white* form of the disease, as the skin is not colored red at any time during its progress — the renal lesion from the first appearance of albumen in the urine. This may happen within a few days of the first symptoms of the disease, or it may be deferred for a longer period, as in ordinary scarlatina. If the fever has remitted, it may appear, together with the other symptoms of acute parenchymatous nephritis, reaching 40° C., or even a higher point. The urine is usually scanty as to quantity, dense, contains blood, much albumen, many epithelial cells, and epithelial casts. The quantity of urea is diminished, ansarca is quite general, and the serous cavities, and especially the peritoneal, contain much fluid. In addition, there are visceral disorders which are common to uræmia, and which vary, as the lesions are in the nervous centres, the retina, the respiratory apparatus, the heart, or the gastro-intestinal tube. These symptoms, though serious, are not necessarily fatal, but the prognosis is less favorable when they occur in connection with a relapse which has made its appearance fifteen or twenty days after the appearance of the eruption. The treatment should consist of vapor baths, jaborandi, pilocarpin, and opium. The diet should be composed mainly of milk. Acetate of potash and quiniæ are useful for their diuretic and tonic effects.

THE POPE'S CHOLERA HOSPITAL IN ROME.

A CORRESPONDENT of one of the London papers gives an interesting account of the "model cholera hospital" which the Pope has caused to be erected in Rome for the accommodation of cholera patients in case of an epidemic. Contact with the outer world is carefully guarded against by grated windows, telephones, and by a revolving barrel with half its circumference open, by which provisions are taken into the hospital. The water-supply is drawn from a well, and is quite separate from the city supply. The drain is formed of an iron tube sixteen inches in diameter, the joints being hermetically sealed with lead. There is a disinfecting boiler in which corrosive sublimate is placed. There is a room called the "chamber of observation," which has a staircase leading up to the first floor. In this room dead bodies are placed for a given time, as it is well known that cholera patients

often show signs of being quite dead when really only apparently so. The room is, by means of an electric apparatus, in communication with the director's office. The body being laid on a bed, both hands are put into a sort of copper muff; between the hands is put an instrument so sensitive that, should there be the slightest movement of the hands or any other part of the body, this instrument would instantly close the electric circuit, and the bell in the director's office would be set ringing; at the same moment another instrument registers the number corresponding to the bed upon which the body is lying. The chamber is warmed by steam so as to facilitate resuscitation. The laboratory is provided with a gasometer for the storage of oxygen, which is taken to the wards for administration in gas bags. On the ground floor are four wards for doubtful cases; should they get worse they are sent up in the lift to the cholera wards above, their clothes and bed-linen being immediately burned. Another room is set apart for women in childbirth, and there are two more for undressing patients, so that the infected clothes may be destroyed, the Pope furnishing new clothing for all recovered cases. The cubic space allowed for each bed is thirty-six cubic metres. The ventilation is carried on by means of funnels with gas jets below. The chapel is in communication with the sacristy of St. Peter's, so as to form an easy access for the Pope should he wish to visit the hospital; but before returning into the sacristy his Holiness and suite would have to go into a room near it for disinfection. In the event of there being more cases than the hospital can hold, provision has been made for building large sheds in the garden. This hospital was begun in October, 1884, and finished in April, 1885. When the cholera was raging with such violence in Naples, Leo XIII determined upon making preparations should the scourge visit Rome. It has never been necessary to use it, but it is always ready in the event of an outbreak, and should prove of much use in extirpating it.

A BALD AND TOOTHLESS FUTURE.

Under the above somewhat startling caption a writer in the *Popular Science Monthly* gives some interesting facts gleaned by him while in the exercise of his duties as a reporter in some assemblies of Boston and other American cities. He says, under the subject of baldness, that in most of the Eastern cities, fully thirty per cent. of the men over thirty years of age show unmistakable signs of baldness, while nearly twenty per cent. have spots on their heads that are not only bald, but actually polished with the gloss that is supposed to belong to extreme old age alone. "I have been in the majority of the churches and theatres," he continues, "in all the large Eastern cities, as well as in Chicago, St. Louis, and other places of the West, and have verified my assertion by actual count. From my observation I find that bald-headed men are most plentiful in New York and Boston. After these come Philadelphia, Washington, and the Western towns. I say 'men,' for two reasons: (1) Because women usually wear their hats or bonnets on such occasions, thus covering their crowns. (2) In case their hats are removed, the hair is combed up so as to cover any possible bald spot, or else there is an artificial "switch" to hide the defects of nature. So, without indulging in any speculations regarding what may be, I will confine myself to what is to be seen.

"Here are a few observations taken in Boston. Trinity Church: 243 men; 71 actually bald, 46 indications of baldness. King's Chapel: 86 men; 38 actually bald, 14 indications of baldness. Hollis Street Theatre, orchestra at performance of the "Mikado": 63 men; 27 actually bald, 10 indications. Boston Theatre — Judic: 126 men; 51 actually bald, 43 indications.

"These observations were taken from the more cultivated classes of society, and do not give a fair representation of the Boston head, as repeated calls at the dime museums and cheaper variety performances demonstrated. For instance, of the 30 men seen in the seats of the World's Museum in Washington Street, but 8 were bald, while only 5 others had thin hair, showing that baldness was simply a question of a very few years. Again, of 40 men at Austin and Stone's Museum, 22 had their heads well covered; and at the Windsor Theatre (variety) I found less than twenty-five per cent. who had thin hair.

"On the other hand, at shows and entertainments of more refinement, the bald-headed element was considerably larger. Of two nights when Patti sang at the Boston Theatre there were forty-six per cent. of bald heads on one occasion and forty-two on the other. When De Lussan appeared in "Fra Diavolo" I discovered thirty-eight per cent. of baldness, and at one of Matthew Arnold's lectures there were forty-six per cent. In fact, out of hundreds of observations, extending over several years, I have found that the higher the price of admission, and presumably the more refining nature of the performance, the larger the per cent. of bald heads. One night I counted the occupants of a few settees in my immediate vicinity at an exhibition which John L. Sullivan gave at the Mechanic's Fair Building, and was surprised to find that less than twelve per cent. of the men were bald. As this was a show where the spectators had the privilege of retaining or discarding their hats at pleasure, I think it was not a fair test."

Correspondence.

TO ABORT A FELON.

Roxbury, Oct. 23, 1886.

Mr. Editor,— Some one asked how to abort a felon. I will tell him how I have aborted a great many, though of course this cannot be done except in the earliest stage. Tie a rag loosely around the finger and keep it constantly wet with cold water. It cures often; but probably some more fantastic appliance will better please most patients, and give them a higher opinion of the surgeon's skill.

Yours respectfully Edward T. Williams, M.D.

BOYLSTON PRIZE ESSAY.

Boston, Oct. 19, 1886.

Mr. Editor,— Would you kindly inform me through your columns if the subject for the next Boylston Essay has been announced yet, and if so, what the subject is, and greatly oblige A Reader.

["A reader" is referred to page 9 of advertisements in the issue of this *Journal* for Oct. 21st, the current year. — Ed.]

OBITUARY. J. C. HOADLEY, ESQ.

In the death of Mr. J. C. Hoadley the State has lost one of its best citizens. A man of sterling integrity, uncompromising honesty and unwavering patriotism, he combined the strictest sense of personal and public duty with a kindness of feeling and courtesy of manner that made him one of the finest types of New England character.

As a member of the State Board of Health of Massachusetts, the earliest in this country, the community, and especially the medical profession, has great cause of indebtedness to him for the ability, zeal, and wisdom with which he performed his duties as a member of that board. In the early struggles of the board, when its continued existence was doubtful, in the prolonged contests which closed nearly fifty slaughter-houses in Brighton and freed the State from the nuisances of noxious trades, during the years when the board was threatened on many sides and when its maintenance, through its delicate and difficult duties, was due only to the wisdom of its management, Mr. Hoadley's close devotion to his work, his patience and thoroughness in investigation, his quick conception of the truth, his unyielding adherence to the right, not listening for a moment to a time-serving policy or to the behest of politicians, his fairmindedness, good judgment and strict sense of justice, and withal his modesty, kindliness and consideration of the feelings of others, make him one in whom his associates could place the most absolute confidence, and upon whom they could depend in every emergency. They always felt that the final success of the board was largely due to him. He was a valued and devoted friend in whose friendship they rested, and in whose death they have suffered a deep personal loss. In his official work, as in his relations to his fellow citizen, and in his professional capacity as a civil engineer, he devoted a highly cultivated and scientific mind, with rare faithfulness, to the exact fulfilment of the least, as well as the great, duties which came before him.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 16, 1886, TO OCTOBER 22, 1886.

WISSEL, DANIEL, captain and assistant surgeon. Relieved from duty at Fort Fred Steele, Wyo., and ordered to proceed to and take station at Fort McKinney, Wyo., reporting to the commanding officer of that post for duty. S. O. 135, Department of Platte, October 15, 1886.

EDIE, GUY L., first lieutenant and assistant surgeon. Having returned from detached service in Department of Arizona, will join his station at Fort McIntosh, Texas. S. O. 144, Department of Texas, October, 13, 1886.

CHAPIN, ALONZO R., first lieutenant and assistant surgeon. Relieved from duty at Fort Laramie, Wyo., and ordered to Fort Washakis, Wyo. S. O. 137, Department of Platte, October 19, 1886.

IVES, FRANCIS J., first lieutenant and assistant surgeon. In obedience to instruction received from the Division Commander, ordered to report in person at headquarters, Department of the Platte, for duty. S. O. 146, Department of Texas, October 16, 1886.

KENDALL, WM. P., first lieutenant and assistant surgeon. Leave of absence extended fifteen days. S. O. 229, A. G. O. October 14, 1886.

BANISTER, W. B., first lieutenant and assistant surgeon. Assigned to duty at Fort Wingate, N. M. F. O. 97, Department of Arizona, September 29, 1886.

MASON, CHAS. F., first lieutenant and assistant surgeon. Relieved from temporary duty at Fort Verde, A. T., and ordered for duty at Fort Huashuca, A. T. S. O. 99, Department of Arizona, October 12, 1886.

BOSTON CITY HOSPITAL.

EXAMINATION OF CANDIDATES FOR HOUSE OFFICERS.

The semi-annual competitive examination of candidates for appointment to the positions of House-Officers at the Boston City Hospital, for the term of service beginning on the first Monday of January next, will be held at the Hospital at three o'clock, P.M., on Thursday, November 11, 1886. See advertisement, p. 2.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Society will be held at the Medical Library, 19 Boylston Place, Monday evening, November 1st, 1886, at eight o'clock. Readers: Dr. George W. Gay, "A Case of Laparotomy for Acute Peritoneal Adhesions: Recovery." Dr. J. H. McCollom, "Injuries of the Shoulder."

37 Charles St. CHARLES P. STRONG, M.D., *Secretary*.

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION. — The first meeting of the season will be held at 17 Boylston Place, on Wednesday evening, November 3d, at eight o'clock. Communications: Dr. Maurice H. Richardson, "A Case of Gastrotomy for the Removal of a Plate of Teeth lodged in the Œsophagus behind the Heart: Recovery." Dr. Royal Whitman, "A Report of Four Cases of Excision of the Hip performed in 1882."

SAMUEL J. MIXTER, M.D., *Secretary*.

180 Marlborough St.

SUFFOLK DISTRICT MEDICAL SOCIETY. — There will be a stated meeting on Saturday, October 30, 1886, at eight o'clock, P.M., at 19 Boylston Place. Dr G. H. Monks, "A Case of unusual Deformity of both Hip Joints: Exhibition of Patient." Dr. O. K. Newell, "The Male Urethra, some Observations on the Anatomy of, in Relation to Endoscopy, Litholapaxy, and Catheterization." Incidental Business: Action on a proposed Amendment to By-Law XV, by the addition of the following clause: "In making nominations for the officers of the Society in 1887 and each subsequent year until otherwise ordered, the Nominating Committee shall not nominate any member who has held any office in this Society for two consecutive years immediately preceding the year for which such nomination is made. Nominations for Treasurer, Secretary and Librarian are excepted from this restriction."

Choice of a committee of five to prepare a list of candidates for officers of the Society. Supper after the meeting. Members are requested to notify the Secretary of any change of address.

200 Dartmouth St. HERBERT L. BURRELL, *Secretary*.

DEATH.

Died in Cambridge, Mass., October 18, 1886, Alley Talbot Wakefield, M.D., M.M.S.S., aged thirty-one years.

BOOKS AND PAMPHLETS RECEIVED.

Diphtheria and its Treatment, an Essay. By J. Pirnat, of Evansville, Ind. 1886.

Report of Two Successful Cases of Trephining for Traumatic Epilepsy. Carlos F. MacDonald, M.D. (Reprint.)

The Human Color-Sense Considered as the Organic Response to Natural Stimuli. By L. Webster Fox, M.D., Philadelphia, and George M. Gould, A.B. 1886. (Reprint.)

Is Electrolysis a Failure in the Treatment of Urethral Strictures. By Robert Newman, M.D., New York. New York: 1886. (Reprint.)

Transactions of the Medical Association of the State of Missouri at its Twenty-Ninth Annual Session. Held at St. Louis, Mo., May 3, 1886.

Therapeutische Notizen aus Dr. Letzel's Policlinic für Haut Krankheiten und Syphilis in München. III. Das Oleum Santalum ostindic. Als Anti-Blennorrhagicum.

Varnier, Interne des Hôpitaux de Paris, sous la Direction de M. le Docteur Pinard, Professeur Agrégé à la Faculté de Paris, Accoucheur de l'Hôspital Lariboisère. Paris. 1886.

Outlines of the Pathology and Treatment of Syphilis and Allied Venereal Diseases. By Hermann von Zeissl, M.D., Late Professor at the Imperial-Royal University of Vienna. Second Edition, Revised by Maximilian von Zeisel, M.D., authorized edition translated, with notes by H. Raphael, M.D., Attending Physician for Diseases of the Genito-Urinary Organs and Syphilis, Bellevue Hospital, Out-Patient Department, etc. New York: D. Appleton & Co. 1886.

Forty-Fourth Report to the Legislature of Massachusetts Relating to the Registry and Return of Births, Marriages and Deaths in the Commonwealth for the Year ending December 31, 1885. Together with the Report Relating to the Returns of Libels for Divorce and to the Returns of Deaths investigated by the Medical Examiners for the Year 1885. Prepared by the Secretary of the Commonwealth, with Editorial Remarks by Frank Wells, M.D. Boston: State Printers. 1886.

Lecture.

ON TETANY AND TETANILLA.[1]

BY JULIUS ALTHAUS, M.D., M.R.C.P. (LOND.),
Corresponding Member of the New York Academy of Medicine, Senior Physician to the Hospital for Epilepsy and Paralysis, Regent's Park, London.

ANOTHER important feature of tetany upon which I must dwell now, is an alteration in the electrical and mechanical excitability of the affected nerves and muscles, which occurs habitually in the cases now under consideration. Indeed, the faradic and galvanic excitability of the affected nerves, which was first examined by Benedict, and afterwards by Chvostek, Erb and others, is generally found to be much increased. A feeble constant current causes with the cathode not only the ordinary closing contraction much more readily than in the average healthy subject, but also tetanus of the muscles, which continues for some time; and what is rare in man, although not uncommon in the experimentalized frog, tetanus with opening at anode; and likewise with opening at the cathode. Ready responses are also elicited with a very gentle faradic current; and this ensemble of phenomena constitutes the reaction of convulsibility.

These signs are chiefly marked when the disease is at its acme, become less striking as the patient improves, and disappears altogether when he is well. They occur, however, only in the nerves and muscles which are actually suffering from tetany, not in all the muscles of the body; and this easily explains the apparent discrepancy in the results obtained by the different observers. Erb saw no reaction of convulsibility in the portio dura, while Chvostek found it very marked there in a case in which the muscles of the face were suffering from tetany. The electric tests are not only of diagnostic, but also of prognostic importance, as they sometimes persist when the patient is apparently quite well in other respects. They then show us that the disease, although in abeyance, is not actually conquered, and that there is a liability to a fresh outbreak of the other symptoms. When on the contrary, these tests have become normal, we may consider with certainty that the patient has recovered. They are, therefore, even a finer test than Trousseau's symptom, which may have disappeared at a time when the electricial reactions are still abnormal.

The mechanical excitability of the nerves and muscles is likewise habitually increased. A tap with the fingers or the percussion hammer on the nerves causes a sudden contraction in the muscles supplied by the same. This is more particularly noticeable in the sphere of the portio dura, where a slight blow in the region of the stylomastoid foramen, or the pes anserinus, or even the smaller branches of the nerve, effects sudden contractions of the facial muscles; and that not only during the attack, but also in the free intervals. A good way of producing the phenomena in question is that recommended by Schultze, namely, to pass the fingernail rapidly down one side of the face, from the temple to the cheek and jaw, when all the facial muscles are seen to contract. The reflex excitability of the skin is not exalted, and has indeed nothing to do with the appearances observed; for when the skin is taken up in a fold, and then strongly squeezed or pinched, no effect takes place. This increased mechanical excitability occurs in the portio dura habitually, even where that nerve has otherwise apparently escaped the influence of tetany; and it is therefore a very important diagnostic help. We must, however, remember that it is not invariably present. Moreover I have seen it in fresh cases of paralysis of the portio dura, concurrently with the increased voltaic excitability of the muscles; and also in some patients suffering from neurasthenia and hysteria. This shows that it will not do, in this as in other diseases, to rely on a single symptom for our diagnosis, but that we have to judge from the entire evidence which the aspect of the case offers to us.

Another symptom which exists during the free intervals, is a decided loss of coarse muscular power. This can be shown with the dynamometer, which I have found to register habitually 30° or 40° less than we should expect from the general build of the patient; and this loss is made up when they recover. There is also subjectively a feeling of lassitude, and fatigue is easily induced by slight muscular exertion.

While, therefore, tetany shows us a great variety of symptoms in the motor sphere, these are much less conspicuous in that of sensibility. I have already mentioned that much pain is sometimes experienced during the attack, more especially by sensitive children, who are at the same time reduced in their general health; but some patients say that the pain is insignificant. There is, however, generally tenderness to pressure and percussion over the affected nerves and muscles, more especially during the attack; and the same is found in the spine, particularly at that decisive point, the seventh cervical vertebra. Feelings of cold or heat, pins and needles, and other forms of paræsthesia, are occasionally present, but as frequently absent. Sometimes, however, the sense of touch is blunt, so that the patient feels objects as if padded, and imagines that he is walking on a carpet when on a bare floor. The muscular sense is habitually not impaired.

There are few other symptoms to mention. Sometimes there is redness and œdematous swelling, more especially in the smaller joints of the fingers and toes, but also in the wrist and about the ankle, leading us to suspect an attack of acute rheumatism or rheumatic fever. The temperature is mostly normal, but rises to 100° or 101° and even more in very severe or acute cases; and the pulse is thus accelerated, although habitually normal. There may also be headace, dizziness, flushing of the face, buzzing in the ears, impaired sight with large and sluggish pupils, rapid breathing, loss of appetite, obstinate constipation, and either unnatural dryness of skin or excessive perspiration.

In the majority of cases, however, the secretions do not appear to undergo any morbid change. It is true that Delpech has described albuminuric tetany; but these cases belong to a different class from those which we are now considering.

The duration of the individual attack of rigidity varies from a few minutes to half an hour and more; and the number of attacks during the day is even more variable. Sometimes there are only two or three, at other times there is an almost constant succession of them, reminding one of the status epilepticus, and going on night as well as day. The entire duration of the disease is rarely less than a month, and more commonly two or three months.

A few cases of tetany have ended fatally; but in

[1] Concluded from page 393.

spite of this, morbid anatomy has not furnished us with any precise data concerning the nature of any pathological change. One of Trousseau's patients died eventually of phthisis, and the upper portion of the cord appeared to be somewhat softened.

Kussmaul discovered myelitis in a young man who had been seized with paraplegia some weeks after having recovered from tetany; but the occurrence of paraplegia shows that the case was a complex one, and it therefore proves nothing. Langhans has microscopically examined the cord of a child which had died of tetany; he found the nerve-cells and fibres, as well as the interstitial connective tissue unchanged, but the arterioles showed thickening of the adventitia by deposition of cells, granules and pigment; and this was, in accordance with the symptoms observed during life, more marked in the upper than in the lower region of the cord, and more particularly about the anterior commissure. Such changes, however, which must have had a very slow origin, cannot account for a complaint which often originates suddenly, and ceases almost as quickly. I fear that just as little can be learned from a case of Weiss' where death took place from œdema of the lungs, following lobular pneumonia at the left base, and in which Zemann found the brain and membranes slightly œdematous, but otherwise normal; the capillaries of the gray centre of the cord appeared distended, and in parts there were very small capillary hæmorrhages, while the coats of the bloodvessels appeared normal. Such changes are probably rather effect than cause. In other instances hyperæmia of the dura mater, of the pia on the base of the brain, of the pons, bulb and upper portion of the spinal cord, and of the peripheral nerves which had more especially suffered during life, have been found; and must likewise be looked upon as secondary consequence rather than primary cause. Indeed, the great diversity and variety of these changes is in itself a proof that we have not as yet discovered the lesion of tetany; while other considerations lead us to think that, if there is a lesion, it is likely to be molecular rather than coarse, and that tetany belongs indeed to that large class of functional nervous affections which still awaits the application of finer tests than we command at present, before we can have a clear insight into their nature.

Nevertheless, some speculation seems to be allowed and even called for, more especially with regard to the localization of the trouble which is present in these cases. That it must be seated in some portion of the motor sphere, is quite evident from the symptoms we have to deal with, in which the affection of motility overshadows everything else. We have a large choice from the central convolutions of Rolando at one end of the tract, to the striped muscular fibres at the other. Which is primarily affected? DeLa Berge has pronounced himself for the muscular substance itself; Delpech, Hasse and others for the peripheral nerves; Kussmaul, Erb, and Berger for the spinal cord; Weiss for the sympathetic nerve, which he believes to be in a state of irritation or disturbance which is constant, but periodically increased, and while causing irritation of the gray matter of the cord and medulla oblongata, is itself caused by irritation in the bowel, womb, thyroid body, and other viscera. No one seems to have suspected the pons, crura cerebri, the central ganglia, the white internal capsule, and the central convolutions; and this appears quite intelligible if we consider that the symptoms are habitually symmetrical, while the usual affections of the parts just named are, on the contrary, unilateral. A great medical philosopher, Hughlings Jackson, considers tetany to be due to perverted cerebellar influence. He looks upon the brain as the centre for the ordinary voluntary movements of the limbs, and the cerebellum as the centre for continuous or automatic movements in the body. Now supposing the cerebral influence to be temporarily removed, the cerebellar influence would be unimpeded, and lead to rigidity of those muscles which during health are chiefly innervated by the cerebrum. I confess that this theory seems to me very far-fetched. Most physiologists consider not the cerebellum, but the medulla oblongata and the pons varolii to be the centres for automatic movements, while the cerebellum is credited chiefly with being the centre for the equilibration of the body. This latter function is, however, in no way disturbed in tetany, and this appears to me a sufficient reason for rejecting Jackson's hypothesis. It appears to me that some light may be gained by comparing tetany with another disease, in which we have likewise hardly any symptoms excepting in the muscles, and of which we know by dissection the true morbid anatomy. This is infantile paralysis, as caused by poliomyelitis of the anterior gray matter of the cord. In such cases we have not infrequently symmetrical paralysis of certain groups of muscles, just as in tetany we have the opposite condition, namely, rigidity which is most frequently symmetrical, and which affects with preference certain groups of muscles, leaving others intact. In infantile paralysis, which is a structural disease, we have chiefly paralysis of extensors and abductors, while in tetany, which I believe to be a functional disease, we have rather affection of the flexors and adductors. The nutritive centres of these groups of muscles we know to be the giant cells in the anterior cornua of the cord; and it is to an undue and exalted state of excitability of these cells that it seems to me most reasonable to refer the symptoms of tetany, just as we refer to destruction of these cells the opposite symptoms of paralysis in the groups of muscles for which we know them to be the centres. The localization of the trouble in the gray cells of the anterior cornua would then have to be sought in the lumbar, dorsal, or cervical region of the cord, or in the motor nuclei of the medulla oblongata, in accordance with the localization of the symptoms in the muscles of the lower extremities, the body, the upper extremities, the neck, head, face, eyes, pharynx and larynx. I confess that this seems to me the most natural explanation of the symptoms of tetany as they are seen clinically. Why irritation should in these cases affect more particularly the anterior gray cells of the cord and bulb, is, of course, quite as inexplicable as why it should affect certain gray centres in the brain in cases of epilepsy; but all these final reasons escape for the present our grasp, altogether, and we shall have to wait for a future period when in the natural course of evolution men's brains will have become much heavier and more finely organized than they are at the present day.

The diagnosis of tetany is not always easy, except in very pronounced or typical cases. Buzzard, a careful observer, has recorded a case as one of tetany, which was evidently, from his own description, one of hysterical contracture. The patient was a Jewish

girl, aged ten, who had suffered for three weeks from tonic, persistent contraction of the flexor muscles of the upper and lower extremity; there was some œdematous swelling, and over the knuckles a slight flush of redness, which made the case look like one of acute rheumatism. No intermission of symptoms was observed, nor did the muscles become relaxed during sleep. In a day or two, however, she began to improve, and had no return of the spasm. The chief feature of tetany, therefore, namely, the intermittent or paroxysmal nature of the muscular spasm, was absent, and the case can, therefore, not be said to be one of tetany. We have, indeed, in the diagnosis of this disease, to rely chiefly upon the paroxysmal occurrence of the spasms, the peculiarity that they spread in a direction from the periphery to the centre, on Trousseau's symptom of potentiality of spasm, which is elicited by compression, and on the electrical and mechanical convulsibility of the nerves and the muscles.

It is not likely that tetany should ever be confounded with epilepsy, as there is never any loss of consciousness in the former, and the whole group of symptoms of the epileptic fit is totally different from that of tetany. In Jacksonian epilepsy the symptoms are likewise widely different, and I should not refer to it if I had not known of a case in which this mistake was made by a practitioner. I will, therefore, say that in Jacksonian epilepsy there are tonic or clonic spasms, which generally affect not symmetrical parts, but one upper or one lower extremity; that they begin most frequently in the fingers, and travel from there upwards to the face, and sometimes end in general convulsions; that after the fit there is paresis in those parts which have been convulsed, and that this paresis eventually merges into paralysis; that, where general convulsions occur, consciousness is lost; and that after the parts have become paralyzed, they are still liable to be convulsed. In addition to these symptoms, we generally find also headache, optic neuritis, and vomiting, pointing to the formation of a tumor in the brain, or some allied structural disease of that organ.

Spinal meningitis has also been occasionally mistaken for tetany, yet the difference between the two conditions is likewise very striking. In meningitis we have fever, severe pains in the back; no such periodical remissions of the muscular spasms as in tetany; no Trousseau's symptom, and no increased excitability of the nerves to electrical and mechanical tests; and frequently, headache, vomiting, and a small and often slow pulse. Some forms of *acute rheumatism* have been confounded with tetany, but attention to the points which I have repeatedly named as characteristic for tetany will settle the question. In some forms of *ergotism*, spasms have been observed which resemble those of tetany, but ergotism is habitually endemic; it is generally connected with symptoms of spinal degeneration, such as loss of knee-jerk, lightning pains, impaired coördination, and not unfrequently, with epileptiform convulsions. Localized convulsions, such as histrionic spasm, torticollis, and convulsions in some individual muscles of the extremities, have also been occasionally described as tetany, but only from ignorance. Lastly, *tetanus* affects more especially the muscles of the jaw, tongue, pharynx, larynx, the neck, body, and the abdomen; reflex excitability is increased throughout the system; when the extremities are affected, it is chiefly the extensors; and the fingers and hands, which suffer more particularly in tetany, are spared in tetanus.

This seems to be the most fitting opportunity to speak of tetanilla, or Friedreich's paramyoclonus multiplex, as another form of muscular spasm which is not very uncommon in practice. I have seen the complaint, especially in neurotic subjects, frequently with a history of masturbation and inherited nervous affections, and between the ages of fourteen and fifty-four. All the patients were males, and no particular exciting cause could be discovered. It differs from tetany chiefly by the convulsions being clonic, and by the absence of prolonged muscular rigidity, and of Trousseau's symptom. The convulsions are, moreover, generally symmetrical; they cease during sleep, and do not impair motor power or coördination. The nutrition and electrical reactions of the muscles are normal, but their reflex excitability is increased, the knee-jerk, more especially, being greatly exaggerated.

The degree of spasm varies considerably, being in some cases slight, and in others of considerable severity; in some temporary, and in others almost incessant. All the muscles of the body may be affected, either simultaneously or successively. The spasm very commonly affects the adductor of the thumb, and the interosseous of the first finger, so that a movement as that of holding the pen for writing is produced, and the bellies of these two muscles are distinctly seen to contract under the skin. Each contraction lasts five or six seconds, is entirely painless, and is presently succeeded by a variable number of other contractions, of which, however, there are rarely more than six or seven. After this there is an interval of rest, and then a further similar set of contractions. Other muscles which suffer frequently are the deltoid, the rectus femoris, the flexor muscles of the legs, the orbicularis of the lips and eyes. Of the latter muscles, generally, only small portions are affected; for instance, the parts immediately adjoining the commissure of the lips, which are spasmodically contracted for a few seconds, then relax, and repeat this performance five or six times consecutively, after which the muscle is quiet for a few minutes, and then begins to play again.

In other cases the spasm is much more violent, and spreads over a much larger number of muscles. There may be a more or less constant clonic convulsion in the muscles of the face, neck, chest, and abdomen, as well as of the limbs, and which is occasionally intensified by more powerful contractions of individual muscles, by which the head may be suddenly pulled to the side or backwards, the eyelids closed, a sudden inspiration, like singultus, may be caused, and arms and legs thrown about. Perfect rest generally eases the spasms, while walking, using the hands, etc., is apt to increase them, and the patient may, therefore, be more or less disabled from following his occupation.

In one of my cases, that of a cabinet-maker, aged twenty-six, the right upper extremity was the exclusive seat of these clonic convulsions, which were quite sufficiently strong to throw the limb about in all directions, generally lasted two or three minutes at a time, were succeeded by four or five minutes' rest, and then began again. This man was utterly unable to earn his living through this most annoying affection. But it is chiefly the influence which the recurrence of such symptoms has on the mind of the sufferer that is of importance. One of my patients who suffered in this way had been told that it was a sign of beginning

progressive muscular atrophy, and as he had suffered from syphilis, and was in a low state of health, this prediction made him quite hypochondriacal. Another patient, a medical man, who had read about Jacksonian epilepsy without having ever seen a case of it, believed that these clonic spasms were the first symptoms of tumor of the brain, and that he was on the high road to become blind, epileptic, and imbecile. A third patient, likewise a medical man, had given up a large practice on this account, and gone abroad, being convinced that he was suffering from brain disease.

It is, therefore, important to know the differences which exist between the muscular twitches seen in progressive muscular atrophy, the spasms observed in Jacksonian epilepsy, and the clonic spasms of tetanilla or paramyoclonus multiplex.

The twitches or fibrillary motions of muscular fibres which are seen in patients suffering from progressive muscular atrophy are generally of a sluggish and worm-like description. There is nothing sudden or actually spasmodic about them, and as they affect more or less individual fibres only, they are not in general sufficiently powerful to cause movements of the limbs or any parts of them. They come and go, are easily excited by passing the finger-nail over the affected limb, or by exposure to cold, and are essentially diffuse in character. They must be considered as a sign that degeneration has been set up in the muscular fibres, and have, in general, a bad prognostic significance, showing that the disease is progressing. I need not further dilate upon the complete difference which exists between them, Jacksonian epilepsy, and tetanilla. The spasms of the latter are certainly not forerunners of any serious cerebral or spinal disease, for in one case which I have seen, they first occurred at sixteen years of age, and subsequently at various times; at fifty-four years, however, the patient was still in good health, although occasionally subject to attacks of this kind, which sometimes lasted for a few weeks, and then ceased. All my other cases have recovered. These spasms I believe to be owing to a similar, although much slighter degree of irritation in the giant cells of the anterior gray matter of the cord than those of tetany.

The *prognosis* of tetany is generally not serious, except in very young children, who have no power of resistance, and where spasm of the glottis, or general convulsions are often so easily induced.

It is also not favorable in persons who are extremely cachectic and reduced in strength. In most cases, however, tetany is not a dangerous complaint, and the patients recover in two or three months, more especially if placed in favorable circumstances.

For the *treatment* of tetany, Trousseau recommended bleeding and cupping of the spine; yet he mentions a case in which, by bleeding, the affection was made much worse and more general. At first the patient only suffered in his hands, so that the fingers were clenched and useless; but after the bleeding, the other parts of the limbs, as well as the muscles of the body, became affected, so that he sat quite motionless, and could hardly speak or breathe. In the present day bleeding is not likely to be resorted to, more especially as these patients are habitually in a state of exhaustion through persistent diarrhœa, or when convalescent from acute diseases. Just on the contrary, it should be our endeavor to build up the constitution of the patient, by removing him, if possible, from his habitual injurious surroundings, by giving him nutritious and easily-digested food, and such remedies as cod-liver oil, phosphorus, and arsenic. In recent cases, where exposure to cold and wet appears to have been the cause, the Turkish bath, or a wet pack, ammonia, and opium should be used. Where diarrhœa is present, astringents, more especially opium and aromatic sulphuric acid, are to be given. Where worms are suspected, the usual anthelminthic remedies find their appropriate sphere of action.

As direct sedatives, hydrate of chloral and urethan act better than hypodermic injections of morphia. Those highly popular remedies, iodide and bromide of potassium, have also been called in to our aid, and have proved useful in some cases. Electricity has frequently been employed without success, when applied to the affected nerves and muscles, while the application of a large anode to the spine, with the cathode at a distance, seems to be much more useful, as having a sedative effect on the unduly excitable gray cells. For cutting short an individual attack of tetany, which threatens life through involving the larynx and diaphragm, I know nothing equal to a subcutaneous injection of pilocarpine, which seems to act like magic. As soon as profuse perspiration is established, the spasm ceases, and the patient is rendered comfortable.

The treatment of tetanilla should be chiefly mental. The patient must be assured that there is nothing serious the matter with him, and that his brain is unaffected. Electricity used in the way just described, and Paquelin's cautery are other appropriate remedies, and rarely fail to cure an affection, which, while it is apparently insignificant, yet suffices to make life utterly wretched for these patients, and has driven some of them close to committing suicide. Indeed, there is nothing really insignificant in the practice of our profession, as slight causes may lead to grave results, often through the agency of the imagination.

ON THE EXACT MEASUREMENT OF THE ELECTRIC-CURRENT AND OTHER PRACTICAL POINTS IN THE DESTRUCTION OF HAIR BY ELECTROLYSIS, WITH ESPECIAL REFERENCE TO THE USE OF THE ABSOLUTE GALVANOMETER.

BY MORTON PRINCE, M.D.,
Physician for Nervous Diseases to Out-Patients, Boston City Hospital.

To remove hair by electrolysis is a very easy operation, but it is not so easy to do it without leaving behind disfigurements, either temporary or permanent. One of the disadvantages connected with the process is the dermatitis which is apt to follow the operation, to say nothing of the more severe papular inflammations, and not infrequent ulceration of the hair-follicles. Worse still, because permanent, are the scars. The latter, to be sure, even on a woman's face, are a small disfigurement, excepting when the process has been badly done, compared to that caused by unsightly hairs; still, they are scars. The dermatitis, to be sure, is only temporary, lasting only a few days, but while it lasts the skin is sore, and the face decidedly disfigured. The small ulcerations of the hair-follicles, small as they are, are of more importance, as they

lead to comparatively large scars, instead of the almost invisible cicatrices left, if any at all develop, by the process when properly done. It should be stated, however, that even minute cicatrices are not a necessary result.

It is generally stated by those having experience with the operation, that these ill effects are dependent upon the peculiarities of the individual skin, some skins bearing the operation without any bad after-effects, while others are easily inflamed. While there is considerable truth in this, and there is even a difference in the capacity of different parts of the skin of the same face to bear electrical currents without inflammatory reaction, still I have long suspected that the greater part of the difficulty is due to the intentional or unintentional use of excessively strong currents, and that such unintentional use is due partly to the fact that no proper means are employed to measure the strength of the current, and partly to the fact that a current from a given number of cells varies immensely in strength during the course of a single sitting, owing to the varying resistance offered by the skin. To overcome the undesirable effects which are consequences of these difficulties, I have hitherto advocated using the weakest currents possible, preferring to have more hairs come back to be operated upon again, rather than run the risks of pustules and disfiguring scars. Though secondary inflammation and cicatrices have in this way been mostly avoided, still the operation has been beset with great annoyances, such as the sudden weakening of the current below the strength practically necessary for the destruction of the hair papilla, with consequent imperfect results, necessitating tedious fussing with the battery, while again, the strength of the current may suddenly rise, for various reasons, above the required point, etc., etc. It was not till I began using the *absolute* galvanometer that I found a practical method of gauging the strength of the current, nor till then did I appreciate the extent of the fluctuations that may occur in the current strength in the course of a single sitting. Nothing is more uncertain and useless than the methods usually recommended by those who practise the operation for determining the strength of the current. Every writer on the operation, that I have seen, directs either that so many cells be used, or that a current sufficient to produce effervescence at the needle be employed.

Now, for reasons that will be presently explained, a most powerful current — one sufficient to produce severe destruction of tissue — may be unwittingly used without effervescence occurring, and in the second place, with the same number of cells, the current may vary five-fold, at least. It has been long known to electro-therapeutists that the number of cells, even aside from the difference in strength of the cells of different forms of batteries, is no guide whatever to the strength of the current. Another factor, besides the electro-motive force of the cells, must be taken into consideration, namely, the resistance to be overcome. This varies immensely, according to the size and construction of the electrodes, the degree of pressure with which they are applied to the body, the condition of the skin, its dryness or moistness, the portion of the body to which the electrode is applied, etc., etc. That these are no theoretical difficulties, but practical ones, may be seen by the results obtained in the following experiment: A current from the same number of cells was applied through the same electrodes, thoroughly wet at each application. The resistance of the skin over the spine had previously been reduced to a minimum by prolonged applications.

1. One electrode over palm, other over back of hand.	Current =	2	Milliampères.
2. One over spine, other over palm.	"	2	"
3. One over spine, other over back of hand.	"	6	"
4. One over each lateral half of back.	"	8	"
5. One over spine, other over forearm (front)	"	9	"
6. One over front, other over back of forearm	"	9	"
7. One over spine, other over back of forearm	"	10	"
8. Both ever spine.	"	10	"
9. One behind each trochanter.	"	11	"

Or, in other words, with the same given number of cells and the same electrodes, the current may be increased from two to five times, according to the different location of the electrodes in the same individual.

Again, with the positive electrode over the back or front of the forearm, negative on some part of the face, the current frequently varies, in the experience of the writer, between one and three milliampères, though the same number of cells be used, according as the needle is inserted in different parts of the same face.

The same thing happens, as would naturally be expected, with a current from the same number of cells applied to different persons, though the conditions be made as far as possible alike. I have found that after taking all possible precautions to apply the poles to the same regions, and after reducing the resistance of the skin to the minimum, that from twice to three times as strong a current may pass through one person as through another, though the same number of cells be used. Again, the fluctuations in the current strength dependent upon the size of electrodes may be seen from the following experiment:

The same number of cells were used in each case, and the electrodes applied to the same region of the body, namely, the thighs. The electrodes were of five sizes, No. 1 being the smallest, and about the size of the top of a slate pencil. The largest, No. 5, measured 3×6 inches, but the whole surface was not in complete contrast.

With electrodes	No. 2 and	No. 1, current	=	3	Milliampères.
"	No. 2 "	No. 3, "	=	6	"
"	No. 2 "	No. 4, "	=	7	"
"	No. 2 "	No. 5, "	=	9	"
"	No. 5 "	No. 5, "	=	14	"
"	No. 5 "	No. 1, "	=	6	"

To show how useless is effervescence as a guide, the following experience (of frequent occurrence) jotted down at the time, will show. The writer was removing from the neck some fine hairs, which grew at a very acute angle with the skin, and, therefore, somewhat difficult to destroy. After applying the current for the usual length of time, the hairs were found to be still firmly attached and no effervescence had occurred. The natural impulse would have been to increase the current, but a glance at the galvanometer showed that a current of three milliampères was passing — three times as strong as was necessary. The fault lay in an inaccurate direction given to the needle, and the inability of the gases to escape to cause effervescence.

Furthermore, effervescence is not necessary for the destruction of the hair bulb. Hairs can be destroyed, as I have repeatedly demonstrated, without the slightest appearance of effervescence.

The variations in the current-strength caused, even, by different modes of applying the electrodes to the skin may be seen from the following:

Twelve cells were used. A large electrode, $3\frac{1}{4} \times 6\frac{1}{4}$ inches, was applied to the forearm, while a small electrode, $1\frac{1}{2}$ inches in diameter was successively applied, first, to the centre of palm of hand so that only one surface was in contact with skin; second, between the thumb and palm so as to be held by pressure of the thumb; and third, to the centre of palm but grasped by the fingers. In this way the amount of surface in contact was successively increased. The strength of current obtained was as follows:

1st Method	$\frac{1}{4}$ Milliamp.
2d "	$\frac{3}{4}$ "
3d "	1 "

The following experiment was undertaken to show the variations in current-strength due to variations in size of the positive electrode in conjunction with a needle inserted into a hair follicle for electrolytic purposes.

1. Small electrode. ($1\frac{1}{2}$ inch) to palm	$\frac{1}{4}$ Milliamp.
2. " " " grasped	$\frac{3}{4}$ "
3. " " " to forearm	$1\frac{1}{4}$ "
4. Large electrodes, ($3\frac{1}{4} \times 6\frac{1}{4}$ in.) to palm	$1\frac{1}{2}$ "
5. " " " " to forearm	2 "

In other words, the large electrode applied to palm gave six times as strong a current as the small electrode, etc.

One more experiment shows the different results obtained by electrodes of different sizes, construction and conditions of moisture used in conjunction with the electrolytic needle.

	Electrode covered with cotton. 1 in. diam.	Electrode covered with sponge. 2 in. diam.
1. To palm	$\frac{1}{4}$ Milliamp.	1 Milliamp.
2. To forearm	1 "	2-3 "
3. To palm	sponge allowed to become comparatively dry.	$\frac{1}{2}$ "

Here it will be seen that the current obtained with a sponge electrode, after the water had been squeezed out, as always happens after a few minutes use, was reduced one-half.

It should be stated that the smaller electrode was a polished copper disc covered with absorbent cotton, one of the best conductors. While the large one was covered with chamois-skin, and its metallic surface, as I afterwards discovered, was corroded and covered with verdigris, consequently its conducting power must have been greatly impaired. I suspect that if it had been constructed like the smaller one the differences would have been still more marked. It should be mentioned that the resistance of the skin in these experiments was reduced to a minimum by the usual methods.

A variation in the strength of the current may even be produced by the needle not being inserted to the same depth in the skin. I have seen the current doubled from this cause.

Under these conditions, then, it cannot be wondered at that the effects of electrolysis are uncertain, sometimes resulting in dermatitis and scars, and sometimes in destruction of the hair alone, without the slightest disfigurement. It must be apparent to any one that, to get the best results from electrolysis, we must have some accurate method of measuring and regulating the strength of the current. This can be done by means of the *absolute* galvanometer, which, I have found, answers every purpose, and which I now always use. By its means the current can be accurately and easily regulated, and any fluctuation in its strength immediately detected. Discovering the fluctuation, it is easy to determine the cause, and to guard against its reoccurrence. The practical results obtained I have found to be far better than formerly. Pustules can be wholly and cicatrices almost entirely, even if not absolutely, avoided. When one has once used such an instrument, providing he has a reliable one, he will be loth to give it up. No small advantage is that one learns the conditions essential for a steady current, and is thus able to prevent variations. An increase of one milliampère in ordinary electrotherapeutics is of no consequence, but in such delicate operations as electrolysis, it is of the greatest consequence. A case in point will illustrate these advantages.

It is that of a young girl who had a very abundant growth of hair upon her face, necessitating repeated operations, extending on and off over a space of two years. It so happened that the skin under her jaw was very sensitive to electricity, so that electrolysis was always followed there by more or less inflammation and scars, be as careful as I would. In contrast, to this, on the sides of her face, she could bear comparatively strong and repeated currents with immunity. Under the jaw, on the other hand, only very few hairs could be done at a sitting, and that with very mild currents. Pustules, dermatitis and fine scars were frequent effects. Since using the absolute galvanometer all this has changed. I can now do what remains to be done without any secondary inflammation, and so far as I can see without any scars whatever. And I believe it to be *theoretically* possible to always remove hairs without scars. Practically it is difficult because the requisites are absolute care and great physical endurance on the part of the operator. The endeavor should be to direct the action of the current, as far as possible, to the hair bulb and follicle alone. This can only be approximated by accurately inserting the needle and using the weakest currents for the shortest period compatible with effective practical results.

But supposing an absolute galvanometer is to be employed, what rules should be observed in performing the operation; what strength of current should be employed, and for what length of time? The directions laid down by most writers are most indefinite, and do not show an intimate knowledge of either theoretical or applied principles of electricity. A late English writer, whose article lies before me and whom I quote merely to bring out the points I wish to enforce, gives the following directions: a battery of from ten to fifteen cells is to be used; the current is to pass from ten to thirty seconds until slight frothing is produced or a wheal appears around the mouth of the follicle. It is also stated that it is not absolutely necessary that the needle should be inserted directly into the follicle, as the requisite destruction occurs if the instrument be in its immediate neighborhood, and that papules and pustules result, which remain visible for some weeks.

That papules and pustules result under these circumstances can scarcely be wondered at. There can scarcely be any better way of producing them, as well as scars, than some such method as this.

The danger of relying upon the number of cells to determine the strength of the current has already been shown. Ten to thirty seconds is altogether too long for any current generated by ten to fifteen cells of a good working battery, unless a great resistance is offered by the circuit, which cannot be

known without an absolute galvanometer; and, according to the experience of the writer, a wheal should never be produced. Any current which produces a wheal, especially one that is white and sharply circumscribed, is too strong. Furthermore, I believe it to be absolutely essential that the needle should be inserted directly into the follicle and through the papilla, but not beyond if possible, if cicatrices are to be avoided.

The writer has made numerous experiments to determine what strength and duration of current gives the best results. Before stating the specific conclusions arrived at, the following general principles may be laid down. The weakest possible current of the shortest possible duration compatible with efficiency in the time at the operator's disposal should be used. If there is much work to be done, less time can be given to each individual hair. But the stronger the current and the longer its duration, the greater certainty of after inflammation and scars. On the other hand, with very weak currents, say under one-half milliampère, the time requisite to destroy the hair-bulb is too long for practical purposes, especially if there is much to be done; for the stronger the current the shorter the time needed, and *vice versa*. As a matter of experience, and as the result of numerous observations, I have found that a current of one milliampère, passing from two to three seconds, is the best. It should be not less than one-half nor more than two milliampères. With one-half milliampère it can be easily done, but takes longer. Such a current is, perhaps, to be preferred if only a few hairs are to be destroyed. With more than two milliampères pustules and scars are almost sure to result. It must be understood that the stronger the current, the shorter time must it be allowed to pass, and the greater the pain.

My plan is always to watch the needle of the galvanometer, and if it swings towards two milliampères, to shorten the duration, and if it goes beyond two milliampères to immediately break the current. I do not mean to say that it is impossible to use stronger currents without causing bad after-effects, but it is very difficult to do so, and the current must be broken almost immediately after being made. With a current of one milliampère, three seconds is amply long enough for the current to flow. This I have repeatedly determined with watch in hand. If the hair be not destroyed in that time, the reason therefor will almost always be found to be that the needle has not been accurately introduced within the hair follicle so as to hit the bulb.

Of course the stronger the current and the longer it be allowed to act the easier it is for the operator to successfully work, and hence there is always an inducement to use strong currents. If a current of one milliampère acting for three seconds will decompose the tissue within a radius of, say, 1-50 inch, for example, a current of three milliampères will decompose all the tissue within 3-50 inch, or thereabouts; and therefore with the latter current much less care need be employed in introducing the needle, as it has only to be placed somewhere near the hair, and all the neighboring tissue must succumb, hair and all, hence cicatrices.

For this reason the needle should be accurately inserted into the follicle and papilla. If it is placed simply in the neighborhood of the latter, all the intervening tissue must necessarily be exposed to the electrolytic action. Greater destruction of tissue than necessary will then be occasioned, and pustules and scars must result.

Sponge electrodes are very undesirable, as their conducting power rapidly changes as the water becomes squeezed out.

There is one more practical point which should be mentioned. The patient should never be allowed to hold the positive electrode in the hand, as is usually advised. What between the great resistance offered by the palm of the hand involving the necessity of keeping the thick dry, skin, thoroughly soaked with water, and the unevenness with which a patient presses with the electrode, it is impossible to maintain anything like a steady current. If the current hurts, the patient is sure to let up on the electrode. Under such conditions I have sometimes found it impossible to do the operation at all, the galvanometer at times marking no current and then again jumping to three and four milliampères. A large electrode, covered either with chamois-skin or a thin layer of absorbent cotton, not sponge, should be fastened to the forearm, as the most convenient place. It is hardly necessary to refer to the danger of using the positive instead of the negative pole in connection with the needle or destroying at one sitting hairs situated close together, as these points have been referred to by other writers.

The powerful electrolytic action of electricity on tissue, and the possible disastrous effects of strong and long continued currents may be seen from the following experiments, out of a number of others made by Dr. T. D. Davis,[1] some time ago, in connection with another operation. The first experiment was made with a 30 cell Grenet battery, the second with a 15 cell Bunsen battery.

(1) Two steel needles, thickness of knitting needles, were introduced into the tissue of a healthy liver within half an inch of each other. Immediately afterwards bubbles of gas commenced to issue from the cut surface of the liver, which was nearer to the points of the needles than the place of their introduction. In four minutes the needle connected with the negative pole became very loose, and bubbles of gas escaped around its point of entrance. In five minutes the needles were withdrawn, the negative one coming away easily, while the positive one, which was blackened and roughened, was firmly adherent. On cutting across the track of the negative needle, a cavity, one quarter by an eighth of an inch in diameter, was discovered, surrounded by a darkened gelatinous tissue, one-eighth of an inch in thickness. Extending from this to the point where most of the gas escaped was a mass resembling that surrounding the cavity, looking more like softened glue than healthy tissue. The track of the positive pole was black and charred, but the tissue immediately surrounding the point was firmer and whiter than in other parts.

(2) A cat was put under the influence of chloroform and the needles were introduced into the right thigh one inch apart. Soon the fizzing sound was heard, which continued until the needles were withdrawn, at the end of ten minutes. The tissue was softened around the negative and much hardened around the positive needle. The needles were then introduced into the left thigh of the same animal, and retained there for ten minutes. In the post-mortem examination, several days later, the skin on the right thigh was found ulcerated for an inch in diameter. The muscles were separated down to the heel but not to the bone. There was a cavity under the skin large enough to hold a walnut. The left thigh presented similar appearances, the cavity being as large as an egg, and the muscles separated down to the bone, as well as softened and eaten away. Part of the femur was denuded of periosteum, but not eroded.

These, of course, are the effects of powerful currents long continued, but the action from weak currents is the same in kind, differing only in degree, and these experiments show how it is possible to produce on the face irreparable injury unless care be used.

REPORT ON BACTERIOLOGY.

BY HAROLD C. ERNST, A.M., M.D., (HARV.),
Demonstrator of Bacteriology in the Medical School of Harvard University.

FURTHER investigations upon malaria by Golgi[1] have been made by the observation of forty cases mostly of the quartantype. Out of these forty cases but two gave negative results in the observation of the blood. In all the other cases the characteristic "Plasmodia" were found, the results being tabulated as follows:

I. Plasmodia only were found in the interior of the red blood-corpuscles in four cases.

II. Plasmodia and pigmented bodies in the red blood-corpuscles in eight cases.

III. Only pigmented bodies in the red blood-corpuscles in twenty-seven cases.

IV. Plasmodia in the red blood-corpuscles and free half-moon shaped, oval or circular bodies in one case.

In most of the cases there were also found the pigmented bodies described by Marchiafava and Celli.[2] In one case the plasmodia showed amœboid movements after four and one-half hours at a temperature of 9° to 10° C. The pigmented corpuscles were also seen to have amœboid movements. Golgi considers the pigmented bodies and the plasmodia (unpigmented) to be distinct, and finds the pigmented bodies to be especially characteristic of the quartan type of fever — considering the occurrence of plasmodia in this type as a complication. The quantity of the organisms found seems to bear a distinct relationship to the severity of the attack. The condition of the pigmented bodies as seen under the microscope seems to this observer to indicate the stage of the disease, and one can prognosticate the attack by observing how near complete their growth is, as indicated by their situation in the blood-corpuscles and amount of subdivision. These conclusions, however, are only applicable to the quartan type as yet.

TUBERCLE-BACILLI.

The question as to the positive diagnosis of this organism by the staining method of Koch-Ehrlich has received renewed attention.[3] The conclusions from the results thus far obtained seeming to be that occasionally the presence of organisms in fat-bearing materials, prevents the decolorizing action of nitric acid, and that therefore there may be occasions, as in the case of smegma-bacilli, where there is an imperfect application of the staining-method, and where confusion might arise. The work is not by any means complete, however, and does not destroy the value of the usual staining method for the clinical recognition of the bacilli of tuberculosis.

ULCERATIVE ENDOCARDITIS.

Wyssokowitsch[4] undertakes to produce this disease in animals by using pure culture of the organisms derived from pus in acute inflammatory conditions. The results were positive only when artificial irritation of the cardiac valve was practised. Ribbert[5] succeeded in producing ulcerative processes in the valve of rabbits' breasts by the injection of very large quantities of the staphylococcus aureus into the circulation. In an article upon the same subject by Bramwell,[6] experiments by Hare are recorded. This experimenter obtained negative results so far as the artificial production of the disease is concerned, but succeeded in obtaining from the material employed pure cultures of two organisms, one, a micrococcus resembling very strongly the staphylococcus pyogenes aureus, and the other, a short straight bacillus occurring in immense numbers. Wyssokowitsch[7] and Orth[8] have taken the subject up again, but without reaching any very definite results.

YELLOW FEVER.

Freire has published a very elaborate work containing the results of his observations upon this subject and his methods.[9] He claims to have established that the "microbe xanthogenicus" is introduced into the system by the respiratory and digestive apparatus, that from these points of entrance it passes into the circulation and thence into all the organs of the body; it is found with equal facility in the brain, muscles, kidney, spleen, pancreas, blood, lungs, urine, bile and vomit. With regard to the blood the organism is found most largely in the capillary circulation, rather than in the larger bloodvessels. The organism is very easy of detection in the urine and bile by simply placing a drop of either of these fluids upon a slide and examining with a power of from 450 to 800 diameters; blood must be treated with a weak solution of sulphate of soda before the organisms contained in it are easily visible. The period of incubation after infection is short, and the development of the organism is very rapid. The "cryptococcus xanthogenicus" appears under a diameter of 740 as minute refracting bodies, sometimes looking like black points and at other times showing a luminous spot in the center (differences of focussing). There are also yellowish masses with yellowish spots scattered about which are considered to be the scattered cells of the cryptococcus. The cells have a very rapid movement at the beginning of their development which becomes less as the cells increase in size. These cells, when mature, contain granules which are pigmented green or yellow. These finally burst through the cell-envelope and proceed to form new cells by constant increase in size. Occasionally the spores are scattered without order; sometimes they stick irregularly to the pigment, and sometimes they form regular figures, assuming shapes like a pineapple or a pear. Under cultivation the organism is found to be aërobic: it flourishes well in culture-media of bouillon, milk or gelatine solutions, forming in old cultures a yellow or even black layer upon the surface of the fluid; the ordinary temperature of the room is sufficient for its development. Methyl-violet in aqueous solution gives a very strong violet color to the cells.

Many inoculation experiments with material from yellow-fever patients — blood, urine — were practised upon animals, with the result of finding guinea pigs susceptible, whilst birds, pigeons, and chickens seemed to be refractory to the toxic effects of the organisms. The "cryptococcus xanthogenicus" was found in large

numbers in the earth of cemeteries where persons dead of yellow fever had been buried, and in the air of yellow-fever hospitals. The attenuation of the virulent strength of the organism of yellow fever is obtained by its exposure to a low temperature — 15° to 20° C. for a few days — after which exposure injections into guinea pigs produces little or no effect. The virulence may be restored by keeping the culture at from 38° to 50° C.; after a few days' exposure to this temperature, the full toxic strength returns, as proven by inoculation experiments. Acting upon these facts, Freire undertook a preventive inoculation against yellow fever with an attenuated virus.

Finding that the virulence of the "cryptococcus xanthogenicus" obtained in cold weather was less than that in warm weather, or during the time of an epidemic, he preserved cultures of the former, and used them upon man, of course being encouraged to do so by previously-completed extensive experiments upon animals. The results of these experiments seem to be favorable to his assertions, that is, that thus far, no case inoculated by him against yellow fever is as yet reported to have died of the disease.

HYDROPHOBIA.

The special interest excited in this disease by the announcement of Pasteur in regard to it has led to the endeavor, on the part of many observers, to isolate and identify the bacterium, which is in all probability the active factor in the production of the disturbance. The results thus far obtained are eminently unsatisfactory, however. Fol and Dowdeswell each think they have found a micrococcus which is the specific organism of rabies, but neither of them bring forward any evidence other than the occurrence of the bacterium in animals dead of the disease as a basis for their assertions. Pasteur himself has failed also to find anything which he is disposed to consider the "materies morbi" in this instance. Thus far there has been not only no bacterium connected with the disease, but no systematic work in confirmation of Pasteur's method of preventive inoculation has been published. Many announcements of "Pasteur Institutes" have been made in the daily press, but very little has come out with any substantial basis to it.

BACTERIOLOGICAL OBSERVATION OF WATER.

This is one of the most important of the practical applications of bacteriological science, and is being rapidly developed. A systematic observation of the limitations of chemical analysis, and the amount of evidence to be obtained in addition as to the potability of any water by the further examination by bacteriological methods, has yet to be made Such evidence would be exceedingly valuable, and it will not be long before it will be supplied. Meade Bolton [10] has paid some attention to this point, concluding that it is possible for a better decision to be given as to the safety of any given specimen of water by the employment of both methods of analysis, and in certain cases, that the observation of the bacteria and the determination of their species is the only way by which approximately exact results can be obtained.

Other first-rate recent work in the same direction is to be found in the first volume of the *Arbeiten das den Kais. Gesundheitsamte*, 1886.

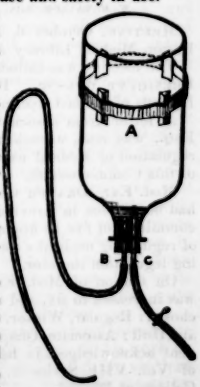
METHODS OF PRESERVING COLONIES FROM PLATE-CULTURES.

Garrè [11] suggests that the portion of the gelatine containing the colony to be kept, be cut out, and transferred with a sterilized spatula to a slide. The preparation may then be placed in a drying apparatus, or under a glass-bell, and dried to one-half or less of its original bulk. A cover is then to be fastened on with concentrated glycerine jelly. In this way, the colony may be preserved for an almost indefinite length of time for microscopic examination and demonstration.



Plaut,[12] writing upon the same subject, suggests the cutting out of the colony with fine, sterilized scissors, and its transference to a slide moistened with a very small drop of pure water. Then slight warming of the slide to settle the gelatine, but not enough to melt it, and finally, covering the whole with a cover-glass fastened by a ring of dammar-lac, the advantages claimed for this method being that the colony is not only preserved for microscopic examination, but may also be used to propagate future cultures by the simple melting of the dammar-lac with a heated needle, and the removal of the cover-glass.

New Instruments.

A SIMPLE APPARATUS FOR WASHING OUT THE BLADDER.

BY FRANK HOLYOKE, M.D., HOLYOKE, MASS.

THE accompanying diagram illustrates an apparatus for washing out the bladder, which combines cheapness in construction, with ease and safety in use.

An eight or twelve ounce, glass bottle, A, has its bottom cut off; and a cork perforated by two glass tubes, is now introduced and sealed, to prevent leakage of air or water. To the glass tube, B, by five feet of rubber tubing, is attached a rubber catheter. To the evacuating tube, C, is attached one foot of rubber tubing clamped by a bull-dog forcep or patent clothes-pin.

This safety of this apparatus lies in the fact that the evacuating tube reaches within the neck of the bottle one-half inch beyond the injecting tube, so that, when held upright, there is no possible chance, while emptying the bottle through the former, for air to enter the latter.

Four pieces of cork held at regular intervals by a narrow rubber band prevent the bottle from rolling off the table, while the patient — either standing or seated — introduces the catheter; upon the entrance of which within the bladder the bottle is held as represented and brought below the level of the bladder. The

[11] Fort. d. Med., 1886, S. 392.
[12] Fort. d. Med., 1886, S. 419.

bladder being thus emptied, the forceps is removed from the evacuating tube, and all the urine passes into a vessel except the half-thimbleful that remains in the neck of the bottle, to guard against the entrance of air within the injecting tube.

The clamp is now replaced and the fluid to be used for injection is poured into the bottle which is slowly raised to a proper distance above the bladder, which gradually fills; the operator readily observing through the glass that it be not raised so high that the level of the fluid falls below the end of the glass tube, B.

Having once introduced the catheter, this process of filling and emptying may be repeated as often as desired, without laying down the bottle, by the careful raising and lowering of which, the distension of, and pressure within, the bladder, may be regulated.

This instrument I made for a man who recently came under my care, suffering with chronic cystitis. He declares that it is easily managed and practical:— for in this apparatus we have no syringe, no tap to turn, no injecting nozzle which has to be repeatedly connected and disconnected with the catheter, and no doubt about its safety, for we see what we are doing.

A ready way to remove the bottom of a bottle is to file a groove, with a three-cornered file wet with turpentine, deep enough to hold in place a piece of strong twine. The twine is then drawn to and fro until the glass becomes hot. If now the bottle be immersed in cold water, the bottom separates along the filed groove.

Reports of Societies.

MASSACHUSETTS MEDICO-LEGAL SOCIETY.

W. H. TAYLOR, M.D., RECORDING SECRETARY.

MEETING, October 6, 1886, at the rooms of the Boston Medical Library Association.

The meeting was called to order at 12.30, P. M., by PRESIDENT WINSOR. Present, eighteen members. Records of the last meeting were read and approved.

A letter from associate member H. W. CHAPIN, ESQ., was read, advocating some movement toward regulation of medical expert testimony in the courts of this Commonwealth.

Med. Exr. DRAPER made some remarks on what had been done in previous efforts, and moved that a committee of five be appointed to consider the subject of regulating medical expert testimony, and of obtaining legislation therefor.

On motion of Med. Exr. HOLMES, this committee was increased to six, and the following members were chosen: Regular, Winsor, Chairman, Draper, Gleason, and Holt; Associate, Chaplin and Tyndale. The President acknowledged, in behalf of the Society, receipt of Vol. VIII, Series 3, of the Transactions of the College of Physicians of Philadelphia.

Med. Exr. HOLMES read a paper on the case of Carrie Whitney, of Boston, found dead in his district. The ligamentum nuchæ was ruptured, and Dr. Holmes believed that death was due to hæmorrhage into the spinal canal, with pressure on the cord. There was no mark of external violence. The specimen was exhibited, and some discussion took place.

DR. DRAPER reported a case where the ligamentum nuchæ was ruptured, with fracture of transverse processes, and separation of spinal processes of the vertebræ. Death was due to spinal hæmorrhage and pressure on the cord. The nature of the accident was known, though there were no marks of external violence.

DR. PRESBREY reported a case of spinal hæmorrhage and death from a blow of the fist under the ear.

Cases more or less similar to that of Dr. Holmes were reported by various members.

Med. Exr. TOWER reported a case of poisoning by two ounces of commercial hydrochloric acid, taken with suicidal intent. There was pain and vomiting, and purging of blackish-brown and bloody matters. The mucous membrane of the stomach was thoroughly cauterized, and was black in color.

Med. Exr. ADAMS reported the appearances in a case of alleged rape of a child ten or eleven years of age, and also narrated a case to show the fallibility of the sign of alcoholic odor in the breath in cases of alcoholic poisoning.

NEW YORK STATE MEDICAL ASSOCIATION. FIFTH DISTRICT BRANCH.

SECOND Annual meeting, held at Everett Hall, Brooklyn, October 12, 1886.

MORNING SESSION.— THE PRESIDENT'S ADDRESS

was delivered by DR. J. G. PORTEOUS, of Poughkeepsie. In it he congratulated the Branch and the parent Association on the flourishing condition of the organization, and paid a tribute to the illustrious dead of the year, Drs. Austin Flint, Frank H. Hamilton, and Desault Guernsey, the latter being President of the Fifth District Branch at the time of his decease.

DR. JOSEPH C. HUTCHINSON, of Brooklyn, read a

BIOGRAPHICAL NOTE OF THE LATE DR. FRANK H. HAMILTON.

DR. AVERY SEGUR, of Brooklyn, read a paper on

SOME RECENT IMPRESSIONS OF MEDICINE IN ENGLAND,

in which he spoke of the history of the Royal College of Physicians and the Royal College of Surgeons, the study of Medicine in England, the qualifications required for licensed practitioners and those entitled to the degrees of Doctor or Bachelor of Medicine, the clinical advantages afforded by the great London hospitals, the Croonian, Gulstonian, and Lettsomian Lectures, and the many advantages enjoyed by the profession in Great Britain, as exhibited in the British Medical Association and its Branches.

AFTERNOON SESSION.

DR. H. A. POOLER, of Goshen, Orange County, read a paper on

THE MILK SUPPLY OF LARGE CITIES AND THE IMPROPER MODE IN WHICH IT IS CONDUCTED.

Having spoken at considerable length of good cow's milk, and in what respects it resembled and differed from human milk, he referred to the abnormal conditions of milk. There was only one period, he said, at which a healthy cow will secrete unhealthy milk, and that is after parturition, when it contains colostrum. Such milk taken by the young or invalids, might produce very harmful results. It is certain that the milk would not be entirely free from these cells ten days after the birth of the calf; but the farmer, not

knowing the pathological condition of the milk at such a period, or at least the length of time that it is affected, usually saves the sixth milking, which occurs only three days after parturition. The milk of the entire dairy may thus be contaminated by the diffusion of the colostrum through it.

In speaking of the adulteration of milk, he said that many foreign substances have been added to it, but by far the most common forms of adulteration are the removal of fat and dilution with water. Pure milk furnishes an indication of the amount of fat required by the human being in the large proportion of butter fat to its other solid constituents which it contains. Besides performing certain purely mechanical offices, fat is essentially concerned in many of the chemical and vital processes of the body. It forms the nucleus of all cellular growth, renders important assistance to the digestive fluids in the digestion of other principles, is actively concerned in exciting the changes that take place in the nitrogenous principles, and has much to do with the formation of bile and blood; while fatty matter forms a great part of the brain, and the entire nervous system. As a heat-producer, fat also stands pre-eminent, and it is mainly from the fat stored up in the body that sustenance is derived when the supply is temporarily cut off or the power of digestion is impaired by sickness. Furthermore, it is believed that nature has especially adapted butter fat to the digestion of infants. Altogether, therefore, it is essential in large quantities to the proper nutrition of young children.

Dr. Pooler then quoted as follows, from the report of Professor C. F. Chandler (made with the assistance of C. E. Munsell, Ph. B.), published in the second annual report of the New York State Board of Health (1881–82): "While a large proportion of the milk sold has been but moderately watered and skimmed, and is still above the standard of the poorest milk (two and one-half per cent. of fat), much of the milk has been *extended* and skimmed far below this standard. So openly are these frauds practised that 'creameries' have been established in many localities, the names and locations of seventy-three such establishments being known to the writer; of which sixty-three are known to send skimmed milk to New York City, all of which is sold as whole milk on its arrival." Later reports of C. E. Munsell, Ph. B., showed, from analysis, that this skimming amounted to from about 29 to 78 per cent. of the fat. Now, said Dr. Pooler, you can readily see that the mother receives this milk into her home as whole, pure milk, and dilutes it one-half to three-fourths. What then does the child have to live upon, when nature says that infants must have 3.38 per cent. of milk fat for their sustenance and development.

Up to 1883 there was no law in the State prohibiting the shipping and sale of skimmed milk; but the passage of such a law was then secured, and milk inspectors were placed upon the milk trains. Dr. Pooler told the Judiciary Committee of the Legislature that if they would pass the law, he would guarantee to reduce the mortality among young children in the city of New York at least three thousand, and he was able to keep his promise. In 1879 the mortality in children under five years was 12,777, or about 50 per cent. of the births of that year. This was before the milk adulterators carried on their work so extensively as afterward. In 1880, however, the mortality in this class increased to 14,650, and while from 1878 to 1879 it increased only 300, the increase in the number of deaths from 1879 to 1880 was 2,000. The mortality in 1881 was 17,737, an increase of 3,000 over 1880, and about 75 per cent. of the births. In 1882 the number of deaths was almost the same as in 1881; but if it had not been for the work that was done in the autumn of 1882, the mortality would have reached nearly 20,000; a close watch being then kept upon the dealers. In the winter of 1882 and 1883 the skimmed-milk bill was passed and enforced, and notwithstanding many discouraging circumstances the mortality was reduced from 17,737 in 1881, and 17,520 in 1882, to 13,856 in 1883, a reduction of some 4,000.

But, unfortunately, in 1884 the good work was interfered with by the politicians. Up to this time the labor performed had been almost all voluntary services. An appropriation was therefore asked from the Legislature; but while this was granted, a Dairy Commission was also appointed to take charge of it, and this commission was manipulated so as to form a part of the great political "machine." There were other political changes also, and the withdrawal of Professor Chandler from the head of the Metropolitan Health Department, an irreparable loss. Hence the mortality in children under five years increased from 13,865, in 1883, to 15,272 in 1884, an increase of nearly 2,000. Dr. Edson, of New York, and Dr. Bartley of Brooklyn, had, however, done all in their power, with the means at their command, to keep the evil in check, though the small force available for this service was quite inadequate to the demands upon them.

Dr. Pooler spoke next of the adulteration of milk through the cow, by feed and otherwise. The refuse of about nine thousand distilleries, breweries, and malt-houses in this country is nearly all sold to feed the cows that produce the milk upon which the infantile population principally subsists. The natural food of the cow is grass, either green or dried, and when she is fed exclusively upon it, her fresh milk is generally neutral in reaction. On the contrary, the milk of cows fed, either wholly or in part, upon food other than the natural is almost invariably acid. Dr. Mayer, of Berlin, found the following results: "Of cows fed with brewers' grains, red potatoes, rye bran, and wild hay, in five instances the milk was slightly sour, in one, very sour. Of forty cows fed with potato mash, barley husks and clover, and barley straw, in ten examined the milk was sour, in three very sour. From five cows fed by a cow-feeder on luke-warm bran-mash and hay, in four the fresh milk was quite neutral, in one it was decidedly alkaline."

All physicians know how easily affected infants are by acid milk, and Dr. J. Lewis Smith, in his work on diseases of children, says that milk used for children should always be alkaline. If it is acid, as shown by the proper test, it should be rejected. Dr. Hassal, in his standard work on "Food and its Adulterations," says: "As is well known, a very considerable number of the cows which supply London with milk, are kept in various confined and unhealthy places in the metropolis. Such cows are seldom turned out to grass; the system adopted being altogether artificial and unnatural. Brewer's grains and distiller's mash form much of their food. These stimulate the animals unnaturally, and under this stimulus larger quantities of

milk of inferior quality are secreted. The cow quickly becomes worn out and diseased in consequence. It has been shown also by experiment that brewer's grains afford a most favorable soil for the development of the microbe of anthrax, and in 1879 an outbreak of this disease occurred in England, in a district which had previously been free from it, where it was found upon investigation that all of the cattle infected had been fed upon grains from one particular brewery.

The facts show that the action of brewer's grains is to impoverish the milk in its most essential constituent, and largely increase its most objectionable ingredient, caseine. When the fat is not equal to the normal amount, the milk forms a hard curd in its coagulation, which is known to the skimmed-milk cheesemakers as "hickory curd"; the formation of this being directly due to the abstraction of fat. It is the cheapness of the brewer's grains, together with the large amount of milk which the cows give when placed upon them that induces farmers to purchase this food. The proper food, wheat-middlings or wheat-bran, costs twenty dollars a ton, and will yield less milk (though of far better quality), than a ton of brewer's grains which costs only from four to six dollars. Dr. Pooler also spoke of the evils resulting from the transportation of milk from long distances. (Dr. Pooler was assisted by E. W. Martin, Ph. D., Chemist to the New York Board of Health, who projected upon a screen a number of fine micrographic illustrations).

In the discussion which followed the reading of the paper, Dr. A. N. Bell said that if he was correctly informed, milk from diseased cows not infrequently contains a large amount of fat, and that this was particularly the case with milk from animals suffering from rinderpest. We must be on our guard, therefore, against this source of danger also.

DR. ALFRED L. CARROLL, of New Brighton, Staten Island, read a paper on

LEPTO-MENINGITIS INFANTUM.

The clinical history and pathology of acute hydrocephalus, he said, are involved in considerable obscurity; the symptomatology varying, on the one hand, in cases having a similar morbid origin, or, on the other hand, closely corresponding in instances due to different kinds of lesions. It seems to be the general opinion that recovery from a meningeal attack in childhood precludes the idea of tubercular deposit; but whether non-mortal forms of acute hydrocephalus (not secondary to disease elsewhere) are always dependent on inflammation of the pia, or whether there may be other less serious pathogenetic factors, is a question still open to discussion.

Huguenin, in Ziemssen's Encyclopædia, affirms that cerebral hyperæmia is the exciting cause in all instances save those occurring in marasmic conditions supervening upon chronic digestive disorders; and in these, forced to admit an anæmic state of the brain, he assumes "partly a hydrocephalus *ex vacuo*, in consequence of the diminution of the brain, partly the result of the long-continued weakness of the circulation, with greater emptiness of the arteries than of the veins." In the former class of cases he intimates that we are forced to assume a true inflammatory process as the cause of the effusion into the ventricles, but at the same time states that it is impossible to say, during life, when the hyperæmia ceases and the inflammation begins. But in his description of the pathological anatomy it is admitted that the pia contains a moderate amount of blood, or is anæmic; no traces of arterial hyperæmia can be found. We are forced to assume that it disappeared at the moment of death.

J. Lewis Smith, describing tubercular and simple meningitis conjointly, speaks of the "inflammatory action" as usually confined to the pia mater, and includes purulent meningitis of the convexity apparently as a more intense form; adding that serous distension of the lateral ventricles is a common result in either variety of the disease. Vogel, on the contrary, asserts that acute hydrocephalus never occurs in combination with simple meningitis, but invariably supervenes upon tuberculous meningitis.

Other authors either deny a non-tubercular origin of acute hydrops of the ventricles, or, at all events, ignore the affection which Huguenin endeavors to differentiate; an affection of which well-defined examples are not unfrequently encountered, but wherein we are asked to "assume" an ante-mortem hyperæmia which suddenly changes to a post-mortem anæmia, and an inflammatory process which does not leave behind it the ordinary traces of inflammation.

As regards the first of these assumed phenomena, all pathological investigations tend to show that we are much more likely to be misled by a post-mortem fulness of the intra-cranial vessels where previous anæmia has existed than to fall into the opposite error. Long ago, the classical experiments of Kussmaul and Tenner (New Syd. Soc., Vol. V.), led them to the conviction that, "from the quantity of blood contained in the skull after death, it is seldom possible to draw certain conclusions with respect to the quantity contained during life"; and Moxon (Croonian Lect., on the Influence of the Circulation upon the Nervous System, 1881), states that, "no degree of redness or pinkness, or overfulness of blood about the brain or its membranes can prove that there was any morbid state of circulation within the head before the act of dying."

On the other hand, although the mere so-called "determination" of blood, caused by local irritation, may speedily pass away, the evidences of inflammation are usually regarded as persistent and unmistakably recognizable after death. And these evidences lie, not in simple fulness of the larger vessels, but in the crowding of the smaller ramifications with coherent corpuscles, even in an early stage of the inflammatory process, whilst in a more advanced condition exudation-products are discoverable. In inflammation of the pia of undoubted character, this membrane is lacerable and infiltrated; the arachnoid thickened and opaque; fibrinous exudation being marked. In the disease described by Huguenin, there is no effusion between the dura and pia, nor in the meshes of the latter, the outer surface of which is "usually remarkably dry"; there is no exudation at the base; the ependyma of the ventricles shows no change, macroscopic or microscopic. The only significant morbid appearance is a turgescence of the choroid plexuses, sometimes with punctiform extravasations. In brief, we have to deal with a disorder of which the pathological features are more or less rapid accumulation of fluid in the ventricles, with a specified morbid condition of the choroid plexuses; its clinical manifestations (by no means uniform), convulsions, unconscious-

ness, paralytic symptoms, and disturbances in the tract of the pneumogastric and splanchnic nerves.

The known causes of serous effusions are usually found in anæmic conditions, or in mechanical impediment to the return of venous blood. Thus, dropsies of different sorts are common in the hydræmia or "hypalbuminosis" of general anæmia; from malarial cachexia; from feebleness of circulation in dilatation of the left cardiac ventricle; from aortic insufficiency; from pericardial adhesions; or, on the other hand, from valvular insufficiencies in the right heart, or any intermediate cause of capillary and venous stagnation. Within the cranium, such stagnation is especially likely to concur with arterial anæmia, since, even allowing for the balance ordinarily maintained by the ebb and flow of the cerebro-spinal fluid, atmospheric pressure tends to retard the egress of venous blood. Moreover, the outlet from the choroid plexuses, through the venæ Galeni and straight sinus, has the additional obstacle of a rectangular diversion at the torcular Herophili. It has long been known that in animals bled to death the intra-cranial vessels may retain their contents after all the rest of the system is drained. Meningeal venous turgescence of this kind, "ex vacuo," is familiar as arising from atrophy of the brain, and in other conditions associated with arterial anæmia. Furthermore, the pia gradually diminishes in vascularity from the convexity toward the base, until, at the crura and pons, it is almost devoid of vessels. Finally, we have the authority of Nothnagel for doubting whether active hyperæmiæ can limit themselves to circumscribed regions of the brain; whilst localized ischæmia about the basal ganglia is a more probable event, originating in arterial spasm, reflected irritation, or insufficient cardiac action.

Having devoted considerable attention to the phenomena and mechanism of effusion into the ventricles, Dr. Carroll went on to say that as to the clinical phenomena of acute hydrocephalus, it is well known that convulsions are oftener due to cerebral anæmia, rapidly induced, than to any mechanical alteration of pressure upon the brain. Epilepsy is commonly conceded to be of anæmic origin, and Moxon has observed that in this disease the convulsive seizure is often preceded by a momentary arrest of the pulse.

Niemeyer affirms that "the so-called symptoms of pressure in apoplexy, tumors, the various forms of hydrocephalus, and other diseases encroaching on the intracranial space, are not immediately referable to the pressure on the brain substance, but to the consequent anæmia," and he farther points out the false interpretation usually given to increased pulsation of the carotids, which he defines as an essential consequence of cerebral anæmia.

Another common mistake is to regard the vascular appearance of the external surface of the head and face as indicative of the intra-cranial condition. In states of general anæmia, facial pallor and cerebral anæmia are twin results of the same cause; but when the blood is pumped up toward the head in due amount, a localized ischæmia within the skull is apt to divert an increased flow into the external carotid and those branches of the internal carotid which arise before its entrance into the cranial cavity.

It is extremely difficult to discriminate during life between this, so to speak, idiopathic leptomeningitis and other meningeal affections of childhood. In early infancy, and after exhausting disease, the secondary "hydrocephalus ex vacuo" is to be considered rather as a mode of dying from other complaints, and the past history of the case (oftenest one of protracted diarrhœa) will afford a clue to its nature. True meningitis, commonly affecting the lateral part of the convexity, arises by traumatism or extension from adjacent foci, as in internal otitis, caries of the cranial bones, mastoid inflammation, phlebitis sinum, etc., and although in most examples its diagnosis may be made with some confidence, it is well to know that not a few cases occur in which the symptoms simulate those of acute hydrocephalus.

Having briefly referred to his extensive post-mortem experience, which, he said, had induced him to believe that tubercular meningitis seldom if ever occurs except as a part of a more generalized deposit, and that the majority of the cases ascribed to this cause in death certificates, but not verified by necropsy, are really examples of Huguenin's leptomeningitis, Dr. Carroll summed up his argument by saying that he was convinced that a malady quite frequently occurring in childhood, and often erroneously reported as tubercular meningitis; characterized by serous distension of the ventricles, and variously described under the names of "simple meningitis," "leptomeningitis," and "acute hydrocephalus," but by most writers ascribed to hyperæmia and inflammation, is, on the contrary, essentially due to cerebral anæmia; that the principal and most significant morbid factor is a varicosity of the choroid plexuses, sometimes extending to those of the fourth ventricle, exerting Moxon's "stop-cock" action, perhaps, in many cases, and thus aggravating the arterial anæmia which gave it birth.

In conclusion, he submitted a microscopic preparation exhibiting the condition of venous and capillary stasis met with in these cases.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated meeting, October 18, 1886.

PRESIDENT'S ADDRESS.

On calling the Association to order, the President, Dr. Charles H. Leale, made a brief address on the resumption of the active work of the Society after the long summer vacation, concluding his remarks with a feeling allusion to the death of Professor Hamilton, which had occurred since the last meeting.

RESOLUTIONS ON THE DEATH OF DR. FRANK H. HAMILTON.

The Vice-President, Dr. John Shrady, offered the following resolutions, which were unanimously adopted:

Whereas, It has pleased the Almighty Disposer of Events to remove from the sphere of his usefulness our much-respected co-worker, Frank Hastings Hamilton, M.D., LL.D., and

Whereas, The New York County Medical Association desire to express a sense of their bereavement, in common with the many organizations with which he was connected; therefore, be it

Resolved, That the fulness of his days has been a record of a well-spent life; and that his work has adorned the surgical annals of America, borne his name beyond the borders of our hemisphere, and added to the solid contributions of medical literature.

Resolved, That as a scholar in his chosen science,

he has won a place among the worthies of all tongues; and that he has conscientiously weighed all his statements, and given to the world the results of a ripe experience and a most painstaking discrimination.

Resolved, That his professional life has been gauged by the strictest regard to the right; that his loyalty, ever unimpeached, was never expended upon the unworthy, nor his unswerving rectitude ever challenged, even by the captious multitude.

Resolved, That the memory of his many virtues will ever linger with us, and that we tender to his family our sympathies, assuring them that his humanity, his sterling merit, and his valuable counsels have not been unappreciated by those who had the honor of association with him.

DR. FREDERIC S. DENNIS read a paper on

SOME POINTS OF SPECIAL INTEREST IN THE TREATMENT OF COMPOUND FRACTURES, INCLUDING A REPORT OF OVER FIVE HUNDRED CONSECUTIVE CASES.

He said that in compound fractures, while absolute cleanliness is essential, and extension necessary, the rule should be adopted that no fixation apparatus should be allowed to remain in position longer than eight days without an inspection of the parts. Otherwise, the result might not be satisfactory, and he gave some illustrative instances. The seat of fracture should be inspected at the end of eight days, and then at ten days, after which the dressing could be allowed to remain untouched as long as was required. He said he was more and more convinced, as time went on, of the great importance of the first dressing in compound fractures, and this should be made with the same care and attention to detail as in cases of resection of bones or laparotomy. The treatment consisted, first, of securing perfect asepticism; and second, of the application of an appropriate plaster-of-Paris support. For some time past he had instructed the ambulance surgeons in his service at the 99th Street Reception Hospital, to make antiseptic irrigations, and apply antiseptic dressings in all cases of compound fractures before lifting the patient into the ambulance, and the results thus secured had been extremely satisfactory.

Dr. Dennis then went on to call attention to a number of points which had especially interested him in connection with the treatment of this class of fractures. The first of these was

(1) *Meningeal Hæmorrhage.* In cases of fracture of the skull, when this occurred, it had hitherto been the common practice among surgeons to ligate either the common or the external carotid artery. In a number of instances, however, he had been successful in controlling the hæmorrhage without resorting to this procedure. In the first of these cases that he referred to, he removed the bone to the extent of about six inches, and endeavored to grasp the middle meningeal artery with the forceps. On account of the receding of the dura mater, however, he was unable to accomplish this until he ran a tenaculum through the dura, and then brought it out in such a way as to include and raise the lacerated and bleeding vessel with it. By this means, he was enabled to apply the artery forceps and perform the ligation with facility. This procedure might, perhaps, be regarded as quite bold, but the results showed that it had accomplished a great saving of life, when the former statistics were brought into comparison. In connection with this point, Dr. Dennis presented some specimens, showing that a meningeal hæmorrhage might be produced by *contre-coup*.

(2) *Fat Embolism.* Having mentioned that the attention of the profession was first called to this condition by Wagner and Zenker, he gave a *résumé* of the researches of various authors concerning it. While fat embolism was usually fatal in connection with fatty liver or tuberculosis, it was usually by no means so serious a complication when met with in compound fractures. He briefly described the symptoms, which, in general, resembled those of secondary shock, and a prominent feature of which was the frequent occurrence of Cheyne-Stokes respiration. In several cases he had found an abundance of fat globules in the urine. Fat embolism was said to be more frequent in the aged than in younger subjects. Having pointed out the differential diagnosis between this condition — secondary shock and pulmonary embolism — and stated that one of the principal points in this was the matter of time (fat embolism always occurring within three days), he spoke of the treatment. This consisted in the administration of ether, on theoretical grounds, for the purpose of dissolving the fat, and of appropriate stimulants. Dr. Dennis said that he had now under treatment in Bellevue Hospital a case of fat embolism, which had occurred in connection with a simple fracture of the fibula. Two days after the accident, the patient was suddenly seized with great dyspnœa and depression, and the temperature ran up to 104°, while the urine was found loaded with fat globules. Under the administration of Hoffman's anodyne and carbonate of ammonia, the patient became relieved, and her condition was now favorable.

(3) *Insanity following fracture.* While insanity was sometimes undoubtedly due to traumatism, it was usually a difficult thing to trace it to a fracture of the skull. He had, however, seen some such cases. In one of these, the patient, he was informed, was now hopelessly insane. In another, idiocy and imbecility resulted. In one in which constant severe headache, accompanied by more or less mental aberration, followed such a fracture, he trephined the skull, and the patient was cured. In three cases of traumatic epilepsy, in which there was more or less disturbance of the mind, he also effected a cure by trephining. He expressed the positive conviction, however, that in epilepsy there is little to be expected from trephining except in cases where there was well-marked depression. Having referred to a number of successful cases from trephining performed by other surgeons, he spoke of the importance of always raising a depression of the skull as soon as possible after the reception of the injury, whether there are any symptoms due to the depression present or not. By such a procedure the patient might be saved from becoming insane in the future.

(4) *Malignant disease.* Dr. Goss had pointed out that about one-half of all the cases of malignant bone-disease could be traced to traumatism, and Dr. Dennis said that he had been able, in quite an extended experience, to verify the correctness of this view; although it was not often easy to trace such disease to fractures. Sarcoma was the variety of malignant growth that usually resulted from traumatism. Epithelioma might also develope indirectly; but this almost always arose in connection with a sinus leading down to the bone. When malignant disease occurred, he advised early

amputation, and in illustration he referred to a case of sarcoma of the femur which was sent to him by Dr. Robb. The patient refused to submit to amputation until the growth had become very extensive, and he did not survive the operation. The specimen was exhibited and showed an enormous growth of the malignant disease.

(5) *Tenotomy.* Two years ago he said he had called attention to the value of tenotomy, in many instances of compound fracture, and since then he had met with a considerable number of cases which had further confirmed him in this opinion. While it was of great utility in all oblique cases in which there was difficulty in reduction, it was of no avail in vertical fractures. He had practised it not only on the tendo achillis, but also on the hamstrings and the tendons of the arm and forearm.

(6) *Healing by Schede's method.* Fluid blood and blood clots, he said, if perfectly aseptic, were undoubtedly valuable aids to hastening and perfecting repair by primary union; but if rigid antisepsis was not carried out, they might be a source of very great danger. This was no doubt the reason why this method had not been adopted earlier; as it was only since the days of antiseptics that it had become practicable.

(7) *Amputation.* Formerly, amputation was resorted to in a great majority of all compound fractures admitted to large hospitals, as this was necessary in order to prevent blood-poisoning. In Bellevue it was resorted to in every serious case; and a fracture into the ankle or knee-joint was regarded as affording a certain indication for amputation. But now the case was entirely different; and the loss of a few inches of the shaft of a bone, (although there might be some permanent shortening), did not justify amputation. The limits for this were now exceedingly narrow and contracted; and this fact he considered one of the greatest advances in modern surgery. When amputation was found to be necessary, it was proper to defer the operation for several days in cases where great shock was present; while formerly this would not have been possible without subjecting the patient to the greatest possible risk. It was important, however, in such cases, that no dressing should be applied or compression made above the seat of injury, on account of the danger of inducing dry gangrene.

Dr. Dennis next proceeded to present an analysis of his cases, which were 516 in number. Of these, 107 were fractures of the skull, and of the latter 47 proved fatal. 39 of the patients died, however, within the first 48 hours. The special circumstances attending the death of the remaining 8 were referred to singly. There were 15 cases of fracture of the arm; of which 14 recovered, and 1 died. The latter was a severe case of railway injury, and death ensued within 48 hours. 23 were cases of fracture of the fore-arm, of which 22 recovered, and 1 died. This death occurred within 24 hours. 53 cases of fracture of the thigh; of which 48 recovered, and 5 died. All the deaths occurred within 48 hours. 150 were cases of fracture of the leg. Of these, 15 cases required amputation. This left 135 cases; of which 122 recovered. Of the remaining 10, 2 were transferred from the hospital at the request of the patients, immediately after their reception, and the 8 others died; all of them within 48 hours. 37 were fractures of the hands and feet, and these were all accompanied by much damage to the soft parts. One case died from other injuries, and the rest all recovered. 23 were fractures of the shoulder, elbow and wrist, and all recovered. Of fractures of the hip, knee and ankle, there were 40 cases; 4 of which required amputation, and 3 of which proved fatal. In none of the latter was septicæmia the cause of death. 24 were fractures of the carpal, metacarpal, tarsal, and metatarsal bones, and all recovered. 28 were fractures of the upper and lower jaws, and these also all recovered. 13 were fractures of the ribs and nasal bones, and 1 of them died, within 36 hours. In addition, there was 1 case of fracture of the ilium, and 2 of the malar bones; all 3 of which recovered.

In the 516 cases, there were thus: 59 deaths, 19 cases requiring amputations, and 2 cases in which, owing to removal from the hospital, the result was unknown. Of the 59 fatal cases, 49 died within the first forty-eight hours, or during the period of shock, and, therefore, before any plan of treatment could be adopted. Of the remaining 10, one died of tubercular meningitis (the autopsy showed that there was no septic trouble); one died of uræmic poisoning from Bright's disease; and of the others only two could be attributed to septic infection of the wound. One of these patients, who had compound fracture of the skull, died fifty-three hours after trephining, and the other was a man over sixty years of age, whose foot was very badly crushed.

Dr. Dennis then quoted some of the statistics of compound fractures, gathered from the best authorities, before the introduction of antiseptics. According to Norris, at the Pennsylvania Hospital from 1839 to 1851, there were treated 116 cases of compound fractures of the leg and thigh (excluding those in which amputation was resorted to), with 51 deaths, or a mortality of 44 per cent. In the New York Hospital, about the same period, there were 126 cases, with 61 deaths, or a mortality of 48 per cent. In the German hospitals, a decade later, the mortality was 31 per cent., while in St. Petersburg it was no less than 68 per cent. In Guy's Hospital, London, from 1841 to 1861, the mortality was 26 per cent. According to the most reliable tables, therefore, the number of deaths was from 26 to 68 per cent.

After the introduction of antiseptics there was a wonderful difference. The death-rate fell from 68 to 4 per cent. In Bellevue Hospital, among 224 cases of compound fractures of the extremities (exclusive of amputations) such as the other statistics were based upon, there were but 11 deaths, or a little over 4 per cent. Now, taking Dr. Dennis's cases, there was not a single instance among the fractures of the extremities of death, from septipyæmia. Pyæmia and septicæmia could, therefore, be said to have been eliminated as a cause of death in these cases. This great result was due to the science of bacteriology, and for such a triumph the profession was indebted to Sir Joseph Lister, whose name could never be dissociated from the march and progress of surgery.

Dr. F. Van Fleet exhibited the specimens from, and made some remarks upon a case of

ABSCESS OF THE BRAIN FROM SUPPURATIVE OTITIS.

The chief point of interest was that if the ear-trouble had been properly attended to in the beginning, the abscess, which was located in the left hemisphere of the cerebellum, would probably not have developed, and the child's life thus been needlessly sacrificed.

AMERICAN ACADEMY OF MEDICINE.

ANNUAL MEETING AT PITTSBURGH, OCTOBER 12TH AND 13TH, 1886.

THE annual meeting of the American Academy of Medicine was held in Pittsburgh, Penn., on Tuesday and Wednesday, the 12th and 13th of October, three sessions being held on the first and one on the second day.

This Association has for its principal objects the elevation of the standard of medical education, and the persuading of young men who propose studying medicine to prepare themselves by a full collegiate course. The membership is substantially limited to those doctors of medicine who have earned a degree in arts or science. Last year a number of amendments to the constitution were offered, all looking to an enlargement of the membership by accepting those who are not A.B.'s, but have distinguished themselves in the profession, and much of the interest of this year's meeting centred about these propositions, which, under the usual rule, had been lying over for a twelve-month. The action of the Society, however, showed that there is at present no considerable desire to alter the conditions of fellowship, for all the proposed amendments were laid on the table till next year, when they will be again discussed. There is no disposition in the Academy to attempt to establish in the profession an aristocracy based upon the circumstance of early advantages, but it is thought wise to enlist the sympathies of a much larger number of college-bred men before endeavoring to make the membership general.

Most of the papers presented were on topics within the special scope of the Academy's work, but several strictly scientific articles were read.

DR. RICHARD J. DUNGLISON, of Philadelphia, made a report on the present working of laws regulating medical practice. The various States furnished their contributions to the material of this paper, which showed clearly the formal attitude of the people in different parts of the country towards the profession. The influence of legislation in one State upon the physicians of neighboring States was strikingly portrayed, as, for instance, where the stringent law of Illinois results in the flooding of surrounding commonwealths with the charlatans which flee from the wrath of Rauch. The report was so full of details as to forbid anything like a brief abstract, and must be read in full to be appreciated.

DR. FREDERIC H. GERRISH, of Portland, read a paper on the best equipment for medical study. The Academy advises a collegiate course, but the curriculum varies so widely in different institutions that it is desirable that the studies best adapted to the preparation for medical study should be pointed out in order that a selection may be made, as is possible in so many of the colleges of to-day. The essayist advocated the study of English, Latin, French and German, mathematics, physics, chemistry, botany, zoölogy and logic. He insisted that these branches should be pursued in a thoroughly practical way; for example, the student should learn to speak the modern languages, and should study the physical sciences in the laboratory, and not merely from the text-book. The analysis of chemical substances and of botanical specimens was considered a peculiarly good training of the mind in the direction of diagnosis by exclusion, the only safe method of determining the character of a disease.

DR. R. LOWRY SIBBET, of Carlisle, Pa., read a paper on the two standards, literary and medical, advocating the necessity of a degree in arts and a degree in medicine, as the only presumptive evidence of entire qualification for medical practice.

DR. L. P. BUSH, of Wilmington, Del., made a strong argument on the advantages of a classical education to the medical student and the physician. The discipline resulting from such training was claimed to prepare the mind particularly well for the pursuit of medical study. The thought was developed in a graceful and attractive style, which won the admiration of all.

DR. PHINEAS S. CONNER, of Cincinnati, presented an essay on the medical service of the United States Pension Bureau. While admission to the medical department of the army and navy is possible only after an examination far more severe than that which is required in any medical college in the country, and the Marine Hospital Service exercises similar care in the selection of its surgeons, the medical work of the Pension Bureau is committed to hundreds of physicians all over the country, whose appointments are strictly political, and whose professional qualifications are made the subject of no particular investigation. And yet these men have to deal with many times more cases of disease and injury than do the surgeons of army, navy, and marine hospitals together, and these cases are of a character to demand the most profound learning, the widest experience and the greatest acumen. Dr. Conner proposed the establishment of a medical corps of highly educated men, limited in number, which should devote itself entirely to pension work.

DR. VIRGIL P. GIBNEY, of New York, read a paper on the management of tubercular spondylitis, and Dr. J. Cheston Morris, of Philadelphia, reported an extraordinary case of prolonged gestation. Other papers by gentlemen who were not present were read by the secretary.

DR. R. S. SUTTON, the president of the Academy, in his address, deplored the existence of the great quantity of medical schools, and the low standard which they maintain. The character of the profession is continually lowered by the introduction of hordes of half-educated men. He advocated the requirement of a knowledge of the classics, as enlarging the vocabulary, training the memory and reason, cultivating the habit of close observation. The modern languages are essential to an advanced physician, and mathematics and mental and moral philosophy are elements in his outfit. The benefits of the physical sciences are obvious. The insufficiency of the usual professional equipment was pointed out, and greater strictness demanded of the medical schools. He believed that legislation only could remedy these evils. The teaching and licensing bodies should be separated, and the authority of the latter be derived from the State.

The following officers were elected for the ensuing year: Dr. L. P. Bush, Wilmington, Del., president; Drs. R. L. Sibbet, Carlisle, Pa., S. J. Jones, Chicago, P. S. Conner, Cincinnati, and V. P. Gibney, New York, vice-presidents; Dr. R. J. Dunglison, Philadelphia, secretary and treasurer. The next annual meeting will be held in September, 1887, in the city of Washington.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, NOVEMBER 4, 1886.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES, UPHAM & COMPANY,
283 WASHINGTON STREET, BOSTON, MASS.

AUTO-INTOXICATIONS.

IN a previous issue of the JOURNAL, we have referred to the experiments of Panum, Gautier, and others showing the development under certain conditions of alkaloids known as ptomaines and leucomaines, from decomposing animal structures and from certain fluids in the living animal, which alkaloids have a most intensely poisonous action when introduced into the animal economy. The practical bearing of these facts is obvious.

A further contribution to this subject, dealing more particularly with the clinical side of it, was made at the last International Medical Congress at Copenhagen, the official report of which has just been received. Professor R. Lépine, of Lyons, read the paper, in which he discussed two sources of possible auto-intoxication, the one by absorption from the digestive canal, the other from the secretions, particularly renal, in acute diseases. This two-fold source of infection had already been pointed out by Professor Bouchard. Among the cases cited by M. Lépine of probable absorption from the intestinal canal, is one in which a patient, operated upon by Professor Mollière for strangulated hernia, and having an artificial anus in the right inguinal region, developed after five months a sudden delirium with general scarlatiniform eruption, dilated pupils and rapid pulse. The interne diagnosticated the case as scarlatina but this diagnosis was rejected, as there was no elevation of internal temperature and no angina. Atropia poisoning was suspected, but careful inquiry excluded that possibility. It was finally considered to be a case of septic absorption from the intestine. It is worthy of note that atropia rather than muscarine (as in the observation of Gautier), was the drug whose action the intestinal poison simulated. This somewhat bold diagnosis was confirmed by M. Mollière at the autopsy, when the segment of the intestine below the artificial anus, namely, the ascending colon, was found to contain a quantity of stagnated matter, apparently originally a mucous secretion, which had become intensely fetid. Other similar cases are given where the intestinal contents had been long retained, giving rise to attacks of high pulse, with normal temperature, profuse sweating, polymorphic cutaneous eruption, etc. One of the patients, a physician, had complained previous to his septic attack of a fæcal taste in his mouth.

In the case of acute diseases, the evidence presented by M. Pinard is necessarily largely physiological. The ethereal extracts made from the urine of typhoid and pneumonia patients, containing only a small part of the alkaloid which more complicated chemical processes would have removed, were deprived of all those normal constituents that might have an effect in obscuring the action of the alkaloids. Special precautions were also taken against the introduction in connection with the chemical processes employed of any substance which could produce toxic effects. The total urine of twenty-four hours from a pneumonic patient yielded even to the crude process of agitation with ether, enough of an alkaloid to kill five frogs. In a case of pneumonia the urine taken just before the crisis of the disease gave toxic alkaloids which could not be obtained two days later, after the defervescence had been established. The frogs which were killed by the injection of the alkaloid from a pneumonic patient, had acceleration of the heart action and that organ was found post-mortem in systole; while the frogs inoculated from typhoidal urine had slowing of the heart, which finally stopped in diastole. This might be taken in confirmation of the clinical observation that in pneumonia the pulse is more rapid proportionally to the temperature than in typhoid; but unfortunately there seems to be some doubt as to whether the dose of the alkaloid administered from the two kinds of urine was the same.

The conclusions reached provisionally by M. Lépine are:

(1) That the extract from two hundred cc. of febrile urine, deprived almost wholly of salts, are capable, if injected into a small mammal, of causing death in a few hours, which effect will not be produced by the extract from the same quantity of normal urine.

(2) There is no correlation between the toxic power of the extract (deprived of salts) from a given quantity of urine and the proportion of urea which that urine contains. In other words, the toxic organic matters are not proportionate to the urea. Anæmic patients, having a diminution in the excretion of urea, were found to have urine that was particularly toxic.

(3) There is a certain correlation between the toxic power of the alkaloids contained in the urine and that of the urinary extract deprived of salts. Thus, in the pneumonia patient, the urine, before defervescence, contained a toxic alkaloid and also gave a very poisonous extract, while, two days later, the crisis having passed, there was no alkaloid discoverable, and the extract was much less poisonous. Yet the density of the two urines was the same.

(4) There is sometimes a correlation between the gravity of the disease and the toxic power of the urinary extract, but this correlation is by no means constant.

(5) Finally, it seems clear to the author that certain urines contain poisonous organic principles which may be supposed to have an influence upon the morbid phenomena of the diseases which they accompany; this view is confirmed by the facts observed as to auto-infection from the intestinal canal.

In the discussion which followed this paper, Dr. Stadelmann, of Königsburg, spoke of the evidence of auto-infection in certain forms of diabetes mellitus, leading to diabetic coma, which, in its complex of symptoms, corresponded closely with the complex of symptoms induced in the herbivora by poisoning with acid injections. The formation of acid and its elimination through the urine was found by Stadelmann to be much greater than normal during diabetic coma, and he ascribed the symptoms to the seizure of the acid upon the fixed alkalies of the blood. Hence follows, according to him, the indication for treatment in diabetic coma, namely, the intravenous injection of alkalies (carbonate of soda).

Professor Edelson, of Kiel, spoke of the evidence of auto-infection from the intestinal canal, and referred to the experiments of Panum in which the injection into animals of toxic alkaloids from the bowels had induced the symptoms of excessive drowsiness, which symptoms he had himself noticed clinically in cases of obstipation. He therefore believed that one of these alkaloids had poisonous properties resembling those of morphine.

HYPNOTISM AS A PHASE OF THE MIND-CURE.

IT cannot be as yet claimed that hypnotism has won for itself a definite and well-recognized place in the domain of therapeutics, or that it is always possible to separate the fraudulent from the genuine in the performances of the professional adept. The phenomena of so-called "mesmerism" and "animal magnetism" have too long been the *jeu d' esprit* of the unscrupulous charlatan, and there is connected therewith too great an accretion of the apocryphal, to seriously attract the attention of many physicians who are mainly solicitous for positive methods in theory and practice. In fact, the reality of the phenomena has been repeatedly called in question by critics who, however, may have pronounced judgment from too limited a stand-point of observation.

However this may be, it is certain that among some continental physicians hypnotism is attracting increased attention as a remedial agent, and not only the reality of the phenomena, but the marked benefit sometimes derivable from the new system of *psychotherapy* (so-called by its advocates) have been recognized by such different men as Chemnitz and Weinhold, Ruhlmann and Opitz, Heidenhain, Grutzner, Berger, Preyer, Fischer and Wiebe, and Czermak, of Germany; Lombroso and Giovanni in Italy; Charcot, Auguste Voisin, Charles Richet, Liebeault, Bernheim, the late Professor Lasègue, Pitres, Beaunis, Bottey, Prospère Despine and others, in France.

The literature of hypnotism is now quite extensive; besides numerous review and magazine articles, several quite portly volumes have appeared within the last five years, the most important of which is the work of Professor Bernheim, of Nancy, entitled: "De la Suggestion et de ses Applications à la Thérapeutique," and published the present year by O. Doin.

As for the meaning and scope of hypnotism, the scientific men who now stand as its representatives do not claim that there is anything in the phenomena which they have observed, which is contrary to the physiological and psychological conceptions which science has established in our time. Bernheim, who scouts the pretensions of those who would make of hypnotism a prop of spiritism, declares that "of marvels such as 'second sight,' prevision of the future, 'mind reading,' vision at a distance or through opaque objects, transposition of the senses, clairvoyant insight into physical states and remedial indications, I have seen nothing and know nothing." Equally do they scout the idea that "the phenomena determined in the hypnotic state are due to a magnetic fluid, or some sort of emanation going from one organism to another." This was the old view, which was effectually exploded by Braid in 1841, who taught that the hypnotic condition and the phenomena associated therewith, are purely of a subjective order, being dependent on the nervous states of the subject himself. What most strikes an ordinary observer is the automatism of the hypnotized subject who is for the time (to use Dr. Carpenter's simile) a mere puppet, moved by leading strings in the hands of the operator. It is by *suggestion* that the latter manipulates his subject, and this is now the favorite word to designate the phenomena in question. The hypnotized individual illustrates then only the ordinary laws of the nervous system; with the cerebral voluntary activity and consciousness dormant, he is much in the condition of the decapitated frog, says Prospère Despine.

As for the number of persons in any community amenable to the hypnotic influence, the proportion, according to the statistics of Liebeault, is about fifteen per cent. Bernheim finds the proportion much larger. "I have been able by my researches to assure myself," he says, "that refractory subjects constitute the great minority." It is interesting in this connection to note that Bernheim finds the best subjects to be those who have all their life long been accustomed to implicit obedience to their superiors, such as soldiers, day laborers, and nuns. Yung adds that hysterical persons are most susceptible to the "magnetic influence."

Hypnotism is a state in which the subject is completely under the control of the person who has induced the somnambulism. It might be inferred then that this power might be abused for criminal pur-

poses by unscrupulous experts. Bernheim, however, who has devoted a chapter to this subject, has been able to find only one or two well attested cases of the kind. On the other hand, we occasionally read pleasing reports in foreign journals of this singular power being turned to praiseworthy ethical account, the hypnotizer "suggesting" to his patient who it may be, is lewd, ideas of chastity, to the untruthful, ideas of truth, to the selfish, ideas of altruism, etc.[1]

But it is as a remedial agent for the cure of physical disease that hypnotism as such, need be especially deserving of the attention of physicians, and if the new psychotherapy be what it is claimed to be by certain continental authorities, it might prove an acquisition to the resources of the practitioner. The professional hypnotizer claims largely to control the sensorial states of his patient as well as the cerebral springs of motion, and he tells the man suffering from lumbago, pleurodynia, migraine, etc.: "Your pain is all gone." If we may trust our authorities, above quoted, that assurance often proves to be the actual truth, the dynamic states which caused the painful sensation disappearing under the powerful stimulus imparted by the medical hypnotizer. Is the patient suffering from paralysis of a certain kind? the suggestion that he can move his arm or his leg will often arouse to activity the dormant nervous motor mechanism.

The following, among other cases reported by Bernheim, were benefited in a marked manner by hypnotism:

(1) Post hemiplegic bilateral trembling, with hemianæsthesia and contractures of the left extremities, due to central softening; these symptoms, which were proved by the autopsy to be dynamic, that is, the effect of a reflex cerebral irritation, and not of descending degeneration, were alleviated and kept in abeyance by hypnotic "suggestion."

(2) Hysterical hemianæsthesia; complete return of sensibility after one hypnotic séance.

(3) Hysteriform crisis with hysterical somnambulism. Rapid cure from hypnotism.

(4) Hysteria. Incomplete paraplegia, with anæsthesia of the legs. Restoration of the sensibility in one séance, of the motility in six séances.

(5) Hysterical aphonia, of two months' duration, cure by hypnotic suggestion.

(6) Nervous aphonia, lasting a month: cured by "simple affirmation."

(7) Gastric troubles of a nervous character. Anæsthesia of the limbs. Rapid disappearance of the anæsthesia by "suggestion." Temporary amelioration of the gastric troubles.

(8) Symptoms of multilocular sclerosis; notable amelioration and arrest for six months of the affection by hypnotism.

(9) Diffuse rheumatic myelitis. Marked amelioration by repeated "suggestion."

(10) Rheumatic and nervous "girdling" pains, and pains in the lower extremities for twenty months, making it impossible for the patient to walk. Cure by hypnotic "suggestion."

(11) Neuropathic insomnia, want of appetite, trembling, melancholy; cure by "suggestion."

(12) Partial chorea (confined to one arm); cure by hypnotism.

(13) Choreic movements of the hands, difficulty in writing; cured by "suggestion."

(14) Writers' cramp; cured by hypnotism.

(15) Nocturnal incontinence of urine; cured by hypnotism.

(16) Hysterical paraplegia; cured by hypnotism.

(17) Epigastralgia; cured by one séance.

(18) Intercostal neuralgia; cured by "suggestion."

(19) Rheumatic paralysis of the forearm and hand. Restoration under hypnotism.

(20) Old rheumatic arthritis of shoulder. Marked amelioration under hypnotism.

(21) Muscular rheumatism with cramps; cured by hypnotism.

(22) Rheumatic ileo-lumbar neuralgia; cured by hypnotism.

(23) Arthralgia consecutive to arthritis; cured by hypnotism.

(24) Pleurodynia; cured by "suggestion."

(25) Chronic articular rheumatism (of ankles); cured by hypnotism.

In summing up and classifying the different cases, Bernheim finds that of those treated by hypnotism and deriving benefit from it, 7 were suffering from organic affections of the nervous system, 9 were cases of pure hysteria, 12 were neuropathic, 11 were neuroses, (chorea, hemichorea, writers' cramp, etc.), 3 were cases of "paresis and dynamic paralysis," 4 were gastro-intestinal affections, 11 were classified as "divers pains," and 14 were rheumatic affections.

As to the question whether hypnotism is dangerous to those on whom it is practised, Bernheim replies, *no, if properly managed.* It disturbs none of the functions of organic life, and its effects on the cerebral innervation (especially in disordered states) are calmative. As a remedy against insomnia, it is almost unrivalled. It is worthy of note that Yung[2] and Barthe[3] take a different view, regarding hypnotism, whether induced by a second person, or *self-induced* (trance-mediumship, clairvoyance), as more or less hurtful to the nervous system of the subjects, enfeebling the control of the will, and fostering a credulous, spiritless and superstitious habit of mind. Hypnotism exalts the automatic at the expense of the rational and voluntary powers.

With regard to the alleged triumphs of "suggestion" in the department of healing, it should be mentioned that similar results have been placed on record by Charles Richet, Liebeault, Paul Richer and others in Paris, by Creutzfeld, Berger and Fischer, in Germany, and he would be a hardy man who would hastily gainsay such an accumulating mass of testimony.

Not the least interesting portion of M. Bernheim's book to which we have referred, is the chapter in which he correlates hypnotic therapeutics with mind or faith cure, and the miracles of healing performed in all ages, and attempts to show that all come under the same general law, and are susceptible of a similar explanation. As Braid overthrew the transcendental pretensions of the mesmerizers by substituting for their occult forces, forces that could be brought under scientific cognizance and control, so the progress of physiological inquiry has made plain the essential unity of the phenomena of *induced* and those of *natural* somnambulism, while certain morbid states, as hysterical catalepsy and coma, find their counterpart in occasional conditions of the hypnotized subject. It is, moreover, no longer doubtful that if the "faith healer," or modern "Christian scientist" has now and then, in some deluded but devoted subject,

[1] See the report of Henrot and Voisin at the recent meeting of the French Association for the Advancement of Sciences. Voisin's patient was a female, "debauched, coarse and lazy." During the mesmeric sleep (which he kept up for ten or twelve hours a day), he improved the opportunity to suggest to the patient ideas of obedience, of submission, of decency, and he exhorted her to useful labor. "A complete transformation was effected in several months!"

[2] Du Sommeil Normal, et du Sommeil Pathologique, Paris, 1884.

[3] Le Sommeil Non-Naturel, Paris, 1886.

awakened dormant powers into activity, it is by a mechanism precisely like that which our French psycho-therapists call "suggestion in the waking state."

DEATH BY A DRUGGIST'S ERROR.

THE fatal mistake of a Haverhill druggist, whereby eighty-eight grains of podophyllin were put up for one dose for a young woman, the sign *ss*, representing half a grain, being mistaken for eighty-eight, the mistake resulting in the death of the young woman, illustrates the folly of allowing young clerks with no preliminary study or preparation to undertake the responsibility of dispensing drugs.

Were the law whereby apothecaries are authorized to dispense medicines as stringent as it ought to be, or were there, in fact, any State Statute whereby a man with no fitness for the place is forbidden to sell powerful drugs (and in all foreign countries such protection is given the public, ignorant and incompetent men being excluded from the druggist's office), such mistakes would seldom or never occur. A very superficial knowledge of materia medica would have indicated to the dispensing apothecary that eighty-eight grains of podophyllin was a dose that it would be impossible for a physician to prescribe.

MEDICAL NOTES.

— The following application for a pension is copied from the records of a United States pension bureau in a Western city. Readers will kindly excuse its early English for the sake of its anatomical curiosities, and the light it throws upon the temptations to which examiners for pensions are subjected.

I do her by swar before god that i was shot betwixt my leggs and mi rite legg an in my hed; it went in to me rite in the middle an ripped me all to thunder, it cut of one of my strings and dropped one of my kasters in the bottom of the sak an there hit as been ever since, and mi wife says it is a dam shame, case it is sorter nocked me up on the family biz. but hant a mindin that air much; hits the bustin the damed ball done me behind, as i hats (hates) for it kom out rite in the cheek of mi as an left a big skar an it hurts when I set down that is what i want a pension for it is; I hant no dimikrat, nor i want shot in the as like some of these pizen dimikrats bout these parts say i was; i gott that facing the rebs i did an i was treated by a temprey hospital surgen named tod in a temprey hospital on the bank of tenese river in temprey camp; camp by the border of chatanoga tense; now ginthemens i want a pension, and if you dont give me one i'l be g–d d–m if i vote for any of your crowd agin;

fraterally yours til deth, B.

BOSTON.

— Dr. J. S. F. Bush met with a serious accident last week. He was thrown from his carriage, his horse running away, and one knee-joint was laid open, the patella being almost torn off.

— Dr. James R. Chadwick, who was delegated to represent Harvard University at the recent festivities at Heidelberg, tells a story of the "republican austerity" which he was supposed to illustrate. For while other delegates presented their credentials emblazoned upon parchment, and enclosed in cases of velvet and gilt, all that he had to offer was an informal note, written on a half-sheet of paper by President Eliot, and bearing date at his summer residence at Mt. Desert. — *Harper's Weekly.*

Dr. Chadwick's credentials, we believe, were mailed at Mount Desert, but bore date at Cambridge.

NEW YORK.

— The tenth annual commencement of the Training School for Nurses of the Charity and Maternity Hospitals, on Blackwell's Island, took place on the 26th of October, in the chapel of Charity Hospital. Dr. Henry Goldthwaite presented diplomas to a graduating class of twenty-four, and Commissioner Brennan gave each member of the class a nurse's pocket-case.

— A somewhat sudden and serious outbreak of small-pox, the origin of which has not yet been traced by the authorities, has occurred in Brooklyn, and Health Commissioner Otterson has appointed six sanitary inspectors on special vaccination service. An extra force of men has also been assigned to duty on the fumigating corps.

— Measles has become quite prevalent in New York. During the week ending October 30, there were reported 162 cases. During that ending October 9, the number was 55; October 16, 95; and October 23, 108. 420 cases have been reported during the past four weeks, but the mortality has been low, only 37 deaths having occurred from the disease. Most of the cases have been in charitable institutions.

Miscellany.

GREAT WITS AND MADNESS.

THE JOURNAL has already, in a previous volume, referred to the marked strain of madness in the family of Victor Hugo, who had, on the maternal side, a mad uncle and mad cousins, whose brother Eugene died in a mad-house, and whose only surviving daughter, Adele, has been for years in confinement. A Paris letter says: "A controversy is now going on in the scientific world on the conditions under which genius is produced. Senator Naquet, and Drs. Marechal, Jacopy, and Bull say that it is a neurosis, and that most great men have had mad or epileptic ancestors or descendants, or been themselves attacked with epilepsy, or been, in some respects, on the very brink of lunacy. Cæsar and Peter the Great had falling sickness. Napoleon was subject to long fits of fainting that resembled catalepsy. Newton had also a disordered nervous system. Byron's mother was a raging, irresponsible termagant, and father no better. Isabella the Catholic, who was certainly a woman of genius, had a mad uncle, a mad brother, and mad daughter, the ancestor of all the Spanish and Austrian Hapsburgs. Her (Isabella's) grandson, Charles V, also a man of prodigious politi-

cal genius, was epileptic, and the progenitor of a line which ended in idiocy. Pascal had fits and hallucinations. Luther also had the latter, and thought he saw the devil in person coming to tempt him. William the Conqueror was the son of Robert the Devil, who must have had, to judge from the legend which has been handed down, a nervous system that ran riot. According to the new theory, genius, like the orchard pear or apple tree, or the double rose, or dahlia, is abnormal, and except in an intellectual sense, sterile. Thus Dante (a hypochondriac), Michael Angelo, Raphael, Shakespeare, Cowper, Wordsworth, Byron, Scott, and De Quincy either left no posterity, or families that soon died out. That of Victor Hugo is not apparently destined to live long."

SIR SPENCER WELLS ON THE OCCUPATIONS OF WOMEN AND OVER-PRESSURE.

In his inaugural address before the Sanitary Congress, recently held at York, England, Sir Spencer Wells spoke on the above subject as follows, according to the report in the *Lancet*. "So far as concerns the mental and physical training of children, and giving women the option of other occupations than those of domestic life, I see no great cause for alarm. It is an age in which education — at any rate for the middle classes — must be pushed far beyond the limits which our fathers thought wide enough for us. Mere rule-of-thumb work is almost out of date, and there are so many industries in which scientific knowledge and exactness are requisite, that the want of early education cuts off a young man's chances of advancement. To engage in most of the recent applications of steam power, electricity, magnetism, and chemistry — to be available in carrying out the complexities of engineering science — a workman must be something more than a mere machine. He must have head as well as hands — brain as well as muscle; and as uneducated brains are not worth more in the labor market than untrained muscle, we must be content to make some sacrifice in the culture. While we pity the few who fall in the struggle, we must remember that there is no chance for those who stand still. As for the outcry about the dangers from women taking up men's work, it is breath wasted. A great many failures will outweigh a few successes and bring the balance right. For my own part, I think women capable of a great deal more than they have been accustomed to do in times past. "To suckle fools and chronicle small beer" surely cannot be the chief end of woman. If overwork sometimes leads to disease, it is more morally wholesome to work into it than to lounge into it. And if some medical practitioners have occasionally observed cases where mental overstrain has led to disease of mind or body, I cannot deny that I also have at long intervals seen some such cases. But for every such example I feel quite sure that I have seen at least twenty where evils equally to be deplored are caused in young women by want of mental occupation, by deficient exercise, too luxurious living, and too much amusement or excitement. Again, we have heard much of late about over-pressure from work in schools. This is one of the novelties of our time. No doubt it exists, and I think it may in part be traced to some of our sanitary success. We have reduced the mortality of early infancy. Many children who would formerly have died off-hand are now saved, and find their way into the schools. They are the survivals of the least fitted. They live, but they are not strong — not so strong as the average. They have to submit to the same routine, and to be forced up, if possible, to the same standard as the rest. But the effort is too much for them. Their frames are not hardy enough to resist the mental strain. They show all sorts of nerve symptoms, disappoint the teachers, and are the types brought forward as victims of the system. The vice of the system is that it is indiscriminate. There is no revision of the recruits, and the tasks are not apportioned to the feeble powers of sanitary survivors. This is an evil which will remedy itself in time by the growing up of a larger proportion of strong children, and the present difficulty may be got over by a little patience and moderation — a little more regard to sanitary logic. The children must have training before education, and must be put upon something even less than a half-time system."

RESOLUTIONS IN MEMORY OF ALLEY TALBOT WAKEFIELD, M.D.

At a meeting of the Cambridge Medical Improvement Society held October 25th, 1886, the following resolutions were passed:

Whereas, In the death of Dr. Alley Talbot Wakefield, on the 18th inst., this society has lost a much esteemed member, we wish to express our sense of loss, our appreciation of his character and ability, and our sympathy with his family and immediate friends.

During his brief association with us we recognize a character pure, noble, and of strict integrity. We found him devoted to his work, prompt and efficient in emergencies because of his thorough knowledge and perfect self-control.

To exceptionally good natural endowments he had added unusual advantages in study and hospital practice, and the success he had already achieved gave assurance of a bright professional career in the future.

Frederic W. Taylor, M.D., *Secretary*.

Correspondence.

THE GIFT OF MRS. WOERISHOFFER TO THE NEW YORK ACADEMY OF MEDICINE.

The following correspondence will explain itself:

New York, October 15th, 1886.

Dr. Everett Herrick, *Chairman Board of Trustees, New York Academy of Medicine*.

Sir,— In presenting a munificent donation to the New York Academy of Medicine, Mrs. Anna Woerishoffer was guided, first, by the great respect her late husband, Mr. Charles F. Woerishoffer always felt and expressed for medical science, and the medical profession, and second, by her conviction that it is better to aid and sustain such institutions of either science or charity as have already proved their faculty and right to exist by duration, results, and accumulated property, than to create new institutions.

After mature deliberation she came to the conclusion that the New York Academy of Medicine has, by its publications in the journals of the country, and in numerous volumes of transactions and bulletins, and by its regular stated and section meetings, contributed largely to the progress of medical science, and deserves eminently the name of a scientific body.

That after having existed forty years, collected an ever-increasing library, and accumulated considerable property, the New York Academy of Medicine holds out the promise of *perpetuity*.

That, by excluding politics and ethical strifes from its constitution and gatherings, it deserves the name of a

purely and exclusively scientific body, and thereby the confidence of the public; as it must necessarily become and be the centre of the scientific interests and labors of the medical profession of New York.

Mrs. Woerishoffer was also struck with the fact that the present building of the New York Academy is too small for its present and future purposes, that not only do its sections require more accommodations, but that every medical and scientific society of the city ought to find ample room within its walls and look upon the Academy as its proper centre; and finally, that the increasing library is in urgent need of a fire-proof building.

From these points of view, Mrs. Woerishoffer desires to contribute to the means required for enabling the New York Academy of Medicine to accomplish its great ends and reach its high aims, which she takes to be both truly scientific and truly humane.

I have the honor, Mr. Chairman, of enclosing Mrs. Woerishoffer's letter and her check for twenty-five thousand dollars. Very respectfully yours,

A. JACOBI, M.D., *President.*

NEW YORK, October 13, 1886.

DR. A. JACOBI:

Dear Sir,— Please find enclosed a check for the "Academy of Medicine," which I send you in memory of my husband, the late C. F. Woerishoffer. In selecting the Academy of Medicine as one of the institutions to which I intend to distribute a certain sum in accordance with the wishes of my husband, I am led by the high appreciation Mr. Woerishoffer always entertained for the medical profession. Yours very sincerely,

ANNA WOERISHOFFER.

NEW YORK, October 22, 1886.

MRS. ANNA WOERISHOFFER, New York.

Dear Madam:—At a meeting of the Academy held Thursday evening, October 21st, 1886, the following resolutions, moved by Fordyce Barker, M.D., and seconded by C. R. Agnew, M.D., were unanimously adopted.

Resolved, That the New York Academy of Medicine accept with the warmest thanks and gratitude, the noble gift of twenty-five thousand dollars from Mrs. Anna Woerishoffer, as an expression of the appreciation by her late husband, Mr. Charles F. Woerishoffer and herself, of the importance of the Medical Profession to the health and welfare of the public, as well as to individuals, and the necessity for the development of its highest culture.

Resolved, That the names of Mr. and Mrs. Charles F. Woerishoffer, be inscribed in the Academy for permanent record as Benefactors.

Resolved, That a copy of these resolutions, duly engrossed, and signed by the President, Recording Secretary and Treasurer, be transmitted to Mrs. Woerishoffer.

A. JACOBI, M.D., President.
A. M. JACOBUS, M.D. Recording Sec'y.
F. A. CASTLE, M.D., Treasurer.

COCAINE ADDICTION.

MR. EDITOR,— If any reader of your JOURNAL has met with a case of cocaine addiction and will send me the fullest details at his command, I'll thank him for the courtesy, reimburse him for any expense incurred, and give him full credit in a coming paper. J. B. MATTISON, M.D.

BROOKLYN, 314 State St.

REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 16, 1886.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,235: under five years of age 887; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 505, consumption 230, lung diseases 192, diphtheria and croup 169, diarrhœal diseases 138, typhoid fever 64, malaria fever 57, whooping-cough 22, measles 19, scarlet fever 13, erysipelas 10, cerebro-spinal meningitis eight, puerperal fever four, small-pox (Brooklyn) one. From malarial fevers, New Orleans 17, New York 11, Baltimore 10, Brooklyn seven, District of Columbia six, Philadelphia and Charleston three each. From whooping-cough, New York nine, Brooklyn and Baltimore three each, Nashville two, Philadelphia, Cincinnati, District of Columbia, Pittsburgh and Lawrence one each. From measles, New York eight, Pittsburgh five, Brooklyn, Boston and Charleston two each. From scarlet fever, New York and Cincinnati four each, Philadelphia three, Pittsburgh and Springfield one each. From erysipelas, District of Columbia four, New York, Brooklyn, Boston, Cincinnati, New Orleans and Pittsburgh one each. From puerperal fever, New Orleans two, Boston and District of Columbia one each.

In the 23 cities and greater towns of Massachusetts with a population of 1,048,322 (population of the State 1,941,465), the total death-rate for the week was 17.41 against 20.28 and 20.21 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,093,817 for the week ending October 2d, the death-rate was 20.6. Deaths reported 3,592: infants under one year of age 1,206; acute diseases of the respiratory organs (London), 187; diarrhœal diseases 532, scarlet fever 61, fever 59, diphtheria 33, measles 32.

The death-rates ranged from 15.2 in Brighton to 29.2 in Manchester; Birkenhead 21.3; Birmingham 21.5; Hull 24.3; Leeds 27.7; Leicester 22.0; Liverpool 26.4; London 17.0; Nottingham 21.6; Sheffield 23.2; Wolverhampton 27.4.

In Edinburgh 14.8; Glasgow 21.8; Dublin 22.8.

For the week ending October 2d, in the Swiss towns, there were 45 from diarrhœal diseases, consumpton 23, lung diseases 10, diphtheria and croup four, typhoid fever two.

The death-rates were: at Zurich 1.9; Geneva 15.1; Basle 25.2; Berne 21.4.

REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 23, 1886.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,272: under five years of age 905: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 377, consumption 286, lung diseases 208, diphtheria and croup 187, typhoid fever 55, diarrhœal diseases 41, whooping-cough 22, malarial fevers 22, scarlet fever 18, measles 14, cerebro-spinal meningitis seven, erysipelas five, puerperal fever four. From malarial fevers, New York 10, Brooklyn nine, District of Columbia two. From whooping-cough, Brooklyn nine, New York four, Philadelphia and Pittsburgh three each, Chicago, District of Columbia and Lowell one each. From scarlet fever, Philadelphia, Chicago and Cincinnati four each, New York and Pittsburgh, three each. From measles, New York nine, Pittsburgh three, Brooklyn and Nashville one each. From cerebro-spinal meningitis, New York and District of Columbia two each, Cincinnati, Worcester and Springfield one each. From erysipelas, Chicago two, New York, Brooklyn and Pittsburgh one each. From puerperal fever, New York, Chicago, Boston and District of Columbia one each.

In the 20 cities and greater towns of Massachusetts, with a population of 1,012,143 (population of the State 1,941,465), the total death-rate for the week was 20.23 against 17.41 and 20.28 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,093,817, for the week ending October 9th the death-rate was 19.3. Deaths reported 3,369: infants under one year of age 999; acute diseases of the respiratory organs (London) —, diarrhœa 324, scarlet fever 70, fever 70, measles 42, diphtheria 42, whooping-cough 30.

The death-rates ranged from 14.2 in Bristol to 29.9 in Preston; Birkenhead 22.9; Birmingham 17.5; Bradford 18.3; Hull 20.7; Leeds 21.9; Liverpool 25.4; London 17.2; Manchester 23.1; Newcastle-on-Tyne 23.9; Sunderland 21.7.

In Edinburgh 19.9; Glasgow 23.9; Dublin 23.1.

For the week ending October 9th, in the Swiss towns, there were 30 deaths from consumption, diarrhœal diseases, 29, lung diseases 13, typhoid fever five, whooping-cough one, diphtheria and croup one.

The death-rates were: at Zurich 7.6; Geneva 13.1; Basle 13.3; Berne 17.1.

The meteorological record for two weeks ending October 23, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps: —

Week ending Saturday, Oct. 16, 1886.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 23, 1886, TO OCTOBER 29, 1886.

WEBSTER, WARREN, major and surgeon. Leave of absence on account of sickness further extended one year on account of sickness. S. O. 244, A. G. O., October 20, 1886.

BILLINGS, J. S., major and surgeon. Granted leave of absence for eight days. S. G. 246, A. G. O., October 22, 1886.

LANDERDALE, JOHN V., captain and assistant surgeon. Leave of absence extended one month. S. O. 249, A. G. O., October 26, 1886.

CARSON, Jos. K., captain and assistant surgeon. Granted leave of absence for one month, to take effect when his services can be spared. S. O. 246, A. G. O., October 22, 1886.

MOSELEY, E. B., captain and assistant surgeon. Relieved from duty in Department of the Columbia and ordered to report in person at headquarters, Division of the Pacific, for assignment to duty. S. O. 87, Division of the Pacific, October 16, 1886.

TAYLOR, B. D., captain and assistant surgeon. From Department East to Columbus Barracks, Ohio.

TESSON, L. S., captain and assistant surgeon. From Department Texas to Department East.

BARROWS, C C, first lieutenant and assistant surgeon. From Department of Arizona to Department East.

EGAN, P. R., first lieutenant and assistant surgeon. From Department of Arizona to Department of Texas.

WALKER, F. V., first lieutenant and assistant surgeon. From Department East to department of Texas. S. O. 244, A. G. O., October 20, 1886.

CARTER, E. C., first lieutenant and assistant surgeon. Granted leave of absence for six months, with permission to apply for an extension and to go beyond sea, to take effect when his services can be spared. S. O. 244, A. G. O., October 20, 1886.

BLACK, CHARLES S., first lieutenant and assistant surgeon. Granted leave of absence for two months on surgeon's certificate of disability, to take effect when his services can be spared. S. O. 244, A. G. O., October 20, 1886.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING OCTOBER 30, 1886.

DIEHL, OLIVER, passed assistant surgeon. Granted three months leave from 26th inst.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDING OCTOBER 23, 1886.

URQUHART, F. M., passed assistant surgeon. Relieved from duty at Cape Charles Quarantine, to proceed to Washington, D.C., with Steamer "Woodworth," October 20, 1886.

WASDIN, EUGENE, passed assistant surgeon. Promoted and appointed passed assistant surgeon, from October 1, 1886, October 20, 1886.

WILLIAMS, L. L., assistant surgeon. Granted leave of absence for three days, October 16, 1886.

SOCIETY NOTICES.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT. — THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE will meet at 19 Boylston Place, on Wednesday, November 10, at 7.45 o'clock. Papers: Dr. P. C. Knapp, "An Unusual Form of Professional Neurosis." Dr. H. C. Haven, "A Plea for the more careful Consideration of the Importance of the Methods and Manner of Infant Feeding." Dr. F. C. Shattuck, "A Case of Malignant Endocarditis." Dr. E. W. Cushing, "Fatal Perforation of the Appendix Cœci, with Specimen."

ALBERT N. BLODGETT, M.D., *Secretary.*

F. I. KNIGHT, M.D., *Chairman.*

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The next meeting of the Society will be held at the Medical Library Room, No. 19 Boylston Place, on November 11th, at four o'clock, P.M. Papers: Dr. W. Thornton Parker's paper postponed from last meeting, entitled "The Removal of a Large Vaginal Tumor." Dr. E. W. Cushing, "The Use of Irrigation in Gynæcology." Dr. Cushing will also show with the microscope specimens of the *gonococcus*.

H. J. HARRIMAN, *Secretary.*

Original Articles.

THREE CASES OF SUPPURATING OVARIAN TUMOR TREATED BY DRAINAGE.[1]

BY J. W. ELLIOT, M.D.

THESE cases seem naturally to divide themselves from other abdominal operations, I therefore report them separately.

CASE I.— CYST DISCHARGING INTO RECTUM: DRAINAGE PER RECTUM. CURED.

Miss C. was a servant, twenty-seven years old. I first saw her on October 27th, 1882. She was thin and in miserable health. She complained especially of bearing-down pains and of a constant discharge of pus from the rectum. Five years previous she had experienced great relief from a sudden discharge of pus from the rectum. From that time she had very little trouble until two years before I saw her, when the discharge began again. She suffered from constant pain in the lower abdomen and had frequent attacks of vomiting. She was very constipated and every movement caused severe pain.

On examination I found a tumor the size of a large orange in the right side of the pelvis, the uterus being pushed to the left. The uterus and tumor were evidently bound together by adhesions, but the whole mass was movable in the pelvis. I considered the case one of suppurating cyst or fallopian tube discharging into the rectum, and advised her to enter the Free Hospital for Women, which she did.

November 23d. Under ether I succeeded in finding the opening into the cyst, which was very high up in the rectum. I was able to bring this opening into view by putting a Sims's speculum into the rectum (patient in Sims's position) and pulling down the anterior wall with double hooks and tenaculum. This opening being dilated and enlarged, several ounces of pus were evacuated. A drainage-tube was put in and the cyst washed out. This operation caused only slight constitutional disturbance. The cavity was washed out regularly; the discharge diminished to a certain extent and the tumor became smaller, but the soft rubber drainage-tube gave us trouble by getting bent and clogged, and finally it was removed in about ten days because it caused severe pain of the anus. After waiting some weeks to see if the cavity was disposed to close, it became evident that the tumor still contained pus and required further attention.

January 18th. Ether was again given. The opening being dilated as before, numerous partitions inside the cavity were broken down with the finger. In this way the contents was thoroughly evacuated. Drs. Baker and Davenport were present and kindly assisted me. I then placed a hard-rubber tube, curved like a male catheter, which I had had made especially for this case, to obviate the difficulties caused by the soft rubber tube after the previous operation. The temperature rose to 104.2° F., but soon subsided. The cyst cavity could be thoroughly washed out with a catheter passed up inside the hard-rubber drainage-tube.

January 27th. The patient was doing well; the wash water returned clear, but there was severe pain.

January 30th. The abdomen was swollen and tender, the patient had a bad, hollow-eyed look, the temperature was raised and the pulse rapid. There was evidently a beginning peritonitis. The drainage-tube was removed and a poultice applied to the abdomen.

February 3d. The above symptoms were disappearing.

February 7th. Patient much better, eating well. From this time on there was a steady improvement, and on February 16th, she was up and about the ward.

March 4th. There was no discharge from the rectum. Patient in good condition.

March 8th. Patient discharged from the hospital cured.

I saw her again about a year later. She had gained forty pounds since the operation. The cyst, had entirely disappeared. The uterus was bound tightly to the sacrum from the contraction of the old cyst cavity. I afterwards freed the uterus from the sacrum, and when last seen in 1885, she was perfectly well.

CASE II.— CYST AND PERITONEUM INFLAMED, DRAINAGE THROUGH ABDOMINAL WALL: COUNTER OPENING IN VAGINA. CURED.

Miss D., nineteen years old, was sent to me by Dr. W. A. Dunn and was first seen at my office March 23d, 1885. Six months previous she had had difficulty in micturition: three months later she noticed swelling and pain in the lower abdomen. This had gradually increased. She had been seen by Dr. F. B. Harrington, who informs me that he found her with a temperature of 103° F., and put her to bed. After a month's rest in bed she was able to return to her work. But the pain and swelling soon became much worse. The menstruation had been natural until the last three months, during which time it had been very profuse, so much so that she had been much pulled down from the loss of blood. She was thin and very pale, and in wretched condition.

The outline of a fluctuating tumor was indistinctly felt just below the umbilicus. It had the indistinct feeling that an ovarian tumor might have if a blanket were placed between the tumor and the abdominal wall. The tumor was dull on percussion, while the flanks were tympanitic. The uterus was clearly felt in antiflexion, separate from the tumor but not freely movable.

The diagnosis was ovarian cyst, and she was advised to enter the Free Hospital. The operation was done on April 7th, 1885. On opening the abdomen I found the peritoneum from one-fourth to one-half an inch thick, very red and vascular, and studded with small gray granules. This peritoneum did not look in the least like anything I had ever seen, it was so red and vascular that it resembled liver or kidney tissue. When I opened it, it seemed as if I must have cut some strange organ. It bled profusely at every nick. In fact I should not have been in the least surprised had this patient died within six months of cancer of the peritoneum or tuberculosis. The cyst was finally reached and found to be very firmly adherent in every direction. Its removal was simply impossible. It contained two quarts or more of pus. The cyst was washed and sponged out and its walls stitched to the abdominal wall. A large opening was left through which two large drainage tubes were inserted. Dr. Whitney examined the fluid and reported that it was pus, but was probably from a cyst cavity.

There was very little disturbance from the opera-

[1] Read before the Boston Society for Medical Improvement, October 25, 1886.

tion. The temperature was never above 100° F. The cyst discharged freely and was washed out twice a day with carbolic 1-80. The patient was up and about in two weeks. She remained in the hospital until June 11th. The cyst was constantly washed out and the cavity contracted slowly. When she left the hospital the cavity was four inches deep and the tube three inches long. She had gained much flesh and strength. During the summer I saw her every two or three weeks and gradually shortened the tube. The discharge was much diminished. She appeared one day and stated that she had just been married.

July 30th. The cavity was three and one-half inches deep and barely large enough to admit a one-fourth inch drainage-tube. It discharged freely. Two hard tender lumps could be felt, one on each side of the fundus uteri.

In the fall the condition was much the same. The lumps above noticed were found to contain pus and were opened into the cavity. I washed the cavity with every known disinfectant and astringent, iodine, Heaton's hernia mixture, and finally with spirits of turpentine. All to no purpose, the cavity would not close.

February, 1886. She re-entered the hospital. A counter opening was made from the vagina into the bottom of the cavity and a large tube put through from the abdomen to the vulva. This caused very free suppuration which gradually subsided under constant washing. The tube was gradually shortened and the abdominal wound allowed to close. After the tube had been pulled down out of the abdominal opening it was at first found impossible to prevent it from slipping out through the vagina. It was, however, finally held in place by a silver wire passed up through the abdominal wound where it was fastened to a piece of wood and could be gradually led down by unwinding the wire.

In June she left the hospital with only a very shallow opening in the vaginal wall, all the tubes having been removed.

July 19th. I saw her at my office and found that all the lumps and hardness had disappeared from the abdomen. The openings had healed except that the old scar in the abdomen breaks down and discharges a little blood at each menstruation. She was perfectly well and keeping house.

CASE III.— CYST DISCHARGING PER VAGINA, DRAINAGE THROUGH ABDOMEN AND VAGINA: RELIEVED.

Mrs. W. was advised by Dr. Bush to apply to the Free Hospital. I first saw her at her home on April 23, 1885. She was an actress, aged twenty-eight. In September, eight months before I saw her, she had first noticed an enlargement of the abdomen. She then lived in a small Western town. Her doctor told her that she had a tumor. It grew larger very rapidly, and in November it was tapped, and thirty pounds of fluid drawn off. Six weeks later it was tapped again, and three gallons more fluid drawn off. At the same time, an attempt was made to open the tumor through the vagina, but no fluid was so discharged. After this operation she was sick in bed for three months. She was brought to Boston in March, since which time she had been very ill. Two weeks previous to my visit, the tumor broke and discharged through the vagina. Since then she had had a profuse greenish discharge. She suffered great pain, and had taken a grain and a half of morphia a day for several months. She had always been well before this illness, with the exception of two miscarriages eight years previous.

The patient was very small and thin, and in a deplorable general condition. She was feverish and discouraged. A large, tender, fluctuating tumor filled the whole abdomen, extending so high up that the ribs were lifted. The cyst was discharging pus through the vagina. The uterus was crowded up behind the pubes.

When she entered the hospital the pulse was 150, and very poor; the temperature was 103.5° F. There was occasional vomiting of food. At a consultation of the hospital staff, Dr. Baker, Dr. Davenport, and myself, it was decided that the tumor was a suppurating ovarian cyst, and that the patient was in a very critical condition, and would surely die unless something was done immediately.

On April 27th I operated, without much hope that she would recover. On opening the abdomen, I found the cyst universally adherent, and filled with stinking pus. This being evacuated, the hand was passed in, and a large mass of papillomatous growth scooped out. This caused much bleeding, and sponges were packed into the cyst. After the large cyst was emptied, a small tumor of the other ovary became apparent. An attempt was then being made to dissect out the sac of the cyst when the patient became collapsed, the pulse being almost imperceptible. A drainage-tube was then pushed through Douglas's fossa into the vagina, and the cyst wall was quickly stitched to the abdominal wall. One drainage-tube went through the cyst, and another was only in the abdominal opening. Dr. Green, Dr. Johnson, Dr. Clark, and the late Dr. Lombard assisted me.

The patient was put to bed with heaters. Stimulants were given by rectum and subcutaneously. She rallied in a few hours, and although the pulse was very weak for a few days, she was soon in much better condition than before the operation. The temperature fell to 99°, and stayed there for a time. The vomiting ceased, and the appetite improved. The cyst was washed out several times a day with an antiseptic solution. The discharge was profuse at first, but gradually diminished. She had an attack of bronchitis, and during a paroxysm of coughing, the vaginal tube, which had been cut from the abdominal tube, was forced out.

All went well then until the fourteenth day, when the temperature and pulse began to rise again; temperature 103.4° F., pulse 150. There was also great pain in the side.

March 15th. The patient was etherized, and on exploring the region where the pain was referred, it was discovered that one of the cyst-cavities had closed and formed an abscess. This was opened and drained.

Things looked better after this. She began to improve again, but on May 30th the pulse and temperature began to go up again, and it was impossible to keep the discharges from smelling.

June 2d. Under ether, an examination was made, and an abscess broken open inside the cyst. In searching for more pus-cavities, the cyst wall was accidentally opened, and the finger went into the peritoneal cavity. Fresh drainage-tubes were put into all the cavities, and one was passed again through Douglas's fossa into the vagina. After this operation there

was severe pain, requiring much morphia. The pulse continued rapid, and the patient was still in a critical condition.

June 4th. It was evident that an abscess was forming in the peritoneal cavity, around the hole made in the cyst wall at the last operation. There was great pain, some vomiting; almost all food was refused. Pulse 130, temperature 102.° The patient was very low.

June 15th. I etherized her again for the third time since the operation. The intra-peritoneal abscess was opened, and a large quantity of stinking pus evacuated. I then began a systematic search in all directions to find retained pus, and, to my dismay, I found a sponge at the bottom of one of the cavities. This sponge had been crowded in to stop the bleeding from the papillomatous growth, when the patient collapsed at the first operation, and had long since been forgotten. Everything was thoroughly disinfected, and all the tubes replaced. After a time some of the cavities closed, and the cyst was more easily drained. The large cyst-cavity gradually contracted. Finally, we made a desperate effort to break off the morphia, but failed, and I am sure that the patient would have died if we had continued to withhold it. She gradually gained strength until the end of June, when she was moved from the hospital. At home she continued to improve. All the tubes were removed, except the long one, which ran through the cyst.

July 28th. She was so much improved that she was up and about the room; was taking only one-quarter of a grain of morphia a day. The vaginal part of the tube was soon removed, and only a short tube remained in the abdominal opening. She went into the country for the summer, where she improved so much that when she walked into my office in October I did not recognize her. She had gained much flesh and strength. Since then she has been able to go about and enjoy life.

I saw her on October 21, 1886, when she told me that she had removed the tube a year ago, and that since that time the sinus would remain healed for several months at a time, but would suddenly break open and discharge pus for a few days, and then heal again. I found that the old tumor had disappeared, but that the small one on the other side had grown to the size of a cocoanut; I advised its removal.

It should be understood that the deplorable condition in which I first found the patient was due to the tapping which had been done several months previous. In spite of the outcry against tapping, we continue to meet patients suffering from that maltreatment.

Although we know from experience in ovariotomy that patients may tolerate an extraordinary amount of damage in the way of tearing out an adherent cyst wall, we also know that patients not infrequently die on the table, or soon after these most severe operations. Drainage offers a chance for some of the bad cases. I have taken pains to follow out these cases, in order to get a clear idea of the course and results of drainage. With this side of the picture complete, we shall be better prepared to decide in a given case whether to risk a very serious operation, or to go through with the tediousness of drainage. Schroeder and others have objected to drainage, on account of the tendency to recurrence. Rheinstaedter [2] reports seven cases where more or less of the cyst was left and drained; all seven recovered without recurrence. Certainly, there has been no special tendency to recurrence in my cases, and one was papillomatous, operated on one and a half years ago. If any of them recur in the future, I have, at least, the satisfaction of giving them a year or two of comfortable life. It may also be possible to do another operation, under conditions more favorable than the first.

These cases have raised the question of how ovarian cysts discharging into the various cavities are best treated. If the cyst is discharging into the rectum or vagina, an attemp should be made to drain in that direction, as in cases I and II. If the cyst is discharging into the intestine or bladder, it should be removed by laparotomy, and the opening into intestine or bladder closed by suture.

THE MALE URETHRA.[1]

SOME NEW AND PRACTICAL OBSERVATIONS ON ITS ANATOMY IN RELATION TO ENDOSCOPY, LITHOLOPAXY, AND CATHETERIZATION.

BY OTIS K. NEWELL, M.D.,
Assistant in Anatomy at the Harvard Medical School.

During the early part of the present year, it occurred to me, in observing a case of litholopaxy at the Massachusetts General Hospital, that there could be no reason why the same sized tubes which so readily enter the normal urethra could not be applied to advantage in an endoscopic examination of the bladder, urethra, and other parts. I trust that the results of my investigation in this connection will not fail to be of interest and value. Three years ago, at Professor Dittel's clinic in Vienna, I had occasion to make an endoscopic examination of the urethra, with the instrument there in vogue, and from what I was enabled to see through its small calibre, together with Professor Dittel's rather sceptical views in regard to its general utility, I gave but little further attention to the subject of endoscopy. Having had made a No. 30 tube, however, a more particular description of which will be given further on, I was much surprised and gratified to find with what readiness and satisfaction the surface of the bladder or urethra could be examined by means of light thrown in by the ordinary laryngoscopic mirror. My first examinations were made upon the cadaver, and there the mucous membrane could be plainly seen, and any small body, such as a piece of sponge, a tack or screw, when introduced into the bladder, readily found and recognized. That bodies of considerable size could be easily introduced through the 30-tube naturally led to thoughts of instrumentation within the bladder, and of this I will speak more fully later on. The first tube I had made was one corresponding in length to the ordinary catheter, cut off at the lower or visceral end obliquely, at an angle of about 45°, and closed with a thin plate of glass. This, I later learned, corresponded much with Grünfeld's straight, fenestrated endoscope, and was designed to prevent the entrance of urine into the tube, and admit of inspection by placing the glass against the bladder wall. The rather obscure picture through the glass, however, led me to soon abandon this for a similar open tube, into which a staff, or guide, was inserted for its better introduction.

[1] Read before the Suffolk District Medical Society, October 30, 1886.

Since the clearness of view through the tube depended upon the amount of light thrown in, and this was determined by the length of the endoscope, I next endeavored to ascertain how short an instrument could be, and still admit of ready introduction into the bladder. The examination of a large number of cases for this purpose has led to what has been, to me, an astonishing result, considering the previous knowledge of this subject, at least, in its application. I find, namely, that an instrument, catheter, sound, or evacuating tube, having a length of five inches or more, can be readily introduced through the urethra into the bladder of any normal subject, the requisite manipulation being but little more difficult than that required in the introduction of instruments having the traditional measurement.

The pendulous portion of the urethra, the part anterior to the triangular ligament, can be readily folded together, so that its long axis occupies not more than from one and a half to two inches. I have found no case where an endoscope six inches in length could not be introduced into the bladder, so as to have two inches or more protruding from the visceral orifice. To ascertain this, I have made careful measurements of fifteen adult urethræ in subjects from thirty to seventy years of age, besides examining quite a large number of unrecorded cases. The length of the posterior urethra, made up of the membranous and prostatic portions, varies but little, the prostatic portion averaging about one and one fourth inches, and the measurement of the membranous region three-quarters of an inch or less. An enlarged prostate seldom increases the length of this portion to any great degree, the growth being mostly lateral, and affecting more its calibre and direction, the middle lobe, when much enlarged, standing as an obstruction before the vesical orifice.

We have then, in the male subject, an urethra, the posterior portion of which averages two inches in length, and presents beyond this, as its continuation, a canal which, from its anatomical structure, and that of its surrounding parts, is readily folded together, so as to have the same length, the variation in different individuals, when the urethra is thus apposed, being of no considerable degree.

The applied anatomy of the male urethra, then, is such that we may consider the length of this canal to be, for surgical purposes, but four inches, increased, in cases of enormous hypertrophy, to a possible six. Better than to further attempt the demonstration of this fact, I will leave it to the more convincing investigation of those of you to whom it may be of interest, and consider at once its application to the subjects indicated in the title of my paper.

ENDOSCOPY.

After becoming interested in this subject, I carefully read the admirable and voluminous work of Professor Grünfeld, who, by adopting the simple laryngoscopic mirror as a light source, and making numerous improvements in the endoscopic instruments, together with the most patient and systematic labor, has accomplished more than any of the recent workers on this subject. To all who may be interested in it, his book will prove of great value. It is sufficient to mention here that to the endoscope we owe most of our exact knowledge of urethral pathology, and an idea of what patient work with this instrument in the hands of Bozzini, Désormeaux, Grünfeld, and others has accomplished, may be obtained by quoting from the index to the illustrated plates in Grünfeld's work: 43, Urethritis Simplex; 48, Urethritis Granulosa, with rigid walls; 55–58, Two Ulcers on the urethral mucous membrane of a man; 59, Urethral Chancre; 61, Primary lesion of syphilis during cicatrization, the rigidity of the walls permitting the introduction of the endoscope into the healthy urethra beyond; 66, Epithelial thickening of the mucosa in stricture after partial dilatation; 79, Stricture, with a bridge apparently two openings into the urethra beyond; 81, Stricture of long standing after thorough dilatation (22, Charriere); 82, Urethral polyp on the posterior wall of the urethra; 97–101, Pictures taken from an urethral carcinoma; 103, Posterior portion of a diverticulum on the lower urethral wall; 102, Tumor of the mucous membrane of the bladder in cystitis; 108, Cicatrix following a vesico vaginal fistula.

Notwithstanding all this, however, the endoscope has hitherto been chiefly applied to the examination of urethral diseases, and since the cases where its use in this connection is of great practical value are the exception, I will only consider its application in the modified form which I have ventured to construct.

The endoscope which I have had made (Fig. 1) differs from Grünfeld's, first, in having a 30-calibre determined by that of the normal urethra, 30 to 33, Grünfeld's tubes never being made larger than 24, and averaging from 18 to 20. Second, in the obliquity of its visceral opening, so that inspection in all directions is made possible by the protrusion of the bladder wall or mucous membrane into its orifice. Grünfeld's straight, fenestrated tube has the window set in at a slight angle, in order to avoid light reflexes, but that author recommends only the tubes cut off at a right angle to the axis for general use, and never any with more than a slight variation from a right angle. Such tubes are undoubtedly best for urethral examination. Third, in being particularly designed for the inspection of the bladder, and permitting what has hitherto not been done, the introduction of instruments through an endoscope into the male bladder, so that, as with the forceps which I have had constructed for the purpose, a foreign body might be removed in this manner, instead of by operation, or with a lithotrite.

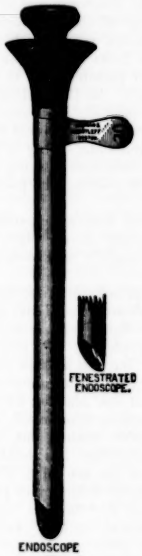
For the female bladder and urethra the instruments are similar, but much shorter, and may be of larger calibre. The external orifice of the female urethra, however, is not always larger than that of the male, and often requires forcible dilatation before admitting the introduction of instruments of large calibre.

My instrument is principally designed for the detection of foreign bodies and growths in the bladder, and as an aid in the solution of obscure symptoms of urethral and bladder disease. The fenestrated tube may be used with advantage in preliminary examination, as the mucous membrane and its vascular supply are much better seen in the full bladder. The open tube is used in the empty bladder, absorbent cotton or sponge tampons may be carried down with the forceps, or tampon holder, to dry the surface or remove any collection of urine.

Grünfeld, on the 208th page of his work, says: *An die Einführung von Instrumenten in die Harnblase unter Controle des Endoscops sowie deren Verwendung daselbst konnte aus begreiflichen Gründer nicht gedacht werden.* "The introduction of instruments

into the (male) urinary bladder, under control of the endoscope, as well as their application there, was, for apparent reasons, not to be thought of," and states further on, that his investigations have thus far been confined chiefly to the female bladder, easier of examination, but much less often the seat of disease. I have found no difficulty in introducing this instrument into the bladder of the living subject without ether, but would recommend anæsthesia for all bladder exploration. In urethral examination the local anæsthetic effect of cocaine suffices.

The use of the endoscope is not by any means limited to the examination of the urethra and bladder, but may be employed with advantage in exploring numerous other cavities, such as that of the uterus, the rectum, high up, the nasal and pharyngeal cavities; and, also, sinuses and cavities following disease or injury. I see no reason why, introduced as a trocar



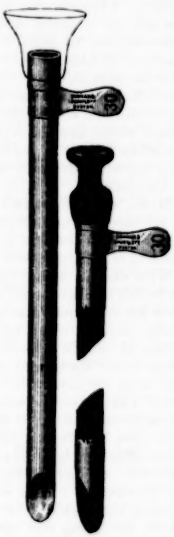


Fig. 1.

Fig. 2.

canula, or through a slight incision into the abdominal or thoracic cavities, it could not be used to advantage in the diagnosis of obscure and serious affections.

The best light to use is reflected sunlight, and the tubes may be darkened on the inside but soon become dull enough on the inner surface to avoid trouble from light reflexes. Any topical applications made in the bladder or urethra with this instrument are much better and more scientific than those made somewhat blindly by other means.

In making the ocular end of the instrument I have preferred a simple funnel-shaped attachment, passed over the end of a tube, made like those for Professor Bigelow's evacuator. The very practical indicator being convenient for manipulation, and simple in construction.

LITHOLOPAXY.

In considering the changes which the above demonstrated fact suggests in litholopaxy, we have mainly to do with the process of evacuation, and here an important alteration in the construction of the evacuator is indicated. This consists in reducing the distance between the orifices of the present tube, that is the combined tube, made up of the part for insertion and the joints connected with the evacuator, from 15 3-4 inches to 10. In order to be evacuated every fragment must be lifted by the exhaust current with the column of water from the visceral orifice to the opening in the trap end of the tube, and that to materially shorten this distance much adds to the admirable working of Professor Bigelow's instrument, is readily understood.

Another, and what seems to me valuable, modification in the evacuating tubes is to have them made so as to be introduced with a staff and have left when this is withdrawn a tube with an orifice representing more than its full calibre and corresponding with it in direction (Fig. 2), so that the fragments, instead of entering the tube at an angle, are drawn directly into its orifice by the exhaust current. The obliquity of the opening is such that the bladder is held away by the extremity of the tube and is only drawn in when the latter is so placed that the orifice lies close to the wall and in a parallel plane, and under these conditions the bladder will be drawn into the orifice of any tube. A most valuable adjunct to the evacuator, however, and one which readily prevents aspiration of the bladder wall, or "fish bite," under ordinary circumstances, is Professor Bigelow's supply-pipe attachment, by means of which the volume of water in the bladder during operation may be quickly regulated to such a nicety that the tension of the bladder wall may be always kept where aspiration is practically out of the question.

In order to shorten the tube to a length of ten inches from the visceral orifice to the end of the trap, it is necessary to omit the first joint, which, with my tube, is not needed. When the guide is withdrawn, the outer end of the tube should be elevated so as to be as much above the bladder level as possible, and the thumb placed over the orifice until the bulb is attached. In withdrawing the tube it is unnecessary to detach it from the evacuator. A little manual dexterity is thus, in part, substituted for a joint which, although it gives a finish and neatness to the apparatus and operation, is not necessary, and increases the distance which a fragment must travel in order to be caught safely within the bulb. The accompanying drawings illustrate the tubes as described. The evacuating tube is readily converted into an endoscope by attaching the ocular piece. This and the staff are made of hard rubber and the instrument is thus very light. It would seem, perhaps, that the edges of the orifice are sharp enough to cut somewhat during manipulation, but such is not the case. The canal of these tubes being perfectly straight any impacted fragment can be readily removed and the tubes can be thoroughly cleansed by forcing through them a tight wad of cotton or sponge with the staff. These tubes also admit of the passage of larger fragments than the other tubes of a corresponding size. Their simple construction makes them much cheaper than Professor Bigelow's tubes. The object of these changes is naturally to increase the rapidity of evacua-

tion, and thus add somewhat to the efficacy of the evacuator which Professor Bigelow has already made so beautiful in its working. To any one who has studied its capabilities, by evacuating coal fragments from a glass globe, for example, and seen with what certainty they, sooner or later, are captured, I am not putting too frequent stress or compliment, if either be needed, upon the Bigelow evacuator.

If it has been my good fortune to contribute somewhat to the efficiency of this instrument, I must refer the same to the opportunities which a double service, as Dr. Bigelow's House Officer gave me, to become familiar with litholopaxy.

Compared under like conditions the modified evacuator removes fragments four or five times as rapidly. In a protracted operation this is, of course, a great advantage. My friend, Dr. Beach, of the Massachusetts General Hospital, has kindly used these tubes in the removal of a small stone, the fragments of which weighed 14.7 grammes. The working of the instrument was most satisfactory. I have also tested them thoroughly in evacuating fragments from the bladder of a dissecting-room subject, Dr. Whitney, the curator of the Warren Anatomical Museum, having been good enough to furnish me with a calculus.

If shortening and increasing the diameter of the shaft of a lithotrite add to its efficiency in any way, it would seem that the same urethral measurement might be taken into consideration in its construction. The length of divulsors should also be diminished so that the possibility of forcing them through the urethra into the bladder wall would be eliminated. Six inches is, I believe, sufficient length for any divulsor, and such a one is now being constructed.

CATHETERIZATION.

While an evacuating tube or an endoscope should be as short as possible, a catheter may be of any convenient length, and just what this is has probably been determined by making the instruments sufficiently long to give a good chance for manipulation, and leave length enough beyond the part grasped by the hand for introduction into the bladder. The standard length of catheters has thus been determined, and it is interesting to notice that nearly all urethral and bladder instruments, such as sounds, evacuating tubes and divulsors correspond in length to the ordinary metallic catheter. When, however, a catheter or tube is to be employed for washing out the vesical cavity, it should be as short, and of as large calibre, as possible, so as to best admit of the free passage of fluids and thick mucus, or other matter. In the introduction of urethral instruments it is perhaps well to remember that any elastic tube as it becomes attenuated diminishes the calibre of its canal, while on the other hand, an approximation of its walls in the longitudinal direction increases the same.

— Sir Andrew Clark has resigned from the staff of the London Hospital, where his service as physician had extended over a long period of years.

— A statue in memory of "Sister Dora" was recently dedicated in Walsall, England, the cost having been defrayed by Miss Lonsdale out of the profits which she had received from her biography of her deceased friend.

A CASE OF SUPRA-PUBIC LITHOTOMY.[1]

BY M. F. GAVIN, M.D.,
Visiting Surgeon, Boston City Hospital.

THE so-called modified high operation for the removal of stone from the bladder is still *sub judice*, and every case reported will assist in determining its proper place in practical surgery.

There can be no doubt of the advantage of the suprapubic operation as improved by Professor Petersen in some cases, as with large stones, especially when they are hard, in the very fat where it is difficult to reach the bladder through the perineum and those complicated with disease of the kidneys, or enlargment of the prostate, and where from paralysis or anchylosis of the lower extremities it is difficult to place the patient in the lithotomy position. The present question is not to determine its application to such exceptional cases, but to find out how far the operation should succeed perineal lithotomy and litholapaxy. I suppose the advantage of the high operation are the rapidity and readiness with which the operation can be done, freedom from the danger of troublesome hæmorrhage and no possible risk to the vesicular seminales or their duct. In the following case litholapaxy was out of the question by reason of the diminished size of the urethra, while perineal lithotomy, would have been nigh impossible, owing to the partial anchylosis of the lower extremities, leaving the high operation the only means of ridding the patient of his stone.

M. C., about forty-two years of age, an ex-soldier of intemperate and dissolute habits in the past, an opium-eater at present, and thoroughly broken-down, was first seen June, 1886.

With exception of repeated attacks of gonorrhœa his health had been good until about three years ago, when his spine was fractured in the lower dorsal and lumbar regions, resulting in paraplegia. He was an inmate of the City Hospital for months at that time, being finally discharged as incurable. For about one year after his injury he emptied his bladder by the use of a catheter; the urine becoming ammonical, was recommended to have his bladder washed out, and ever since the greater part of his urine has dribbled away, although he still continues the use of a silver catheter. Of late, he has had great difficulty in passing the catheter; as he expressed it "there is something against which the instrument strikes," and to relieve him I was sent for. His condition was one of extreme filth, contents of bladder and bowels besmeared his perineum, inside of thighs and genitals: his wife having died of phthisis, none but young children had been left to attend to his wants, which accounted for the deplorable condition he presented.

There were two fistulous openings in the urethra, no doubt due to violent use of the catheter; one was in the penile portion and a second at the junction of the scrotum and perineum, through which the urine constantly ran; the perineum appeared fuller than normal. The urethra after division of meatus showed the presence of a stricture in the membranous portion permitting the passage of a No. 10 English catheter: a small size sound was introduced with difficulty into the bladder but could be only partially rotated owing to the constricted and thickened bladder. A large stone (possibly more than one) was detected, and

[1] Read before the Boston Society of Medical Observation, Oct. 4, 1886.

lithotomy recommended. Three months later, on September 8th, 1886, the patient entered the City Hospital. His condition at that time was about that described, except that he had had diarrhœa for several days.

Under the use of salicin, restricted diet and cleanliness, his condition was so far improved as to allow Petersen's operation to be performed on the fourth day after entrance. For two days before the operation unsuccessful attempts were made to wash out the bladder with a warm solution of boracic acid.

Operation. The usual antiseptic precautions were used. The patient was etherized. A pyriform-shaped bag, well greased, was introduced into the rectum and inflated. The bladder was injected with about ten ounces of warm solution of boracic acid. A rubber ligature around the penis was powerless to keep the bladder distended, as the greater part of the injected fluid came away through the fistulous openings. The distension of the bladder was therefore very imperfect, and the advantages of rectal distension not fully attained. A vertical incision four inches long, was made in the median line above the symphisis: after division of skin, linea alba and fascia transversalis, the knife was dispensed with. The bladder was found readily down in the pelvis, and was now seized with tenaculum and held while an incision of about one and a half inches long was made. Two stout ligatures were at this stage passed through the edges of the wound in the bladder and given to an assistant to hold. The finger was inserted into the bladder and detected the presence of two stones. Both fore-fingers were now introduced in the manner recommended by Sir Henry Thompson, and an effort made to extract the stones but without success. The wound in the bladder was enlarged, lithotomy forceps introduced, and another effort made to dislodge the stones from a pocket in the thickened walls of the bladder; the air bag was now removed from the rectum and the finger of an assistant passed within the sphincter lifted the stones, which were then seized by lithotomy forceps and extracted. A large quantity of gravel-like detritus was removed and the bladder thoroughly irrigated. No attempt was made to suture its walls; ligatures were allowed to remain for twenty-four hours. Two sutures were passed through each angle of the wound, a thick pad of iodoform gauze applied with pressure. The peritoneum was not seen during the operation. The fistulous opening in the perineum was curetted and packed with iodoform gauze. The subsequent care of the case resolved itself into irrigating the bladder, attention to personal cleanliness and supporting the patient. No symptoms of cellulitis or extravasation of urine appeared. Urine came through abdominal wound in diminished quantity until October 6th, when the wound was practically healed. The temperature never exceeded 99°. Great relief from pain followed the operation with marked improvement in the general health of the patient. The fistulous opening in the penile part of penis healed over, that in the perineum is not quite healed, but no water comes through it. The patient was discharged from the hospital October 16th. The stones that were removed were very different in appearance; the larger being quite rough and crumbly on surface and of a dirty grayish color, the other being smoother, harder, and heavier in proportion to its size. Total weight, eight hundred and twenty-seven grains.

A CASE OF SUPRA-PUBIC LITHOTOMY.[1]

BY A. T. CABOT, M.D.

The patient, a man of forty-nine years, entered the Massachusetts General Hospital, September 7, 1886, with the following history: He was in good health up to eight years ago, at which time he began to have pain and difficulty in micturition. This trouble gradually increased, the pain being often very severe after passing water, and urination became very frequent. He has noticed blood in the water but once.

During the last two years his sufferings have been extreme; he has been confined to the bed much of the time, and has become addicted to the use of opium.

During the last eight months his stream has been getting very small, and he has been in the habit of using bougies to obtain relief. Attempts by physicians to reach the bladder have been unavailing, and have caused considerable bleeding from the urethra.

He was, at entrance, very much emaciated, and was troubled by chronic diarrhœa, which was accompanied by great pain through the rectum and bladder. The urine, which passed in a very small stream, almost by drops, was extremely foul, ammoniacal, and loaded with pus. A stricture arrested the sound behind the scrotum; the prostate was somewhat enlarged.

On September 11th, ether was administered, a fine filiform bougie was, after some difficulty, passed through the stricture, and it was divulsed. A searcher was then introduced, and a large stone was felt.

The lithotrite did not pass easily, but was caught in false passages, one of which was of considerable length. After a long, careful trial, it finally entered the bladder and grasped the stone, which was hard, and measured two inches in the diameter seized.

It was evident that with so large and hard a stone, and with a urethra offering such obstacles to the passage of instruments, litholapaxy would be unwise, and the size of the stone made the supra-pubic incision the preferable one among cutting operations.

No rectal colpeurynter was at hand, so that nothing further was attempted on that day.

September 15th (two days later), supra-pubic lithotomy was performed as follows: The patient being etherized, a gum-elastic catheter was introduced, and a rubber band was tied snugly around the penis, to prevent the escape of water. The bladder was emptied, washed out, and then filled with a two per cent. solution of boracic acid. Without any forcing, it held sixteen fluid-ounces, and even then, the supra-pubic region was tympanitic to percussion.

The colpeurynter, which had been introduced into the rectum, was now slowly filled with water until fourteen fluid-ounces had been thrown in. As the rectal bag filled, the bladder could be felt more and more distinctly above the pubes, and the percussion over it became duller, though never reaching flatness.

An incision three and a half inches in length was made from the symphysis pubis upwards, and was carried down between the muscles into the prævesical space. The peritoneum was then seen to reach down nearly by to the pubes.

At first this was not easy to draw up, but after incising a thin fascia below it, which seemed to be the prolongation of the transversalis fascia (fascia propria of Velpeau), the left forefinger could be hooked under

[1] Reported to the Boston Society for Medical Observation, October 4, 1886.

the peritoneal fold, and this was easily drawn out of the way while the bladder was incised.

The finger of the left hand then followed the knife into the bladder, and by it the vesical wall was readily held up while the incision was enlarged to the necessary extent. The stone was then seized and extracted. It was very hard, heart-shaped, and weighed 1,180 grains.

There was no hæmorrhage of any account. Two rubber drainage-tubes were introduced, and as the water was allowed to escape from the rectal bag, they were carried down with the floor of the bladder as it sank into the pelvis. They were then secured in place by stitching them into the lower angle of the wound, and the bladder having been again thoroughly washed out, an antiseptic dressing, with iodoform gauze next the wound, was applied.

The drainage-tubes were left of sufficient length to be carried over the side of the bed into a bottle, and by their syphon action they kept the bladder empty. The dressing was changed daily, and irrigation was practised twice a day with a boracic solution. The double tube made this possible without disturbing the dressing.

For the first twenty-four hours after the operation there was considerable pain, probably exaggerated by the patient, and more difficult to control on account of his previous morphia habit.

It is of interest to note how slight and of how short duration was the fever following the two operations. The morning following the divulsion of the stricture the temperature was 101°. The next morning it was normal, and in the evening following the operation for stone it reached 102.4°, but after that never exceeded 100°.

On account of the disabled condition of the urethra, the drainage was kept up longer than would usually be necessary. One tube was removed on the twelfth day, and the remaining one on the fifteenth day after the operation.

A sound (about No. 25 French) was passed, and slipped easily along into the bladder without catching in any of the false passages. The wound rapidly contracted, and the greater part of the urine passed by the urethra.

On the twentieth day after the operation the patient was up and about, with only a small, fistulous opening where the wound had been, and on the twenty-sixth day he went home by his own wish.

There is some interest attaching to the indications for the selection of the appropriate operation in this case. The effect of false passages in increasing the risks of a litholapaxy I have never seen mentioned, and yet, in case of a stone of any considerable size, their existence so complicates the operation as to add greatly to its dangers.

In the case that I have reported, had the stone been of moderate size and of soft consistency, its removal could have been effected with perhaps two introductions of the lithotrite, and two more of the evacuating tube, and with care, this amount of manipulation would have been possible without serious injury to the urethra, but with a stone of the size found, the repeated introduction and prolonged use of instruments would have been required, and would have caused great damage to the parts. Lithotomy was, therefore, indicated, and the size of the stone made the suprapubic method preferable.

RECENT PROGRESS IN PATHOLOGY AND PATHOLOGICAL ANATOMY.

BY WILLIAM F. WHITNEY, M.D.

THE PHYSIOLOGICAL FUNCTIONS OF THE MARROW AND ITS RELATIONS TO DISEASE.

THE interest which has been aroused of late years from the discovery by Bizzozero and Neumann of nucleated red corpuscles in the marrow and the changes which have been noticed in it in association with pernicious anæmia have induced Geelmuyden [1] to take up the subject.

It has been known for a long time that in mammals during their fœtal condition the red-blood corpuscles were provided with nuclei, and that this is a persistent condition in the lower vertebrates. In the fœtus they are found in blood, but in the greatest numbers in the liver and spleen, and these two organs have been regarded, therefore, as their place of development. They occur first in the marrow in extra uterine life, while they disappear at this time from the blood and organs. From these premises Bizzozero and Neumann naturally drew the conclusion that this was the source of their supply after birth.

Before giving the results of his own work a brief description of the generally-received details of the kinds and structure of the marrow is given, as essential to a clear understanding of the subject.

Three sorts have been distinguished. The yellow or fatty, the red or lymphoid, and the gelatinous marrow. The last is found only under pathological conditions: the first occurs in the adult, in all the bones of the extremities, even in the spongy ones: while the red marrow is restricted to the bones of the trunk, namely, the vertebral column, ribs and sternum.

The cells of the red marrow vary greatly in form and character. If a fresh preparation is examined in a three-fourths per cent. solution of common salt there is seen a mass of round cells of all sizes. The protoplasm of these is partly homogeneous and in part contains a number of refractive granules. In close relationship with these stand the so-called nucleated red-blood corpuscles. These are small, more or less hyaline cells, more or less colored with hæmaglobine. At times they contain two distinct nuclei and the cell body shows indication of a line through the middle as if about to increase by division. Sometimes the nuclei are found partially protruding from the protoplasm, and even look as if lying free in a saucer-like depression. The author does not assert that the nucleus is lost in this way, but he has found nothing to support the older theory that it breaks up into granules and is dissolved, undergoing in this way, a sort of atrophy. Large granular cells with a complicated nucleus, called myeloplaques, are always found in the marrow. These lie imbedded in the parenchyma and are to be distinguished in many ways from the osteoclasts lying close to the walls of the medullary spaces. Besides these there are spindle and star-shaped connective tissue cells, more or less rich in protoplasm, in large numbers.

Of especial interest are the pigmented cells and those containing blood corpuscles, in as far as they represent marked degeneration of the latter. The number thus contained may vary from one to twenty, but in rare instances as many as fifty have been counted in a single cell. In these all the steps of de-

[1] Virchow's Archiv., Vol. 105, p. 136.

struction can be followed, beginning with the perfectly fresh red-blood cell and ending with the clump of pigment.

In order to obtain a clear idea of the distribution of the blood, about which there is dispute, bits of bone were carefully decalcified and sections made from this.

In the yellow or fat marrow there were found widely scattered vessels lying between the fat cells, which were closely pressed together. As a rule the pure fat marrow only fills a part of the cavity of the long bones, and alternates with that of which the color is paler or a more diffused red. This color is found to depend either upon a simple hyperæmia or a partial infiltration with round cells. The walls of the vessels are seen as five dark lines. These are capable of very little resistance, as is shown by the extravasation of blood, which are frequently found penetrating for some distance between the somewhat atrophied fat cells.

In the lymphoid marrow the fat is reduced to a small number of widely separated droplets. But as a support for the otherwise loosely adherent cells, there is a network of star-shaped anastomosing connective tissue corpuscles. A similar plexus of dilated capillary veins is again noticed, and close to these extensive extravasations of blood. In extreme anæmic conditions the lymphoid marrow consists almost entirely of an intimate mixture of medullary cells and red-blood corpuscles. The thin-walled veins can no longer be recognized.

In diseases which are associated with a marked decrease of fat tissue, that is, cancer and tuberculosis, that in the long bones also disappears. The space thus left is not filled with round cells and blood so as to form a lymphoid marrow, but is replaced by a light yellow, transparent, more or less firm, gelatinous mass. In extreme cases this does not occupy all the space, and the small round fat cells with their nuclei, surrounded by a layer of protoplasm look as if lying in an excavation of the matrix. In the spongy bones this form is rarely seen, the lymphoid cell elements completely covering it up.

In the investigations of the author on the conditions of the marrow in disease, he has paid especial attention to that of the long bones, and to the occurrence of the nucleated red corpuscles and pigmented cells in the spongy bones. The importance of this is clearly manifest, since that of the hollow bones often changes into an embryonic state similar to that of the spongy bones, which are regarded as the source of blood formation. The above-mentioned cells are to be regarded as an expression of regeneration and destruction of the red-blood cells.

If it is really so that the red corpuscles are formed in the bone marrow, then those diseases in which we would expect a characteristic change here, are those associated with anæmia and in which the number of corpuscles has been greatly reduced. Yet in these diseases the hollow bones are found filled with red marrow. In such cases the entire volume of this marrow is increased and all the conditions are present for an increased production of red corpuscles. This increase, therefore, of red marrow must be regarded as a secondary compensatory change, called into existence by the anæmia. And this last can only be explained by an increased destruction of red cells somewhere in the organism.

This assumption is greatly strengthened when the conditions found in pernicious anæmia are taken into account. The chief symptom of this is a marked diminution of the red-blood corpuscles and the development of a lymphoid marrow in the long bones as a rule (82 per cent. of all cases). The nucleated cells present are fewer in number than in normal individuals, but their number is, however, much larger than in most diseases.

The fact that these are occasionally wanting seems at first sight to go against the idea, that places the regenerative power in the medulla of the bones. But when it is remembered that in cases of acute anæmia from loss of blood, they are always present and often in large numbers, their occasional absence in chronic anæmia should have little weight. For in the latter case the individual has been pulled down, and the activity of the cells in general is very much reduced.

In pernicious anæmia there are found great variations in the intensity of color, size and shape of the nucleated cells, and the non-nucleated corpuscles follow very closely upon them, thus pointing to their origin.

Another peculiarity of pernicious anæmia is the frequent occurrence of large cells containing blood and pigment. Surprising as it may seem, it must nevertheless be conceived that a destruction of red cells takes place in the marrow, and may assume such proportions as to equal the regenerative process. This he also regards as a secondary phenomenon dependent upon the exceptional conditions of circulation. The bed of the blood stream is extremely widened, and the current in consequence very much slowed. If, as often happens, extravasations take place, then further difficulties must be thrown in the way, and a true stasis result. As takes place in the other parts of the body, the white cells come in to aid in carrying off this blood, and in this manner the large cells above mentioned are brought into existence.

He closes his paper with an account of his investigations on various animals for the purpose of establishing the presence of intermediate forms. This was chiefly done by rendering the subjects anæmic and then killing them after varying periods. As a whole his results are not conclusive, although they tend to show the presence of such forms.

In union with other observers he found that the spleen became markedly atrophied, but it did not contain red-blood corpuscles more or less deeply furrowed such as were found in the normal spleen. These peculiar bodies he regards as representing a form of degeneration. This, it appears, is interrupted as the individual becomes anæmic, for the organism has immediate need of the entire quantity of hæmoglobine over which it has control to supply the loss from the hæmorrhages. So this atrophy of the spleen must be regarded as a sort of inactive period.

Accompanying the article is an excellent list of the literature pertaining to the subject, and the different forms of cells described are well illustrated in the plates.

ANATOMICAL INVESTIGATION AS TO THE ORIGIN OF VESICULAR EMPHYSEMA OF THE LUNGS.

Two different theories have been advanced about the process lying at the bottom of this. The one takes a purely mechanical activity as point of departure, while the other presupposes a vital, nutritive disturbance. In the first an increased pressure is the

main point, whether it is referred to inspiration or expiration. About the nutritive disturbances there is greater difference of opinion. Some regard it as a modification of the blood current, others as a chronic inflammatory process with subsequent fatty degeneration. A third party blame the nerves leading to the lungs, and speak of a trophic neurosis. While yet others think that the disease begins with a primary destruction and thrombosis of the capillaries.

Klasi [2] has made a careful analysis of the different opinions controlled by observations and experiments of his own.

Before summing up the results of his own work he recalls a few of the histological points which seem to have a special bearing.

The alveoli are covered with a continuous layer of epithelium which presents itself in two forms: (1) Large non-nucleated scales, without protoplasm, and (2) small cells containing protoplasm. (Interpolated cells.) All the authorities agree in saying that the nuclei of the cells lie in the meshes of the capillary network, varying in number from one to three. It remains now to be settled whether these cells are confined to the meshes or whether they spread over the vessels with a scale-like expansion. From his studies the author is inclined to the first view.

What are the peculiarities of the epithelium and what are its functions? As to this, his observations support the view of Arnold, who considers that it is of marked thickness, and that it furthermore has elastic properties. This is rendered almost certain when the displacement to which the capillary net is subjected during respiration is considered.

About its functions very little is positively known. The supposition is that it serves as a support to the capillaries, and also aids in regulating the amount of fluid.

The basement membrane is found as a thin, quite homogeneous membrane, provided with scattered nuclei and in which the elastic network of fibres with their branchings are imbedded. Finally, Arnold has made us acquainted with a well-developed lymph system with more or less complete gland-like accumulations. He has further shown how this envelopes the finest arteries and bronchioles like a sheath, and from there sends prolongations between the septa, and are even to be found isolated within them.

The first stage of emphysema shows itself in an increase in the size of the vascular meshes and a heightened activity of the epithelium. This latter is explained as reaction to an irritation, which must be regarded as the excessive expansion. This persistent and continually increasing pressure soon brings about the opposite effect. The epithelial cells are torn through the cement which unites them to each other as well as from the capillaries. This loosening and separation soon leads to a degeneration of the cells, from disturbance of nutrition or of the amount of water contained in them. They are then reduced to a thin lamella, which are capable of very little resistance, especially in the alveolar septa where the defect is first noticed. This disappears by absorption or degeneration, and the finest elastic fibres lying in it either disappear or retract and surround the opening. The larger this is, the thicker will be the surrounding layer of fibres, which can have originated by being pressed one against the other. Where there is abundant connective tissue as between neighboring infundibula, there is also a defect to be expected. This destruction of the epithelium leads at the same time to a loss of the capillaries. They have lost their support. They are exposed in consequence to increased pressure, to greater stretching and pulling, since they are only attached to a thin membrane. By this, their lumen is reduced to a minimum. Finally, this thread, which for a long time has not allowed any formed elements to pass, is broken. The walls collapse, degenerate and disappear. Numerous injected preparations illustrated this finely.

The elastic tissue possesses the characteristics which can increase the process started by the epithelium. The author believes less in a real atrophy of this very resistant tissue than in a pushing aside of it and a displacement of its fibres, which can simulate an atrophy. The connective tissue nuclei which have been mentioned by some as evidences of inflammation he regards as simply lymph cells.

In these observations he differs from the previous observers who thought they saw the commencement of the process in a primary disappearance of the intra-capillary elastic network, rather than in the degeneration of the epithelium with rarefaction of the capillary loops.

As to the etiology, he is inclined to the purely mechanical explanation of increased pressure. Without, however, denying that other diseases may have an influence in weakening the lungs, he regards a nutritive disturbance alone as insufficient..

INVESTIGATIONS ON THE TERMINATIONS OF THE MOTOR NERVES IN THE VOLUNTARY MUSCLES.

Miura [3] has made observations on the anatomical changes after the use of curare, which is well known to cause a paralysis of the nerve-endings on the muscles. For his experiments he employed frogs and lizards during their torpid condition in winter. In this state the failure of the respiration, which ordinarily makes long observation impossible, is not noticed. Thus he could keep the animals alive for from twenty to fifty days after poisoning. By the aid of control observations he found that the nervous plexus of the terminal plates appeared extremely thinned, atrophied. It colored weakly, so that in many places it seemed as if broken through. The so-called granular substance was much reduced, and in like manner was only feebly colored. The basement nuclei as well as those of the muscles were neither increased nor diminished.

This he regards as of the nature of a simple atrophy, and not a degeneration, as has been described. The heart, in spite of the great doses of curare, continued to work uninterruptedly, while the muscles of the body were completely paralyzed.

[3] Virchow's Archiv., Vol. 105, p. 129.

ON THE NATURE OF THE SO-CALLED HYPERTROPHY OF THE PROSTATE.

Thompson [4] from his own observations post-mortem divides the enlarged prostate found in elderly people into four groups.

(1) An increase of the glandular tissue and stroma in the relations corresponding to the normal. True hypertrophy. This is comparatively rare and causes no especial increase in size of the organ, which can present abundant secretion and large concretions.

[4] British Medical Journal, 1886, p. 1156.

(2) A new formation composed almost entirely of connective tissue with a tendency of the gland tissue proper to rarefaction. This gives the fibrous hyperplasia, or where the smooth muscular fibres do not remain behind in their increase, the fibro-muscular hypertrophy. This is the ordinary form, which has great increase in volume, but little secretion and formation of concretions.

(3) Great increase of the glandular part over the hypertrophy of the stroma. Abundant secretion and concretions are characteristic of this rare "glandular hyperplasin."

(4) Increase of the gland tissue and stroma in proportions corresponding to the normal, but with the production of circumscribed tumors. This well-known "local hypertrophy" can be established in a normal as well as any kind of hypertrophied prostate.

ADENOMA OF THE PLACENTA.

Klotz[5] describes a disease which seems to lead to abortion, with retention of the placenta, and consists in new formations of the character of adenoma.

Microscopic examination was made in five cases of retention after abortion, and in three the peculiar formation was found. The point of departure appears to be in the glandular layer (stratum spongiosum) of the decidua serotina. The earliest change is found to consist in the transformation of a portion of its connective tissue into a gelatinous mass of protoplasm, of an embryonic form, and of its glandular epithelium into a stratified layer. This last is composed of elongated flat cells, which are to be distinguished from the decidual cells of the same general shape by their greater length, and by the smallness of their nuclei.

As soon as the epithelium commences to form, there is produced a great number of nuclei. If a double staining has been used, they take the blue color of the hæmatoxylin, while those of the decidual cells retain the carmine color.

The mass of tissue thus run together grows in the form of buds, villi, or knobbed projections. Further growth and repetition give rise to trunks with branching shoots. These twist into each other, on account of the restricted space, forming ball-like masses, and thus the nodules of adenoma are produced.

In one case there was a recurrence in six months after removal, which presented the same histological structure. Repeated removal and cauterization with nitric acid resulted in healing.

The author believes that the adenoma is formed before the expulsion of the fœtus, and that it is the cause of its death and abortion, and he further thinks that the retention is due to this also.

TUBERCULOSIS OF THE TENDON-SHEATH.

Berger[6] gives a clear description of this rare affection, founded on four cases. He distinguishes between the acute and chronic form, and in both separates the purulent from the non-purulent. Of the first, up to the present time there has been no observation, and it can only occur now and then, as the accompaniment of general acute miliary infection.

The chronic disease is either quite diffuse, or else circumscribed. In the former, there appears a swelling throughout the entire extent of the sheath. This increases very slowly, and only causes destruction when it has attained considerable size. The tumor is a soft, sarcomatous-looking mass, surrounded by a sort of capsule, and entirely filling the lumen. On microscopic examination, the characteristics of tuberculosis are to be made out.

The latter form, the seat of which is preferably near the end of the sheath, presents circumscribed nodules, up to the size of a walnut.

In both kinds the subsequent course is the same. A destruction of the capsule and the skin comes on. The fungous masses spread more widely, and can finally suppurate. The general condition becomes worse and worse.

Much more frequent it is a secondary tuberculosis, which may follow a primary form elsewhere (usually of the bone). The sheaths of the tendons of the fingers are affected preferably with the primary form, while those of the peronei and the extensors of the foot are most frequently the seat of the secondary affection. The treatment has to be guided by the form of the disease. In two cases in which the common carpal sheath of the flexors was involved, amputation had to be resorted to. In the other cases, extirpation of the tumors was sufficient.

TUBERCULOSIS OF THE MUCOUS MEMBRANE OF THE MOUTH.

Within a few years, cases of this peculiar affection have been reported, and Hansemann[7] has taken up the subject, in view of the importance of the diagnosis. This is often of great difficulty, and cannot be made by mere inspection, and is easily confounded with cancer or syphilis. None of the symptoms of pain or redness can be relied upon, or the appearance of tubercles at the base of the ulcer to differentiate it from lues, and even the fact of healing under internal treatment is not positive, as tuberculous ulcerations at times heal spontaneously. The previous history and the manifestations in other organs must naturally be important factors.

Still more difficult, is the diagnosis between it and cancer. Age and so-called cacexia are not to be relied upon. Cancer is said to be single, tuberculosis multiple, but cases of the author show that this is not without exception. The quickness of growth, the examination of the bottom of the ulcer, and the possibility of squeezing out epithelial plugs may be indications, if they are present; also the presence of bacilli in the secretion, but this is very doubtful. An absolute diagnosis can only be made by a microscopic examination of a portion of the growth that has been excised.

In the colored preparation, the tubercles can be detected with the unaided eye as small, round spots more deeply stained. These lay usually beneath the mucosa, at times within it. Where the membrane was entirely infiltrated or destroyed, granules were often seen in the subcutaneous tissue, and even within the muscular substance. They differ but little from each other, and all show the characteristic structure of miliary tubercles. They consist almost entirely of lymphoid cells, between which are a few epithelial cells; in the centre, is very apt to be found a giant-cell. In places they are confluent. Cheesy degeneration is rarely present, and in but small amount. Bacilli were found, but, as would be expected, but very sparingly. These lay unmistakably in the giant-cells,

[5] Archiv. f. Gynæcol., Vol. 28, p. 1. Ref. in Fortschritte der Medecin, Vol. 4, p. 564.

[6] Berger. Deutsche Zeitschrift, f. Chirurgie, Vol. XXI, p. 3

[7] Virchow's Archiv., Vol. 103, p. 264.

and were also found in the midst of the tissue where there were no characteristic tubercles.

From his observations, he concludes that the affection is not so seldom as is generally supposed; secondly, that a positive and early diagnosis can only be made by means of the microscope.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

C. M. GREEN, M.D., SECRETARY *pro tempore*.

OCTOBER 25th, 1886. The President, DR. F. W. DRAPER, in the chair.

DR. H. H. A. BEACH reported the following cases and exhibited the specimens:

STONE IN THE BLADDER: LITHOTOMY.

Patient, a boy of fourteen. He had passed gravel at intervals for four years and complained of pain in the perineum and the glans penis whenever he passed water. This was most easily accomplished upon his hands and knees. There had been no blood voided with the urine. Micturition frequent.

The stone was removed through the usual lateral incision, and weighs 660 grains. Its longest circumference five inches, its shortest four inches.

With the exception of a small abscess in the scrotum, the wound healed without interruption, and he was discharged well at the end of five weeks.

STONE IN THE BLADDER: LITHOLOPAXY.

Patient, a man sixty-eight years old. Symptoms had existed about three years; during the past three months has had almost constant pain in the perineum, extending through to both hips, down the thighs and in the glans penis. Blood has been passed with the urine throughout the time. Stone crushed and removed.

It proved to be phosphatic and to weigh sixty-four grains. Complete relief followed its removal and the man left the hospital well seventeen days after.

DR. BEACH also reported the following case of

TUMOR OF THE BREAST.

Patient, a woman fifty-five years old. The growth first made its appearance when she was twenty years old. It was small (about the size of a hickory nut). It increased some until she was thirty years old, when she gave birth to a child. This was followed by an "abscess of the breast," when the tumor disappeared. Three years later another growth made its appearance which has grown periodically ever since. It was removed by lateral incision and weighed eight pounds.

DR. FITZ described the appearance of the specimen as follows: the tumor formed an elongated, rounded, lobulated mass, as large as a child's head and weighing eight pounds. It was easily isolated from the subjacent tissue but was closely adherent to the skin. Although dense in the main, several of the projecting lobules were soft and fluctuating.

On section the part nearer the nipple was chiefly composed of a dense, grayish-white, slightly translucent tissue, traversed by numerous fibres. The more remote portions of the growth consisted of lobules of gelatinous material, in places scarcely firmer than thick mucus, which its appearance closely resembled.

Here and there, throughout the cut surface, were irregular cavities, either rounded or slit-like, in which was a thin, watery, or a thick, slimy fluid. The walls of these cavities were lined with a short cylindrical epithelium, and frequently formed large and small polypoid and lobulated masses which projected into the cavity.

On microscopic examination the structure of the tumor was found to be composed of abundant large cells, stellate, fusiform and round, the former anastomosing. These cells were separated from each other by a homogeneous, colorless substance giving with acetic acid the reaction of mucine. Delicate fibres traversed the intercellular substance and were the more numerous in the opaquer portions of the tumor. The bloodvessels were few, for the most part small, and thin-walled. Papilliform growths, covered with cylindrical epithelium, were seen to project into small cavities, analogous to the condition to be observed with the naked eye. The tumor was of the variety to which Virchow has applied the term intracanalicular myxoma. Billroth prefers to retain the old name, cysto-sarcoma, although recognizing that its structure may be composed of other than sarcomatous tissue and that its clinical features may widely differ from those characteristic of the sarcoma.

STONE IN A FEMALE BLADDER.

DR. ELLIOT showed the fragments of a stone which he had removed by Dr. Bigelow's operation. The patient was a woman who had been hysterical for several years, and at times had had hystero-epileptic fits. She had suffered from a severe cystitis for four months and had frequently catheterized herself. At the operation the stone proved to be very soft. Among the fragments there appeared bits of paper. On passing the little finger into the bladder several jagged fragments were touched which felt like pieces of mortar; these proved to be bits of paper incrusted with lime salts. The paper clogged the lithotrite and the evacuator, so that the operation was tedious. The lithotrite worked best when used perpendicular to the patient, for in that position the part of the bladder over the anterior vaginal wall was depressed and made a convenient pocket for the fragments in front of the uterus.

The paper had undoubtedly been introduced by the patient and had served as a nucleus for the stone.

DR. WHEELER had seen a case about a year ago, in which a coil of hair constituted the nucleus of the stone. The patient had used injections very frequently for a long time, supposing his trouble to be simply cystitis. Dr. Wheeler also spoke of a specimen in his possession some years ago, a calculus removed from a young girl, in which a hair-pin was the nucleus, the stone weighing nearly two ounces. It seems that she used the hair-pin to help herself pass urine and lost it in the bladder: some twelve years afterwards the stone was discovered.

DR. J. W. ELLIOT reported

THREE CASES OF SUPPURATING OVARIAN CYSTS TREATED BY DRAINAGE.[1]

DR. WHEELER said: I think it is the experience of all who have much to do with suppurating cysts that

[1] See page 441.

the worst thing about them is the difficulty which one encounters with adhesions. Within thirty years I have seen four cases of suppurating ovarian cysts: in three of them the adhesions were not very marked. They were slight in one, and in the other two little or none. The cysts were removed, and the patients recovered. One other case I saw twenty-five years ago, of a gentleman in a neighboring city, who had a patient in that condition. I opened and evacuated the cyst, but closed the abdomen and gave up the patient on account of the extensive adhesions. This operation of course failed, and the patient was in a critical condition; but after a period of three or four months the patient insisted upon another attempt to remove the cyst. At the second attempt I again found it impossible to remove it, and found also that the cyst was suppurating. I evacuated the pus and closed up the cyst, and the patient died in three or four days. No attempt at drainage was made then; it was before the days of the drainage-tube; hence the fatal result. I think from my own observations that a suppurating cyst should be always treated with drainage; the worst difficulty to encounter is that of adhesions. If there are no adhesions, and the cyst, whether suppurating or not, can be gotten out of the cavity, it is very easy to get a favorable result under the present mode of operation.

Dr. F. H. Davenport said in these cases it seemed as though there could hardly be too much interference; that is, the moment bad symptoms appeared, that was as a rule a direct indication for some active interference. In the first and third cases reported, when the convalescence was disturbed by fever, chills and other bad symptoms, the trouble was found to be the suppuration of secondary cysts, the walls of which had not been broken down at the first operation. Dr. Davenport believed it to be a very important rule to thoroughly break up all such secondary cyst-walls and make the abscess one large cavity at the first operation. By so doing, one element of tediousness can be avoided.

When we consider that this class of cases as a rule is marked by their slow recovery, the sinuses often taking years to heal up, Dr. Elliot's success in these three cases is very encouraging. It is undoubtedly due to the close watching, and immediate interfering at the first bad symptoms.

Dr. J. C. Warren said: It seems to me that these cases are illustrations of the surgical principle which consists in giving free drainage to abscess cavities. I mean by free drainage, such drainage as will not permit the stagnation of pus. If we have such an arrangement of tubes that we always have a flow and no stagnation, then we have conditions favorable to the process of repair. In these cases, it seems to me that it is of primary importance in treatment to drain not only through the abdominal wall, but also some dependent part. These cases are very interesting to the general surgeon as well as to the specialist, and illustrate that the general law of free drainage pertains to the abdominal cavity as well as to the other parts of the body.

Dr. M. H. Richardson asked if Dr. Elliot had ever met with any difficulty in draining through the vagina, and was answered in the negative. Dr. Richardson said that he had aspirated two cases of pelvic abscess situated in the vicinity of the right ovary, and in both cases the needle had first perforated the bladder. The bladder was not emptied in the first case, and it was thought that for this reason a deverticulum of its distended base intervened between the tumor and the vagina.

In the second case this was borne in mind, and not only was the bladder emptied as much as possible, but a sound was introduced to indicate its exact position with reference to the tumor. Yet the same thing happened, and urine flowed from the needle on slowly withdrawing it from the evacuated pus cavity. In both cases it was intended to make a free incision along the needle. In both, some difficulty presented itself so that the needle was withdrawn in time to discover where it had perforated.

The interesting point in these cases is the unusual and abnormal position of the bladder, which might be present in any case, and therefore might be freely incised.

This accident can be avoided in every case by passing the needle slowly through the parts with the vacuum applied. If it enters the bladder at any time the flow of urine will warn us not to make an incision.

In the cases referred to no bad results followed, though the needle used was large. Another case was mentioned which showed the advantage of drainage through the vagina in pelvic abscess cavities, even when already freely opened through the anterior abdominal wall.

The patient, a young woman, had had severe pelvic inflammation resulting from three abortions, which had resulted in an abscess behind and to the left of the bladder and uterus, and had formed beside an intestinal fistula.

An operation was done by Dr. Richardson for closure of the intestine by suture, and drainage of the abscess cavity. The intestine was found already closed of itself. The abscess cavity drained through the vagina. In this case there was no difficulty found in avoiding the bladder because one finger could be put into the vagina and the other at the bottom of the abscess, while an assistant held a sound in the bladder. A remarkable improvement began in the patient's local and constitutional symptoms, and she is now about well.

Dr. Fifield said: The bladder takes wonderful positions: one can hardly tell where it may not be found. Many years ago, in a Parisian hospital, a man was brought in with strangulated hernia. The attending surgeon proceeded to operate, and in doing so cut into an elongated body lying in a sac behind where the intestine had lain: a spurt of fluid followed, which proved to be urine. It is the first and only time that I ever saw the bladder in that situation, and it would seem to be capable of taking very strange positions.

Dr. Fifield then reported the following

UNIQUE CASE OF DISLOCATION OF THE RIBS.

A boy about eight years old, standing near a peddler's wagon, was thrown down by some children underneath the hind wheels of the wagon, the horse started forward, and the wagon wheel went over the child's chest, over the left chest in front. Perhaps half an hour after this, I saw him. There was then a dislocation of some three of the ribs, I don't remember the exact ribs, near the region of the heart; a dislocation forwards, the cartilages of the ribs lying behind, the ribs projecting in front. The child was described as having been very blue, livid, and gasping for breath

shortly after the accident. When I saw him he was breathing with considerable ease, but upon any attempt being made to push the ribs backward into their places, he again grew livid, and respiration threatening to cease, I was obliged to desist from my endeavors. I think I tried twice in this way and on each occasion the interference of respiration made me let him alone.

There was obviously no way of placing the cartilages in any position, except by cutting a hole, and putting the hand in. I advised to have him left entirely alone, hoping that this would restore the position. The following day the projection of the ribs was not so noticeable and within three days the projection had almost entirely disappeared, and the cartilages had resumed very nearly their natural place. Upon consulting all the works of surgery in my library, I could find no allusion to this accident, except in one of the volumes of external pathology by Barnes, and some person associated with him. In that work it speaks of the dislocation of the ribs forward, the cartilages being placed behind. It states that there is no well authenticated case on record. But one case is cited, and it is cited with expressions of disbelief in the occurrence of the accident, and the narrator is thought either to have drawn upon his fancy or that the case was so ill-observed that it was unworthy of any notice. I certainly have not ever seen it in the best works of English surgery. I find not the slightest allusion to any such accident.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

CHARLES P. STRONG, M.D., SECRETARY.

MEETING October 4th, 1886. DR. INGALLS in the chair.

DR. F. S. WATSON showed a patient upon whom he had performed an internal urethrotomy three years previous to date, and said: I wish to show this patient on two accounts, first because he is an extreme example of gonorrhœal rheumatism, and secondly because he shows a good result of the operation of internal urethrotomy by Otis's method. The history of the case, of the operation and its result is briefly as follows: J. O. B., aged forty-nine, came to the Clinic for genito-urinary diseases at the Boston Dispensary in June, 1883. Thirty years previous to this time he had had his first attack of gonorrhœa, and between that time and the present frequent attacks had occurred, each new "case" following fresh venereal exposure had been accompanied by a severe form of arthritis; the first points involved were the toes, then the ankles, knees, wrists, elbows, shoulders, and finally the dorsal vertebræ; no actual anchylosis had occurred except in the great toe of the left foot. One attack of rheumatism had been sufficiently severe to keep him confined to bed for five months.

The last gonorrhœal affection occurred ten months since.

The urethral symptoms were: a gradual narrowing of the stream of urine for a year past, gleet, frequency of micturition, fifteen times during the day, four times during the night, a good deal of pain and scalding attended the act. There was dribbling after its completion.

The normal calibre of the urethra was 30 (French), meatus 27, at 3 inches from the meatus a stricture well formed, of one-half inch in length, and of a calibre of 23 (French).

The urine is normal except for the presence of a small quantity of blood and pus, and some mucous shreds.

He was sent to the Carney Hospital, kept in bed for two days, on a preparatory treatment of potass. citrat. and quinine.

The stricture was then divided to 31 (French), with an Otis's urethratome, and a No. 31 (French) steel sound passed into the bladder. Neither hæmorrhage nor rise of temperature nor any untoward symptom followed the operation. The frequent micturition disappeared in two or three days, and on the fourth day the patient left the hospital greatly relieved. Soluble iodoform bougies were inserted into the urethra for the first three days following the operation, and quinine was given for the same period.

On the second, fourth, sixth day, and every second day for two weeks a No. 31 (French) steel sound was passed.

The patient then went away and was lost sight of for three years; to-day he again presented himself, stating that he had been greatly improved in health in all respects until three months ago, when without venereal exposure, he had another attack of rheumatism, which was very severe, and greatly exhausted him. But that he had never had any return of his urinary symptoms, and considered himself well in that respect. I examined the urethra, and found that a No. 29 (French) sound passed readily into the bladder, and that *no* recontraction had occurred at the former seat of stricture. The meatus had recontracted one number. He has never had an instrument of any kind passed into the urethra, nor has he received any other treatment directed to it since the time that he ceased to be treated by me three years ago.

It is because of the absence of recontraction of the well organized stricture, after its thorough division by the knife. That is, to the permanence of results of a properly performed cutting operation, that I show this patient. Three years ago, Dr. G. H. Tilden and I published the immediate results of this operation in about twenty cases in which he had performed it. Time enough had not then elapsed since the dates of the operations to authorize us to speak from our own experience of the lasting results of the operations. Some of these cases have since reported to us. Of my own cases, three beside the present one, I have seen from time to time, and in these three there has been no recontraction whatever; gleet has ceased, and the patients consider themselves cured. Two other upon whom I operated have proved failures, having recontracted. Of the remainder I know nothing. It is very possible that the failures may have been due to a lack of experience of the operation, they having been among the earlier one. The sum total of my experience to-day enables me to say only, that I believe that in a small majority of strictures anterior to the bulbous urethra, of wide calibre (14 French) and upward, yield results lasting, at any rate, several years without subsequent use of instruments, and perhaps permanent, while the minority will prove failures in the sense that they will recontract, and require repetition of the operation, or subsequent dilatation, at stated intervals.

DR. LANGMAID said that he considered the term gonorrhœal rheumatism in many instances a misnomer,

as he was sure in a large percentage of these cases the processes were reversed, the gonorrhœa being a symptom of the rheumatism, not a cause.

Dr. Watson replied that he could not consider the criticism as applicable in the present case as there was never an attack of rheumatism without fresh infection, and every new gonorrhœal infection produced anew the rheumatism.

Dr. Porter inquired as to the changes that had occurred in the urinary symptoms.

Dr. Watson replied that there was no complaint of any disturbance whatever in the genito-urinary tract.

Dr. Cabot stated that the treatment by gradual dilitation showed also a good percentage of permanent cures in the same class of cases as did the cutting operation, that is, when the stricture was of large calibre. In his opinion the important factor in effecting the cure was securing full dilatation of the contracted urethra, irrespective of the means by which this was accomplished, and retaining this full dilatation until the tendency to contract had disappeared.

Dr. Porter stated that divulsion produced permanent cures frequently, even without subsequent passage of the sound.

Dr. M. F. Gavin reported

A CASE OF SUPRA-PUBIC LITHOTOMY.[1]

Dr. Cabot reported a case of

SUPRA-PUBIC LITHOTOMY,[2]

in a patient with a large stone and false passages about the urethra.

He considered it important in this operation to fill the bladder before distending the rectal bag, and showed by drawings from frozen sections, how great an effect the combined distension of bladder and rectum, have in raising the prevesical fold of peritoneum and in so steadying the bladder as to make the incision into it a comparatively simple matter.

He thought that when it was especially desirable to raise the vesical floor, as in cases of tumor, it was best to use a short, pear-shaped colpeurynter which would lie in the lower part of the rectum and press upwards from there, rather than a long sausage-shaped bag which, reaching up behind the bladder would press it forward and would not lift it so much out of the pelvis.

Dr. Watson said that this operation had within a very short time been revived, and from the improvement in technique was destined to take a prominent rank in the operations for stone. In the old operation there were two dangers, septic phlegmon and opening of the peritoneum. These are now overcome by drainage and antiseptics. In the operation as performed to-day, trouble is apt to arise from two other causes, namely: pushing down in front of the bladder with the finger under the pubic bones, and an improper method of dividing the pre-vesical fat which should be cleanly cut through with the least possible disturbance, as any traction exerted upon it will disturb very decidedly the peri-vesical tissues and decrease the chances of good union in the wound.

Dr. Porter said that he wished to direct attention to a point not mentioned previously, that is, the applicability of this operation in cases of tumor of the bladder. Its usefulness was perhaps even greater here than in cases of stone. Compared with operations by other methods he had found it affording greater facility for examining and removing the tumors and devoid of many dangers. He favored injecting the bladder first as giving more perfect control of its position and exhibited diagrams illustrative of this point. Drainage in these cases was sufficiently secured by a soft-catheter after the first three days, as there was no escape of urine through the upper wound a few hours after the removal of the tubes. The operation has been done many times without dilatation of either rectumor bladder. Dittle, of Vienna, constantly operates in this way and has devised special instruments, the important one being a pair of retractors and a knife grooved to enter the bladder upon a guide. The speaker favored the use of broad and firm spatulæ and the small electric light for illuminating the vesical cavity.

Dr. Gavin stated that the question of the best method of drainage was still under consideration. Sir Henry Thompson in his series of eight cases employed drainage-tubes in the wound in four cases, and in the secondary four omitted them. All did equally well.

Dr. Blodgett said that he hoped to hear more in detail the description of methods for securing drainage after the operation of opening the bladder from the abdominal surface. It would seem that perfect drainage might have more to do with the success of the operative procedure when the viscus is opened, than in ordinary and less serious operations.

Dr. Blodgett spoke of a method of securing constant drainage of the bladder which he had seen carried out in Guy's Hospital, in a case operated upon by Mr. Howes, of London.

The patient was a small boy, who was suffering from retention, and in which it was not easy to pass a catheter, or in any ordinary way to relieve the vesical distention. The bladder was opened by the suprapubic method, and a soft catheter was subsequently passed into the cavity of the organ through the wound and gently pushed along the floor of the bladder, until the point entered the urethra. The point of the instrument was felt beneath the perinæum, and by a simple incision was exposed, and the end brought out through the second wound; thus establishing a channel for continuous and complete drainage of urine, as well as for the evacuation of any other products which might collect in or about the bladder. The abdominal wound healed rapidly, without complication. The condition of the child was good throughout, and Mr. Howes was quite satisfied with the method as a means of drainage of the bladder in cases in which for any reason this is to be desired. One point which seemed to be a feature in its favor lies in the fact that by this method the bladder is drained from its most dependent part, from the base, through the perineal floor, without wounding the prostate, or opening the deeper parts of the floor of the pelvis, thus avoiding some of the recognized perils attending any operation upon the bladder from this direction.

Dr. Langmaid read a paper on

FALLICULAR TONSILLITIS.[3]

Dr. Leland said that in those cases where the douche was contraindicated, its employment was not attended by the dangers met with where, according to the readers' views, its use was indicated, because in

[1] See page 446 of this number of the Journal.
[2] See page 447 of this number of the Journal.
[3] Publication reserved.

the former cases the eustachian tubes were closed, but in the latter, in consequence of atrophy, they were patent and fluid could easily enter; thence he never employed the nasal douche.

DR. LANGMAID said he referred to extreme cases where the fetor was great. In the majority of cases of disease of middle ear induced by the douche there was associated stenosis of the nostril.

DR. DE BLOIS said that in many cases the vault of the pharynx alone was affected, and for the treatment of these he preferred the syringe to the spray, for the uvula will get in the way of the latter and too much force is required to clean away the secretion. He teaches the patient to use the syringe, and never the so-called nasal douche. His experience has been that the large follicles are rarely cured.

ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL BENEVOLENT SOCIETY.

THE Annual Meeting of the Council of the above Society was held at four o'clock in the afternoon of Thursday, October 29th, in the Harvard Medical College on Boylston Street, Boston. A number of new members were elected to the Society, and the usual routine of business was transacted.

At the annual meeting of the Society held at half-past four o'clock of the same afternoon and at the same place the following officers were elected for the ensuing year: *President*, Henry W. Williams, M.D.; *Vice-President*, Richard M. Hodges, M.D.; *Treasurer*, Francis Minot, M.D.; *Secretary*, Robert Amory, M. D.; *Trustees*, Joseph Sargent, W. L. Richardson, F. C. Shattuck, B. S. Shaw, James Ayer, B. E. Cotting, William Mack, J. O. Green, Augustine Shurtleff.

The treasurer reported that he had distributed about fourteen hundred dollars to thirteen beneficiaries who were eligible under the rules of the Society. The invested property of the Society amounts to about $22,000 in current value, but under the restrictions in the methods of investment the accruing income is small.

The object of this Society is to aid members of the medical profession, crippled by age or disease, and their families when in need.

The admission fee to new members of the Society is fixed at three dollars, and the assessment for each subsequent year is two dollars, payable at or before the annual meeting. The payment of twenty-five dollars constitutes a membership for life. The payment of fifty dollars or more at one time entitles the donor to be inscribed as a benefactor of the Society. Any member who shall become a benefactor of the Society, or the widow of any such member shall be entitled to receive the interest of the sum, thus given by him (but not the arrears of interest), as an annuity whenever, and as long as his circumstances shall be such as to lead him to claim said annuity.

No annuity shall be granted to any physician or his widow, if they shall be under sixty years of age, except under peculiar circumstances. But annuities once voted shall not be withdrawn, except on account of misconduct in the recipient, or because this assistance is no longer deemed necessary.

No permanent grant shall be made to any party except upon proof of good moral character, and if granted, it may at any time be withdrawn upon proof of intemperance, improvidence, or immorality; it being the intention of this Society to devote its funds to the relief of distress arising from misfortune and not from misconduct. No permanent grant shall be made to a disabled physician who has, if single, $250 a year, or if married, $300 a year to live upon.

The aid of this Society which was incorporated in 1857, shall be granted for the relief of those only who are or have been members of this Society, and their families; and of other members of the medical profession who are or have been inhabitants of the Commonwealth of Massachusetts, their widows and minor children.

Donations to the general fund of this Society have chiefly come from the members of the medical profession, but in some instances sums of money have been devised from the estate of individuals not directly connected with the medical profession. If some of the experiences of the aid which occasional small sums have rendered in many instances were more generally known, the needs of increasing the general fund and its income would most surely meet with favor among benevolent persons.

Recent Literature.

Puerperal Convalescence and the Diseases of the Puerperal Period, by JOSEPH KUCHER, M.D. 12mo, pp. 311. New York: J. H. Vail & Co. 1886.

This book is a valuable addition to obstetric literature. The author writes after four years service as assistant in the Second Obstetric Clinic of the Vienna Lying-in Hospital, with the additional experience of several years in private practice: the book may therefore be accepted as reflecting the teachings of the Vienna school.

Nearly half of the volume is devoted to the consideration of puerperal fever. The theory that this affection is an essential disease is very successfully combated, and the views of Semmelweis, who nearly forty years ago urged that puerperal fever always originated from infection by the absorption of septic material through lesions in the genital canal, receive the most complete elucidation and vindication that we have seen in the English language. The section on the treatment of puerperal fever is, though brief, especially valuable. We do not entirely agree with the author as to details, believing with Garrigues and Richardson in the use of the occlusive pad and the omission of the vaginal douche in the absence of definite indications. But methods of treatment may be safely left to individual opinion and experience if based on a correct understanding of the septic origin of the affection.

Other chapters are devoted to lactation and affections of the breasts and nipples; to albuminuria, eclampsia, phlegmasia alba dolens, mania, and other puerperal diseases. Practitioners will find these chapters of great practical value.

The style of the book is at times brusque and dogmatic; rather that of the advocate than of the calm man of science. Still, the importance of the subject and the apathy of many members of the profession in the proper understanding of the nature and prophylaxis of puerperal fever go far in excusing an incisive method of gaining attention. We congratulate the author on his work.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, NOVEMBER 11, 1886.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

Subscription Terms: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

THOMSEN'S DISEASE.

In a recent monograph Erb[1] has given us an exhaustive account of this curious affection, and has made great additions to our knowledge of the subject. He admits but twenty-three typical cases among those yet reported, two of which came under his own observation and have been previously reported,[2] and a third was reported by Fischer.[3] The disease is hereditary, affects members of the same family, and begins in infancy or as late as puberty. After any period of rest there is stiffness of the muscles and slowness of movement in any attempt at muscular contraction. After persistent effort the stiffness passes off. If the patient is asked to perform a movement he can do so promptly, but the contraction persists from five to thirty seconds, rendering it impossible for him to relax his muscles. These persistent contractions Erb terms myotonic disturbances of motion. There is great muscular hypertrophy, but the muscular strength is not equally increased. Erb noted "fascicular" contractions in the muscles, which he says are distinct from fibrillary contractions. In the case reported by Pitres and Dalledet[4] the facial muscles were affected, so that there was difficulty in speaking. Erb's researches into the mechanical and electrical excitability of nerves and muscles are of the greatest importance, however. In the motor nerves he finds the mechanical excitability somewhat diminished; the faradic excitability normal, though a sudden increase in the current may produce prolonged contraction, lasting four to ten seconds after the current has ceased; galvanic excitability normal, though a succession of shocks may caused prolonged contraction. In the muscles the mechanical excitability is increased, a touch with the finger being enough to excite tonic contraction lasting from five to thirty seconds. The faradic excitability is very marked, sudden increase causing prolonged contractions, but opening contractions are never lasting. Galvanic excitability is increased quantitatively (KaSZ and AnSZ with one-fourth to two milliampères). Qualitatively both poles may act alike, but the anode may be a little more marked. The muscular contractions are slow and tonic, and prolonged. The most characteristic sign is the occurrence of rhythmical wave-like contractions produced by stabile currents when one pole is placed on the muscle, best of all when placed upon its tendinous end. These contractions proceed from the kathode to the anode. For these wave-like contractions, which are typical, Erb proposes the name of myotonic reaction (MyR); the analogue of reaction of degeneration. He considers it typical of Thomsen's disease, and suggests that a tap of a percussion hammer, and a few kathodic closures will be enough to establish a diagnosis. Fischer obtained these reactions, about fifteen to twenty seconds apart, with a current of 15–20 milliampères. Eulenburg and Melchert,[5] in an interesting series of four cases in one family, find somewhat similar electrical changes, but fail to get the myotonic reaction. Erb removed a bit of muscle from one patient and found an enormous hypertrophy of the fibres. Cross-section of the fibres showed a rounded almost circular outline, instead of the normal polygonal shape. There was an increase of the interstitial tissue and of the nuclei of the sarcolemma. Fischer found the contour of the bundles uneven and tumefied, due possibly to excision. The transverse striation, too, was not well marked. In Fischer's case Erb found also vacuolization of the individual fibres. Erb is not yet willing to affirm or deny that the disease is a tropho-neurosis. Careful post-mortem examinations of the nervous system are still wanting.

RECENT METHODS OF TREATING HÆMORRHOIDS.

Internal hæmorrhoids demand more frequent surgical interference than any other variety of this common affection. Situated completely within the rectum, between the external and internal sphincters,—rarely above the latter,—they may be divided into those which are soft, elastic, highly vascular, erectile, and easily engorged, and those in which the tumors, produced by the extravasation of blood into the adjacent tissue and its subsequent coagulation and fibrinisation, are hard and indurated. The powerful contraction of the sphincter muscles upon such tumors, provokes their protrusion: they often become strangulated, and great pain results if operative measures are not adopted. The dilatation of the anal sphincters, while affording great temporary relief and sometimes even more than this, by removing the cause of the strangulation, does not, however, cure the disease.

The modern and successful treatment of hæmorrhoids requires the adoption of measures which shall

accomplish their cure in a short time, with little or no pain, and ensure the patient against a return of his disease. Of the methods now in vogue for the radical cure, two, namely, the injection of certain agents — notably carbolic acid — and the use of the clamp and cautery are assuming great prominence.

The substances which have been, and still are, employed for the injection of internal hæmorrhoids contain,— as an essential ingredient of the solution introduced,— perchloride of iron, ergot, chloral, alcohol, or carbolic acid. The last named is, at present, generally chosen, and in its selection the object aimed at, and claimed to be most frequently obtained, is a solidification of the hæmorrhoidal tumor without attendant sloughing.

By the cautious use of carbolized injections, a cure can, unquestionably, be brought about, but a pile which has thus lost a portion of its vascular supply, though it may consequently become so small and indurated that it neither bleeds nor protrudes, is not as radically cured as one which has been actually and literally removed. The surgeon cannot be sure it will not return.

In the use of carbolic-acid injections, there is, unfortunately, no rule as to the strength or quantity which can be used with impunity in every case. A weak solution will produce a slough in one case, while a stronger solution used in another will not. As the amount of suffering, as well as the length of treatment, is dependent upon the occurrence or non-occurrence of this accident, which certainly is not infrequent, it must still be regarded as an open question whether the method by injection is the beneficial, safe, and certain remedy which it has been represented to be. "Each injection is a surgical operation, and may cause greater pain and longer confinement by its effect upon a single hæmorrhoid than the clamp and cautery will entail" (Kelsey) in effecting the radical destruction of half a dozen. It is practically impossible to form any opinion of the time necessary for a cure, or the amount of pain which the patient will have to endure.

The most satisfactory method yet devised for effecting a complete and radical cure of internal hæmorrhoids, and the one generally adopted, is by the clamp and cautery. It has none of the disadvantages arising from the method by injection. The pain is not greater, the constitutional disturbances are as slight, and the length of possible confinement is likely to be much less. The clamp and cautery do with certainty at a single operation that which it takes many injections to accomplish. When sloughing takes place as a sequence of the latter, a similar loss of tissue results as from the use of the clamp and cautery, and by a process not so rapid or exact in its limitations. It is a rule, in the use of the clamp, to apply it to the mass in a line radiating from the arms, and not to grasp too much at a time. By so doing, injury to the sphincter muscle is less liable to happen, and the danger of undue cicatricial contraction is diminished. By the injection method such details cannot be so accurately limited.

For these important reasons, if for no others, it would seem that the treatment of hæmorrhoids by injection has not yet reached a perfection which entitles it to implicit confidence. Simplicity of method — emphasized by the halo of special virtues once attributed to carbolic acid — and aided, probably, in some degree by mystery and charlatanry, promised more from its adoption than subsequent experience has justified.

THE TREATMENT OF CHOREA BY CIMICIFUGA.

ACCORDING to Stillé, Physick of Pennsylvania was the first to prescribe the black snake root in chorea. This was as early as 1821. Cimicifuga racemosa was again brought to the notice of the profession as a remedy for chorea, by Dr. Jesse Young, in the *American Journal of Medical Sciences*, September, 1832. Dr. Young prescribed the powdered root in teaspoonful doses three times a day. It was subsequently recommended by Lindsley, Kirkbride, and Eberle.

Stillé, who considers the utility of cimicifuga in chorea as unquestionable, in summing up his observations on the remedy, remarks that "the cases most adapted for its use are those in which the nervous derangement is independent of any definite disease in other parts of the body. It must be used in doses of sufficient strength to develop its specific effects, particularly vertigo and confusion of sight."

Dr. Hiram Corson, a veteran Pennsylvania physician, has again called attention in the *Medical and Surgical Reporter*, to the remedial virtues of cimicifuga in chorea. He affirms that he has used cimicifuga racemosa in every case which has come to him in more than fifty years, "and always successfully in a brief time." He recommends the fluid extract of the dried root in teaspoonful doses after each meal, and a fourth dose at bedtime. Several cases reported by Dr. Corson were all speedily alleviated by the cimicifuga, and in one or two instances the duration of the disease would seem to have been materially abridged.

Dr. Corson is persuaded that none of the other remedies in general use for chorea (not excepting arsenic), have half the value of the black snake-root. Its effect is, he thinks, that of a "quieter of the general nervous system," and he has found it in half teaspoonful doses of the fluid extract a charming remedy for insomnia.

Ringer and Phillips regard cimicifuga as an excellent tonic of the nervous system, and especially suitable for cases characterized by failure of coördination.

— The cause of death of the late Professor Panum, the distinguished Danish physiologist, is said to have been thrombosis of the coronary artery, with consequent fatty degeneration, softening, and finally, rupture of the ventricular wall. He died at the age of sixty-three.

THE TWO HUNDRED AND FIFTIETH ANNIVERSARY OF HARVARD COLLEGE.

The seventh of November has come and gone and with it the celebration by Harvard University of the 250th anniversary of the founding of the College by the appropriation for that purpose of four hundred pounds by the colony of Massachusetts Bay. The celebration itself extended over four days; the first of which, Friday, November 5th, was devoted to a reunion of the Alumni of the Law School, for whom their Association had provided an oration, and a good one, delivered by Mr. Justice Oliver Wendell Holmes, Jr., as well as a dinner at which there was some excellent speaking by old alumni and present teachers, of a character calculated to awaken and foster a spirit of enthusiasm and solidarity among the graduates of the school.

The second day was set apart as an undergraduates' day, and the third day, being Sunday, was marked by services in the College Chapel, and devoted to quiet social intercourse among the many alumni, who had already arrived from all parts of the country, and the distinguished strangers from our own country and from beyond seas, who had gathered as representatives of other universities and colleges or to receive the honorary degrees which Harvard distributed with no niggard hand.

Monday, or graduates' day, was devoted to the programme previously announced. The morning was entirely consumed by the exercises in the College Theatre, to which the officers of government and instruction, the invited guests and the alumni marched in procession; at which Hon. James Russell Lowell delivered an oration, and Dr. Oliver Wendell Holmes a poem, which those not fortunate enough to be present, should take pains to read; and where the honorary degrees were conferred. Dr. Leidy, the distinguished anatomist of the University of Pennsylvania, Dr. S. Weir Mitchell, of Philadelphia, and Dr. J. S. Billings, of Washington, received degrees of L.L. D., upon the especial recommendation of the Medical Faculty, and were all three personally present.

The afternoon was occupied by a dinner of the alumni in Memorial Hall. Both of these festivities were honored by the presence of the Chief Executive Magistrate of the United States, President Cleveland, and of Mrs. Cleveland.

The evening brought the celebration to a fitting close by a torchlight procession under the auspices of the students, and by a fine display of fireworks upon the College play-ground.

The whole celebration passed off in the pleasantest and most successful manner possible, leaving behind it precious memories, and doubtless some digestive disturbances, for the bond of friendship was cemented around many tempting tables.

The occasion, apart from its many features and lessons of more general interest, offers one suggestion to the Medical Faculty and Medical School, and that is, the propriety of starting an Association of Medical Alumni. The Medical School is by far the oldest and largest department of the University except the Academic, and yet it had no distinctive celebration of its own existence, nor was it even represented in the students' procession of the closing evening, thus in both respects offering a strange contrast to its younger and weaker sister of the Law.

MEDICAL NOTES.

— The story is again going the rounds of the ingenious physician who traced the cause of a case of lead poisoning to the patient's habit of holding a *lead*-pencil in the mouth.

— In reply to a correspondent asking the best internal finish for a contagious ward in a hospital, the *Sanitary Engineer* answers: "The best finish for walls in such a hospital ward is probably a good sand finish, on which should be placed three coats of paint. This appears to be the least liable to cracks and scaling, and is readily cleansed and disinfected. The best floor is oak or hard-pine, oiled. A painted floor is not satisfactory."

— *Science* speaks of recent experiments with the common tonic, the tincture of the chloride of iron, diluted with water, showing that when thus diluted it acts very injuriously upon the teeth. This is explained by the fact that the peroxide formed in the alcoholic solution is precipitated, when water is present, in such a flocculent form as not to adhere to the surface of the teeth, and consequently, the free hydrochloric acid can act upon the lime-salts of the teeth without let or hindrance. When the tincture is given without water, no action takes place; the peroxide which is then formed is of the anhydrous form, and so compact as to adhere to the teeth, and protect them from the action of the acid. These experiments have resulted in determining that there are three menstrua which can be used as diluents of this tincture, which will produce no injurious effects upon the teeth: they are alcohol in some form, Vichy water, and a simple syrup.

— A story is told by a French paper of Baron von Humboldt, who, during one of his visits to Paris, expressed to his friend, Dr. Blanche, the distinguished authority on matters concerning insanity, a desire to meet one of his patients.

"Nothing easier," said Dr. Blanche. "Come and take dinner with me to-morrow."

Next day Humboldt found himself seated at the dinner-table of the famous alienist, in company with two unknown guests. One of them, who was dressed in black, with white cravat, gold-bowed spectacles, and who had a smooth face and very bald head, sat with great gravity through the entire dinner. He was evidently a gentleman of undoubted manners, but very taciturn. He bowed, ate, and said not a word.

The other guest, on the contrary, wore a great shock of hair brushed wildly into the air; his shabby

blue coat was buttoned askew, his collar was rumpled, and the ends of his crazy necktie floated over his shoulders. He helped himself, ate and chattered at the same time.

Story upon story did this incoherent person pile up. He mixed the past with the present, flew from Swedenborg to Fourier, from Cleopatra to Jenny Lind, from Archimedes to Lamartine, and talked politics and literature in the same breath.

At the dessert Humboldt leaned over and whispered in his host's ear, glancing at the same time at the fantastic personage, whose discourse was still running on.

"I am very much obliged to you. Your maniac has greatly amused me."

"My maniac!" said the doctor, starting back. "Why, that isn't the lunatic! It's the other one.

"What! The one who hasn't said a word?"

"Certainly."

"But who in the world can the man be who has talked in this fashion all the while?"

"That is Balzac, the famous novelist."

BOSTON.

— Dr. J. S. Billings, of the Surgeon-General's office at Washington, is probably the first person to be decorated with an honorary university degree for being a "student and writer in public hygiene, and a medical bibliographer."

— The title of Doctor was invented in the twelfth century, at the first establishment of the universities. William Gordeina was the first person upon whom the title of Doctor of Medicine was bestowed. He received it from the College of Asti, in 1329. — *Medical Library.*

— An informal dinner was given at the Hotel Victoria, Sunday evening, November 9th, the anniversary day of the founding of Harvard College, to the three gentlemen recommended by the medical faculty for the degree of LL.D. Drs. Leidy and S. Weir Mitchell, of Philadelphia; Dr. Billings, of Washington; President Gilman, of Johns Hopkins University; Prof. E. S. Morse, of Salem, were guests of fourteen gentlemen graduates of the College and the Medical School. The occasion was quite informal, without speeches, and proved very enjoyable.

NEW YORK.

— Dr. Julius F. Miner died at his home in Buffalo, November 5th, aged sixty-three years. He was distinguished in the profession and for many years ranked as one of the ablest surgeons in Western New York. He was born in Peru, Mass., graduated at the Albany Medical School, in 1847, and settled in Buffalo in 1855. He was for several years Professor of Clinical Surgery in the Buffalo Medical College, and also editor of the *Buffalo Medical and Surgical Journal.*

— At a meeting of the Board of Education held November 3d, a letter (which was referred to the Committee on Course of Study), was received from Miss Cattell, General Secretary of the Industrial Educational Association, in which she said that the association was desirous of affording the board an opportunity of practically testing certain branches of manual training, and offered during the current school year, free of expense, to such children as could be sent to the Association's building, instruction in industrial drawing and clay modelling for boys and girls, simple carpentering and the use of tools for boys, and sewing, cooking, and domestic economy for girls. A course of free lectures on industrial education was also offered to the teachers.

— At a meeting of the Board of Estimate and Apportionment, held October 26th, Col. Emmons Clark, Secretary of the Board of Health, explained the estimates of that department of the City Government for the year 1887. The sum of $420,268 was asked for, as against $319,000 appropriated for 1886. The amount allowed for 1887, however, was only $272,000, and the salary account was cut down from $211,728 to $170,000, of which the sum of $20,000 is to be devoted to the payment of the Sanitary Corps. President Coleman, of the Department of Taxes and Assessments, said that under the present management (General Shaler still being the President), it seemed to him that in the Health Department, the men who did the most work received the least pay. He had known many valuable men to be discharged, and useless ones kept in their places, and did not believe it advisable that a larger appropriation should be made until there was a change in the present organization of the Board.

Miscellany.

DR. CHARLES D. HOMANS.

AT a meeting held October 25, 1886, the Boston Society for Medical Improvement, desiring to attest its great regard for its late President, Dr. C. D. Homans, unanimously voted to make the following entry in its records:

"In common with a large number of medical and charitable organizations this Society laments the death of its late associate, Charles Dudley Homans. He was one of its oldest still-active members, and his interest in its meetings never failed. For many years he filled the responsible position of Recording Secretary. Under its more recent method of organization he held the office of President; and as one of the Society's Presidential Committee his excellent and reliable judgment was always faithfully at its service.

"Loyalty to his profession and to his convictions, — never to anything which was unworthy, — unswerving rectitude, unostentatious charity — for the faults as well as for the straits of his fellow-men,— ability and attainments, quick business perception, methodical ways, kindly disposition and manners, and a genial sense of humor, won the respect and favor which placed him in many high positions of honor, of trust, and of medical prominence.

"Doctor Homans died, as he would have wished, with his enthusiasm as keen, his mind as quick and tenacious, as in his best days of health, with all the calmness of one conscious of a well-spent life, and with the affection, the gratitude, and the respect of a large circle of friends, patients, and acquaintances which his personal attributes, and his social and official positions had gathered about him."

C. M. Green, *Secretary pro tempore.*

HYSTERICAL APOPLEXY.

At the meeting of the Société des Hôpitaux, August 13th, (*Medical News*, October 2d, and *Gazette Hebdomadaire*, No. 34), Debove communicated the facts of an extraordinary case of hysterical apoplexy in the male. The patient, a man aged thirty-one, formerly quartermaster in the marines, suddenly lost consciousness and remained insensible for twelve hours; but without convulsions and without involuntary evacuations. For two hours there was complete paralysis of the left side, which gradually disappeared, so that in the morning, on admission to the hospital, there was only an enfeeblement with hemianæsthesia. There was no history of any previous malady, and the patient was a vigorous man, but of an emotional temperament. The diagnosis of a hysterical condition was based on the character of the anæsthesia and its cure by suitable agents. The insensibility involved the skin, mucous membranes, muscles, and organs of sense of the left side. There was limitation of the field of vision, lack of perception of violet color, and monocular polyopia. The application of a magnet caused the return of sensibility in the left arm, and at the same time a disappearance of sensation in the corresponding right limb. It required several days' application of the magnet to restore completely the sensibility of the left side. The motor paralysis followed the anæsthesia in its transference from one side to the other, and disappeared with the restoration of sensibility. Only a hysterical condition could present such features, and be modified and cured by the application of magnets.

PHARYNGEAL AND LARYNGEAL NYSTAGMUS.

In a recent issue of the *Lancet*, were published some notes, in the form of a letter, on rapid rhythmic contractions of the pharyngeal and laryngeal muscles, associated with rapid rhythmic contractions of the ocular muscles, in a case of cerebellar tumor in a girl aged twelve years. Commenting editorially upon the case, our contemporary remarks that the importance of this nystagmus of the pharyngeal and laryngeal muscles lies partly in the interest attaching to the phenomenon, and partly in its suggestiveness. In the case in question, great attention was paid to the state of the rest of the nerves of the body, but nothing in the same nature as nystagmus of any other muscle was observed; nor, so far as known, was there any rhythmical recurrence of sensation in any sensory district. The rate of the rhythm in the pharynx and larynx was perfectly synchronous with the rate of action of the muscles of the eyeball. The ocular nystagmus was of a mixed vertical and horizontal description. It is hardly likely that the symptom which Dr. H. R. Spencer discovered in this case of cerebellar tumor is of common occurrence either in tumors of the brain or in any other disease of the central or peripheral nervous system, but its present recognition will doubtless stimulate observation, and may lead to a still further extension of knowledge. The symptom is a genuine one, and evidently not dependent on a combination of conditions whose balance is easily upset, for the nystagmus has been in constant active operation for at least two months. The rate of the pharyngo-laryngeal contractions, like the synchronous nystagmus of the eyeball, is 180 per minute. It is worth while remembering the circumstance that the muscles which are the seat of the rapid nystagmus in this case are sometimes employed volitionally, and at other times automatically or reflexly. Another feature of the case to which Dr. Spencer alludes is the rate of the pulse, which is unaccountably frequent, being 160 per minute. It may be that this is related in some way to the action of the pharyngo-laryngeal muscles, whose motor fibres in the vagus are derived, in part, at least, from the spinal accessory nucleus, which is also believed to preside over the rate of action of the heart.

INTER-STATE NOTIFICATION IN INFECTIOUS AND CONTAGIOUS DISEASES.

The following resolutions, presented by the National Conference of State Boards of Health, were adopted by the American Public Health Association at Toronto, October 8th, 1886:

Whereas, It is necessary, for the protection and preservation of the public health, that prompt information should be given of the existence of cholera, yellow fever, and small-pox, be it

(1) *Resolved*, That it is the sense of the National Conference of State Boards of Health that it is the duty of each State, provincial, and local Board of Health, in any locality in which said diseases may, at any time, occur, to furnish immediately information of the existence of such disease to Boards of Health of neighboring and provincial States, and to the local Board in such States as have no State Board.

(2) *Resolved*, That, upon rumor or report of the existence of pestilential disease, and positive, definite information thereon not being obtainable from the proper health authorities, this Conference recommends that the health officials of one State shall be privileged and justified to go into another State for the purpose of investigating and establishing the truth or falsity of such reports.

(3) *Resolved*, That whenever practicable, the investigations made under the preceding section shall be done with the coöperation of the State or local health authorities.

(4) *Resolved*, That any case which presents symptoms seriously suspicious of one of the aforenamed diseases shall be treated as suspicious and reported, as provided for in cases announced as actual.

(5) *Resolved*, That any case respecting which reputable and experienced physicians disagree as to whether the disease is or is not pestilential, shall be reported as suspicious.

(6) *Resolved*, That any case respecting which efforts are made to conceal its existence, full history and true nature, shall be deemed suspicious and so acted upon.

(7) *Resolved*, That, in accordance with the provisions of the foregoing resolutions, the Boards of Health of the United States and Canada represented at this Conference, do pledge themselves to an interchange of information, as herein provided.

In addition to the resolutions presented by the National Conference of State Boards of Health and adopted by the American Public Health Association, the following from the Advisory Council of the Association were also adopted:

Whereas, it is necessary for the protection and preservation of the public health that prompt information should be published of the existence of cholera, yellow fever and small-pox:

(1) *Resolved*, That the American Public Health Association believes it to be the duty of each State and provincial Board of Health within whose jurisdiction one of these diseases shall appear, to give immediately notice of the existence of the same to neighboring State and provincial Boards of Health, and to the Boards of towns and cities in neighboring States and provinces which have no central Board. In such States and provinces this duty of notification lies upon the local Boards.

(2) *Resolved*, That it is the sense of this Association that whenever rumors of the existence of pestilential disease in a State or province prevail, and, upon application to the health authorities of said State or province, information respecting the truth of the rumor is refused, the health officials of another State or province are justified in entering the before-mentioned State or province for the purpose of investigating and establishing the truth or falsity of such rumor. In conducting the investigation, every reasonable effort should be made to coöperate with the health authorities of the locality.

(3) *Resolved*, That a case which so nearly resembles one of the specified diseases as to raise a reasonable suspicion of its character, or a case in which concealment is attempted, ought to be reported as a suspected case, in the same manner as if the diagnosis was certain.

IRVING A. WATSON,
Secretary American Public Health Association.

AS OTHERS SEE US.

AN entertaining writer in *London Truth* discourses about the "Physician Himself" from the lay point of view. He says: "The easy-going general practitioner, whether in town or country, but especially in the country, has always appeared to me to have a delightful time of it. An income of some £500 to £700 a year, plenty of moving about, plenty of intercourse with all sorts and conditions of men, and the satisfaction of doing a certain amount of good, and (all things considered) not much mischief, and being paid for both — these are the charms of country doctoring. I confess, I like doctors. They are, for the most part, chatty, pleasant, tolerant men, easy to get on with. The fact is, it is their business to make themselves agreeable, and they get into the habit of being so, even with people who are not, and have no intention of becoming their patients.

Of course, now and then a doctor may find it pay to go in for being habitually rude, and a curmudgeon. Some people — women, I think, more frequently than men — rather like a bear for a doctor. But there is this to be remembered about bearishness — it wants some sort of a reputation to back it. "Rough and Ready" are nags that sometimes go well enough in the medical tandem. But Ready must always go first. A doctor must show himself expert in his business before he sets up to be impertinent out of it. Nobody will put up with impertinence in a young man just starting, and with his spurs yet to win — nobody, that is to say, except the very poor. The very poor and ignorant, I think, like their doctor to be unpleasant, just as they like the medicine to be nasty, and do not believe in it unless it is hard to swallow. When the draught is so horrible that it seems to curdle the soul, then only do they conceive that it "is taking hold," as they say, and will do them good. But although the poor may like the physic to be bitter, and the doctor domineering and rough, these are not the tastes, as a general rule, of the more profitable class of patient. Accordingly, the doctor who means to get on makes it his business to be bland himself, and sees that his prescriptions are as little offensive as the combined resources of chemistry and confectionery will allow.

A doctor may very easily make a fair reputation and a good deal of money without much knowledge of medicine; for this reason, that the science of medicine is a closed book to the vulgar. When a man dies, none of the friends (unless there chance to be a coroner's inquest) know in the least degree what killed him. And if you call in some great medical gun at the last moment, the great medical gun is sure (indeed, I believe by the etiquette of the profession he is bound) to tell you that your doctor has "treated the case most judiciously." On the other hand, when a sick man gets well, no one knows what cured him, and the doctor — who was, perhaps, on the wrong track throughout — gets all the credit. Thus, the best — indeed, almost the only — way in which a doctor can convince his patients that he is wise and knowing in his profession is by showing them that he is a clever and well-informed man out of his profession. Of his science as a doctor they are not in a position to judge; but, if he talks sensibly about subjects which they do understand — stocks and shares, and pictures, and last night's debate in Parliament, and has fair luck with his cases — then his patients will trust and swear by him. I remember one very sad illustration of the injury which a doctor does himself who drops behind in his general information. A friend of mine who had married a wife from the county Westmeath (in those days a very "disturbed" district) came home one afternoon from the stock exchange and found the lady in a terrible state of excitement, piling the fire with pill boxes, and throwing "the mixture as before" out of the window. On investigation, it turned out that the doctor had called, and in the course of conversation had innocently and casually inquired: "What is this habeas corpus, can you tell me, Mrs. Blank, which they talk of suspending in Ireland?" To a lady who had grown up from childhood with the habeas corpus perpetually suspended over her like a drawn sword, the ignorance thus displayed was too shocking. Not a drop of that man's medicines, she declared vehemently, should ever pour down the throats of her children. This shows, I think, that the sensible doctor will do well to look into a book occasionally, and to read the morning papers — but, of course, not the leading articles. This is a punishment reserved exclusively for the editor.

Correspondence.

ABORTIVE TREATMENT OF FELONS.

AMHERST, October 30th, 1886.

MR. EDITOR, — The abortive treatment of felons by the use of collodion has been called for.

In the JOURNAL for March 31, 1881, was a valuable article by Dr. A. N. Blodgett, upon the treatment of strains and sprains by *contractile* collodion, which suggested to me its use for the purpose of aborting felons.

I have used it with success, first upon my own finger in 1881, and afterwards in several other similar cases.

The collodion probably acts by forcing the excess of blood out of the finger and preventing its return, as does the wet rag of Dr. E. T. Williams and the egg-skin treatment of our grandmothers.

It was the remembrance of the latter that led me to try the collodion. Five or six coatings should be applied half way round the finger, and the application is to be repeated whenever the film of collodion breaks or begins to peel off; if applied entirely around the finger the contraction will cause unbearable pain.

I have used the contractile collodion with success in effusions of the knee, in œdema of the hand after fracture of the arm, and in the protrusion of the umbilicus in infants.

I have also used it to hasten the absorption of extravasated blood, especially upon the face and eyelids, after injuries. Very respectfully,

D. B. N. FISH, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 30, 1886.

Deaths reported 1,949: under five years of age 770: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 460, consumption 245, lung diseases 287, diphtheria and croup 202, diarrhœal diseases 85, typhoid fever 55, malarial fevers 34, measles 27, whooping-cough 24, scarlet fever 23, cerebro-spinal meningitis six, erysipelas two (small-pox (Brooklyn) one. From malarial fevers, New York 15, Brooklyn seven. Baltimore six, Chicago four, Charleston one. From measles, New York 19, Cincinnati and Pittsburgh three each, Chicago and Nashville one each From whooping-cough, New York eight, Cincinnati, four, Baltimore and Nashville three each, Brooklyn and Pittsburgh two each, Lowell and Fitchburg one each. From scarlet fever, Brooklyn seven, New York six, Pittsburgh three, Chicago and Cincinnati two each, Boston, Lowell and Fall River, one each. From cerebro-spinal meningitis, New York three, Chicago two, Pittsburgh one. From erysipelas, Chicago and Boston one each. From puerperal fever, Pittsburgh one.

In the 24 cities and greater towns of Massachusetts, with a population of 1,067,629 (population of the State 1,941,465), the total death-rate for the week was 18.07 against 20.23 and 17.41 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,033,817, for the week ending October 16th the death-rate was 18.9. Deaths reported 3,287: infants under one year of age 999; acute diseases of the respiratory organs (London) 223, diarrhœal diseases 271, fever 79, scarlet fever 75, measles 51, diphtheria 34, whooping-cough 30

The death-rates ranged from 13.9 in Bristol to 34.5 in Preston; Birmingham 20.1; Blackburn 27.3; Brighton 16.6; Hull 25.9; Leeds 24.3; Leicester 19.8; Liverpool 23.8; London 16.0; Manchester 24.5; Newcastle-on-Tyne 23.5; Nottingham 22.3; Sheffield 18.1; Sunderland 19.2.

In Edinburgh 15.2; Glasgow 23.9; Dublin 22.5.

For the week ending October 16th, in the Swiss towns, there were 34 deaths from diarrhœal diseases, consumption 22, lung diseases nine, typhoid fever three, diphtheria and croup three, whooping-cough and erysipelas each one.

The death-rates were: at Zurich 3.8; Geneva 10.1; Basle 14.1; Berne 16.0.

The meteorological record for the week ending October 30, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps: —

Week ending Saturday, Oct. 30, 1886.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 30, 1886, TO NOVEMBER 5, 1886.

CLEMENTS, B. A., major and surgeon. Died November 1, 1886, at Fort Leavenworth, Kans.

MIDDLETON, J. V. D., major and surgeon. Ordered from Department of Missouri to David's Island, New York Harbor.

WOODHULL, A. A., major and surgeon. Ordered from David's Island, New York Harbor, to Department of Missouri.

WILLIAMS, J. W., major and surgeon. Ordered from Department of Colorado to Department East.

CORSON, J. K., captain and assistant surgeon. Ordered from Jefferson Barracks, Mo., to Department of Colorado, upon expiration of present leave of absence.

TURRILL, H. S., captain and assistant surgeon. Ordered from Department Platte to Department of Colorado.

MUNDAY, BENJ., first lieutenant and assistant surgeon. Ordered from Department of Colorado to Jefferson Barracks, Mo., S. O. 252, A. G. O., October 29, 1886.

OWEN, WM. O., JR., first lieutenant and assistant surgeon. Relieved from duty at Fort Schuyler, New York Harbor, and ordered for duty as post surgeon, Plattsburg Barracks, N.Y. S. O. 170, Division of the Atlantic, October 29, 1886.

EDIE, GUY L., first lieutenant and assistant surgeon. Ordered from Fort McIntosh, Tex., to Post of San Antonio, Tex. S. O. 152, Department of Texas, October 27, 1886.

HARRIS, H. S. T., first lieutenant and assistant surgeon. Ordered from Post of San Antonio, Tex., to Fort Clark, Tex. S. O. 152, Department of Texas, October 27, 1886.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING NOVEMBER 6, 1886.

NEILSON, J. L., surgeon. Ordered to the Receiving Ship "New Hampshire."

DRENNAN, M. C., surgeon. Detached from Receiving Ship "New Hampshire" and granted one years' leave.

SOCIETY NOTICES.

SUFFOLK DISTRICT MEDICAL SOCIETY. OBSTETRICAL AND GYNÆCOLOGICAL SECTION. — There will be a meeting of this Section at the large Medical Library Room, 19 Boylston Place, on Wednesday evening, November 17th, at 7.45 o'clock. Communications: Dr. W. E. Boardman, "A Case of Labor complicated by Fibroids, with some Remarks." Dr. E. W. Cushing, "On Erosions of the Os Uteri, with Demonstration by Stereopticon of Photographs from Life and Micro-Photographs." Dr. Cushing will show four ovarian tumors removed in the last two months, and a curiously large mass of glands scraped from the uterus. Gentlemen are especially urged to prepare papers for the Section and to notify the Secretary of their willingness so to do, and are requested to exhibit specimens or apparatus at any of the meetings. Refreshments after the meeting.

JAMES R. CHADWICK, M.D., *Chairman.*
ROBERT B. DIXON, M.D., *Secretary.*

APPOINTMENT.

Dr. T. M. Rotch was appointed during the summer a visiting physician at the Boston City Hospital.

DEATH.

Died in Salem, Mass., November 4, 1886, Frank Albert Durgin, M.D., M.M.S.S., aged thirty-one years.

Lecture.

ON DIET IN DIABETES.

A LECTURE ON ALIMENTARY THERAPEUTICS.

BY PROF. DUJARDIN-BEAUMETZ, M.D.,
Physician to the Cochin Hospital, etc., Paris, France.

In the last lecture we had under consideration the hygienic treatment of gout and gravel. I propose to devote the present lecture to the subject of diet in diabetes. For the diabetic, diet constitutes the sovereign curative means, it being only by the application of rigid dietetic regulations, that we can, in a great number of cases, cause the disappearance of sugar from the urine; hence we need to spend considerable time on this subject. But in order to establish on scientific basis the alimentary regimen of diabetes, it is necessary that I should briefly sum up the data in our possession respecting the pathogeny of this affection.

Till the discovery of glycogenic function of the liver, and the immortal labors of Claude Bernard, the etiology of diabetes was involved in great obscurity. Claude Bernard gave us our first insight into the causes of this disease, and now, for almost forty years his pathogenetic doctrine, despite the most searching criticism, still remains master of the field.

Bernard showed us this capital fact that in the physiological state in all mammals and in man sugar is found in the blood. This is what he calls *physiological glycæmia.* When the figure of glucose in the blood exceeds certain limits — 3 per 1000, it passes out in the urine and determines glycosuria.

Whence comes this physiological sugar? It has two sources: either it results from the food, or it is produced by the liver. In previous lectures, I have shown you that amylaceous substances when modified by the salivary diastase, and by a special ferment of the pancreas, amylapsin, enter the economy in the state of glucose, and that the sugars, inverted by the intestinal juice, also reach the circulation in the state of glucose. We have here a constant source of glucose furnished to the blood. When the quantity of these amylaceous or saccharine aliments is too great, all the glucose formed is not burned in the economy, the figure of physiological glycæmia is exceeded, and there results a temporary glycosuria, known under the name of *alimentary glycosuria.*

The other source of sugar is the liver. In 1848, Claude Bernard first called attention to a new function of the liver, and since then, on many different occasions, he has elucidated his important discovery and its practical consequences. The glucose contained in the blood deposits in the liver a substance similar to starch, *glycogen*, which, under the influence of an hepatic ferment, is transformed into glucose; this constitutes the glycogenic function of the liver.

The liver, with respect to physiological glycæmia acts the part of a regulator of this function. When too much glucose is furnished by the food, the liver stores up, under the form of glycogen, the excess which is not utilized. When elements suitable for making sugar are not furnished by the food, it is then that the liver furnishes it to the blood, so as always to maintain an equal quantity of glucose in the economy. But let some disturbance of a nervous order come in to modify the cellular exchanges in the liver, then this organ makes more sugar than the normal proportion, and this excess enters the blood; the figure of 3 per 1000 is exceeded, and glycosuria results; in a word, hyper-glycogenesis produces hyper-glycæmia. Claude Bernard even realized experimentally this hyper-glycogenesis by wounding in animals certain parts of the fourth ventricle.

Such were the bases on which Bernard established the pathogeny of diabetes, and, as I told you in the beginning, physiologists have more or less modified this pathogenic doctrine, but without overthrowing it.

Thus it is that Pavy has denied the transformation of glycogen into sugar, is a physiological fact. According to him, (as also to Schiff, Meisner, Tschsrinow and Seegen), this is a fact of pathological order; the glycogen accumulated by the liver, serving in the normal state, to make, not sugar, but fat. Bouchard, Jaccoud, Lecorché, and Esbach have also completed the doctrine of Claude Bernard.

Lecorché, to whom, by the way, we are indebted for an excellent treatise on diabetes, assigns an important part to the increased secretion of urea which almost always accompanies glycosuria. According to him, the liver in diabetic persons under an influence which escapes us, undergoes an exaggeration of its glycogenic functions. It now makes sugar, not only out of amylaceous and saccharine matters, but also from all sorts of albuminoid substances, and even from the muscles of the diabetic patients, transforming the albuminoid into glycogen and urea.

Jaccoud adopts the same view; he divides diabetes into two stages. At the onset, there is only glycosuria; then at a more advanced period there is azoturia and glycosuria; this is what he describes under the name of *azotized diabetes.*

On the other hand, Bouchard, returning to the notions of Dechambre, Reynoso, and Mialhe, who considered diabetes as due to insufficient utilization of the sugar produced, labors to show that hyper-glycæmia results from the fact that the organism does not accumulate the sugar incessantly furnished by the liver. He points out the fact that the liver produces daily about two kilogrammes of sugar, of which seven hundred and ninety-eight grammes only are burned by the respiration. The twelve hundred grammes remaining ought to be utilized by our tissues. Let some circumstance intervene to modify the molecular exchanges, these twelve hundred grammes of sugar will not be employed by nutrition, and glycosuria will appear. Hence Bouchard refers diabetes to the general troubles of nutrition, which he has described under the name of *retarded nutrition.*

Lastly, in a very original and quite recent work,[1] Esbach has modified the theory of Claude Bernard. According to him, the diabetized liver produces a particular kind of glucose which loses the property of being destructible. He opposes this non-destructible sugar, which he calls *diabetose*, to the sugar furnished by the liver in the physiological state, to which he gives the name of *assimilable glucose.*

As you see, gentlemen, the new theories of the pathogeny of diabetes have but little modified Claude Bernard's doctrine. Basing ourselves on these data, we can establish on a scientific foundation the alimentary hygiene of the diabetic.

This hygienic treatment must fulfil the two following great conditions: On the one hand, it must reduce to their minimum foods, which introduced into the

[1] Printed from advance sheets.

economy may furnish glucose, and on the other, energize as much as possible the combustion of the glucose formed in the economy.

But before entering into the details of this treatment, I must say a few words about the prognosis of diabetes. This prognosis is entirely based on the effects of an antidiabetic regimen rigorously followed. Never forget, in fact, that it is not the quantity of sugar voided daily in the urine which constitutes the gravity of the prognosis in diabetes; it is the greater or less facility with which the sugar disappears under the influence of diet.

In this respect we meet with three forms of diabetes which I have called *mild diabetes.*

DIABETES OF MEDIUM INTENSITY, AND GRAVE DIABETES.

In his interesting studies on diet in glycosuria, Duhomme has given to these three forms the names of simple uroglycosis, mixed uroglycosis, and complex uroglycosis.[2]

In mild diabetes, by the simple fact of an appropriate alimentary treatment the sugar disappears rapidly and completely from the urine, whatever may have been the quantity previously voided. I have for my part seen great numbers of diabetics who were losing daily from four to eight ounces of sugar, and who, after eight days of treatment according to Bouchardat, excreted none at all. It should be understood that in these patients the least infraction of diebetic rules brought back the glycosuria; these are the mild cases.

In diabetes of medium intensity, you will diminish considerably by rigid dieting the quantity of sugar voided, without, however, causing it to disappear entirely, and there will always be an amount in the urine varying between ten and twenty grammes. Bouchardat calls these cases "*petits diabetiques*, that is, *little diabetics.* Often certain medicines will cause, in these patients, complete disappearance of the sugar.

Lastly, in the grave forms of diabetes, whatever may be the rigorousness of your dietetic rules, the quantity of sugar eliminated is always considerable, and when the food which these persons eat does not contain the elements proper for making sugar, the substance of their muscles is transformed into glycogen and urea. These are the lean diabetics, the azoturic diabetics all condemned to a sure and speedy death.

As you see, the prognosis depends entirely on the results of diabetic treatment. What, then, should be the diet in diabetes? Exclusive regimens, have been proposed, and mixed regimens. The former are two in number; the adipo-carneous, and the milk regimen. Cantani has the most earnestly advocated a rigorous flesh and fat diet treatment; he allows nothing but meat and fat. The fats are designed to take the place of the carbo-hydrates, of which he deprives his patients entirely. The patient can eat no vegetable, no starchy food of any kind, and no eggs. Salt is permitted, as well as salt meats and salt fish. To this treatment, Cantani conjoins the usage of lactic acid. This is administered under two forms: as pure lactic acid, in the dose of fifteen to thirty grains in four ounces of water, and half an ounce of fennel water, three times a day, or in the form of an alkaline lactate, eight grains of bicarbonate of soda being added to four ounces of the lactic acid solution above mentioned. This dose of lactate of soda is repeated every hour or every two hours. Lastly, at the end of a certain time, fifteen or twenty days, if the sugar is not all gone from the urine, Cantani orders a twenty-four hour's fast.

Cantani's treatment has had few partisans, and this for several reasons. First, by reason of the repugnance of patients to eating nothing but meat and fat, a repugnance such that many of these prefer to remain diabetic rather than persevere with such a diet. Moreover, an exclusively meat diet notably augments the azoturia of these patients, already predisposed thereto by the fact of their diabetes. Likewise the uric acid gravel with which many diabetics are affected is markedly aggravated under this regimen. In fact, if we may trust Jaemiche, Caplick, Bond, Windl, and Ebstein, the meat diet determines the presence of acetone in the urine and thereby favors acetonæmia in the diabetic.[3] I discard, then, for these reasons the exclusive adipo-carneous regimen.

Donkin, an English physician, was the first to advise an exclusive milk diet in diabetes. This is his method of treatment; he begins with four to six pints of skim-milk a day, and gradually increases to twelve pints. Of these twelve pints, seven or eight only should be taken liquid, the rest is ingested in the state of curds. The milk should be drunk tepid. At the end of a fortnight, according to Donkin, the sugar will have completely disappeared from the urine.[4]

I do not know whether cases of amelioration obtained by this method are numerous; Kultz, who has tried it, affirms that he has derived no good result. For my part I think it a dangerous treatment. Just think of giving to a polydipsic patient six quarts of milk a day! Think of giving him, moreover, a substance which contains a notable quantity of sugar! Such treatment can but aggravate the malady. I have always seen in diabetic patients that were allowed to drink freely of milk a marked augmentation of their glycosuria, and like Bouchardat, I discard milk from the dietary of the diabetic.

We are indebted to Bouchardat for the principle of the mixed alimentary treatment of diabetes, and in formulating these principles in so exact and practical a manner, my venerated master has earned the gratitude of the entire medical profession, for now we are able by diet alone to cause sugar entirely to disappear from the urine in a great many cases, and in all we obtain a marked amelioration.

In order that you may sufficiently grasp the importance of this regimen, I will consider it under three heads: bread, drinks, and foods allowed and forbidden.

Bread is an aliment which may well be called indispensable, so accustomed are we to it from our earliest childhood, and the introduction of gluten bread into the dietary of the diabetic, for which we are indebted to Bouchardat, is one of the most important parts of this alimentary regimen. Many patients, in fact, refuse to eat when bread is not given them, and you should not forget that voluntary or involuntary abstinence is always prejudicial to diabetic patients. Habitually gross eaters, the diabetic have need of a reparative and substantial diet, and when you come to cut off the necessary supplies of food, grave symptoms

[2] Duhomme. On Diet in Glycosuria. (Bull. et Mém. de la Soc. de Thérapeutique, Séances des 23 Nov. 1881, 14 Mars., 1883, 13 Jan. 1886).

on the part of the patient are almost sure to supervene; he grows feeble, emaciates, and becomes a suitable culture soil for bacilli to thrive in. You ought, then, as far as possible, to respect the appetite of diabetic patients, and do nothing to impair it, and this is one of the causes which have led us to abandon the exclusive regimens.

Bread is an alimentary necessity, and you will recognize this fact by ordering gluten bread. But gluten bread is of variable quality, some bakers having more starch, some less in their gluten bread. The French gluten bread, which is dried in slices, contains the least proportion of amylaceous principles. Bouchardat was prone to order Cormier's brand. This kind of bread, however free it may be from starch, and however well it may fill the indications, often fails to satisfy the patient, who is apt to fancy most the bread which contains the least gluten. I am told that the Health Food Company of New York[5] make an excellent flour, which retains well the salts of the wheat, while being comparatively free of the starch.

It is quite a common thing to see diabetic patients, who, despite the augmentation of glucose in their urine, affirm that they have not transgressed their dietitic rules. I have generally found, in the case of such patients, by pressing my inquiries, that they had been substituting for the gluten bread which I had prescribed a preparation like the French rusks (échaudé), which contains considerable starch. This is a great mistake; there is not much difference between this latter product and ordinary baker's bread, the former containing 54.1 per cent. of starch, and the latter 56 per cent.

It has been proposed to replace ordinary bread by almond bread, and this substitution has been especially recommended in Germany. If these almond loaves or cakes constitute a kind of bread that may be taken with safety by the diabetic, they are certainly not very palatable, and in France we make little use of them.

Dannecy, of Bordeaux, has proposed a mixture of bread-crust and meat-powder. Others, taking advantage of the difficulty which most diabetic patients experience in masticating their food, on account of bad teeth or the want of teeth, have advised bread-crust or toasted bread. Esbach, in a late article in the *Bulletin de Thérapeutique* (t. CIV., p. 201), has, however, shown that in equal weights, the crust of bread contains more sugar-producing substance than the crumb, and that it is a mistake to prescribe crust for the diabetic. The following table from Esbach sets this clearly before you:

	Sugar.
100 grammes of crust of ordinary bread produce	76 grammes.
100 " of crumb of ordinary bread produce	52 "
100 " of ordinary gluten bread furnish	18 "
100 " of good potatoes, boiled, give	17 "

I call your attention especially to the statement with reference to potatoes, which seems to me a little exaggerated, if we may trust the analyses furnished by Mayet, who maintains that 100 parts of cooked potatoes (baked, it is true, not boiled) yield only 8.30 of sugar, while 100 parts of gluten bread yield 27 parts.

I cannot too much insist on the utility of potatoes in the diet of diabetic patients who cannot dispense with bread. Of all amylaceous food substances, potatoes contain the least starch, and for that reason, produce the least sugar, and the difference between gluten bread and potatoes is so greatly in favor of the latter, that you will do well, in most cases, to subject your patients to the English regimen, that is, suppressing bread, and substituting baked potatoes.

The subject of drinks is also one of importance, polydipsia being one of the results of this disease. Many victims of diabetes become intemperate, and this happens the more naturally, that they resist better than others the effects of alcoholism. Persuaded that they will find in alcoholic beverages a tonic which they need, they drink their wine pure, or mix brandy with their water. The quantity which they add may be small, it is true, but as the spirituous draught is constantly being repeated, a large amount will have been imbibed by the time the day is done.

In fine, so strong is the temptation to indulge in "bitters" and other liquors under which the diabetic patient labors when walking along the thoroughfares where drinking-saloons abound, that he is in danger of becoming an inveterate tippler. One of my preceptors, the late Chassaignac (I have had three who were diabetic), has often told me that he suffered a veritable Tantalus punishment when going through the public streets, and seeing in full view the liquor saloons and the tipplers inside, and notwithstanding the possession of a strong will, he found himself continually yielding to the propensity to quench his thirst at some of the drinking-booths which he passed.

I believe, then, with Bouchardat, that we should restrict as far as possible the use of alcoholic drinks in glycosuria. The patient should be allowed to drink freely, at his meals, of wine diluted with some alkaline mineral water, but he must not be permitted to drink between meals. If he must have something to quench his thirst, let it be weak tea or coffee, without sugar or milk, or some mild bitter ptisasi, like infusion of chamomile or quassia. I prescribe milk for reasons I have before mentioned.

I come now to foods that are permitted, and those that are forbidden. In order to guide you in the choice of foods proper for the diabetic, and such as should be interdicted, you should always have before your eyes the following table, which shows the proportion of starch or saccharine material in various alimentary substances. I borrow the first of these tables from Dr. Nedats. Table I, gives you the proportion of starch in the principal amylaceous aliments:

	Per Cent.		Per Cent.
Rice	74.10	Wheat Bread	42.70
Corn meal	65.50	Oatmeal	39.10
Wheat flour	63.00	Peas	37.00
Wheat (unground)	59.60	Rye bread	36.25
Rye meal	59.84	Beans	36.00
Millet seed	57.90	Cucumbers	16.60
Buckwheat	50.00	Potatoes	15.50

You can compare this table with the following by Boussingault, the first column showing the per cent. of vegetable, albumen, gluten, legumin and the like; and the second column the per cent. of starch, dextrim, and the like principles.

Round gluten biscuits	44.9	40.2
Gluten cakes	21.3	64.7
Barley bread	18.9	66.6
French rusks	10.9	51.3
Maccaroni	9.5	76.4
Sago	9.1	74.7
Bakers bread of Paris	7.0	56.3
Rice	7.5	76.0
White Beans	26.9	48.8
Lentils	25.0	55.7
Peas	23.8	55.7
Potatoes	2.8	23.2

[5] A reliable chemical examination of the diabetic *biscuits* sold by this Company showed that they contain 74+ per cent. of sugar-forming material, and under the microscope, the field was crowded with starch granules. This percentage of sugar-forming material is even higher than that of ordinary fresh bread, the moisture of which counts for much. Diabetics, or their advisers, had better have all so-called "diabetic foods" carefully examined before using them.

Lastly, Mayet has given in terms of sugar the quantity of starch contained in 100 parts of the following amylaceous substances, and these are his figures:—

	Per Cent.		Per Cent.
Turnips	7.00	Lentils	22.05
Baked potatoes	8.50	Rice cakes	25.00
Boiled rice	8.00	Fresh gluten bread	27.07
Peas	12.00 to 15.00	Vichy Company bread	31.00
Beans	16.00	Ordinary bread	60.00
Carrots	16.00	Wheat meal	70.00
Chestnuts	20.00	Starch	83.00

Stews may be permitted with some limitation, especially such as are fatty, and "bouillon" with poached eggs. Broth made with vegetables, and in particular with onions and cabbages is allowable, as well as "Julienne" soups, but neither turnips nor carrots must enter into their composition. You will also allow broth made with potatoes, to which beets may be added, but you will forbid pea-soup, and bean-porridge, also stews containing dumplings. Custards are also to be prohibited, as also other culinary preparations containing milk.

All kinds of meat are allowed, that is, the flesh of animals, fish, mollusks and crustaceans. Sauces which contain flour are to be interdicted, also those into which milk or cream enters as an ingredient. You will also forbid fish fried in meal.

All kinds of fatty foods are permitted; they may even be eaten very freely in order to furnish to the economy the carbo-hydrates that are necessary. All kinds of amylaceous and saccharine materials are, as before said, to be interdicted, except potatoes, which are even better for the diabetic than gluten bread.

The exclusion of sugar, as I have told you, is absolute, but there are some patients that cannot get along without some sugar; in such cases you can allow them to sweeten their tea, coffee and lemonade with glycerine.

Vegetables are permitted in the regimen of diabetes, and Bouchardat has always insisted on the disadvantages of an exclusively animal diet in this disease. Vegetables are useful because they give variety to the diet of the diabetic, and because they furnish a valuable element, potash, to the economy. Boussingault has, in fact, shown that one kilogramme of the following vegetables contains potash in the proportion here given, the figures indicating grammes:

Cabbage	2.6	Beets	6.8
Chicory	1.7	Potatoes	3.2
Turnips	3.7	Spinach	4.5
Carrots	2.5		

Taking, then, as your guide the foregoing tables, you will order spinach, sorrel, beans, lettuce, cabbage, asparagus, celery, artichokes, dandelions, all the salads, etc. But you will forbid beets, carrots, and turnips, by reason of the sugar which they contain, and you will caution the patient to be chary of onions, leeks, and cooked artichokes. There remains the question of fruits, and in general they ought all to be proscribed. In fact, if you will refer to the analysis of Mayer, and which I place before you, you will see the large quantity of glucose which fruits contain, and with the exception of currants, they ought to be, as a rule, rejected.

PERCENTAGE OF SUGAR IN CERTAIN FRUITS.

Currants	1.50 to 18.00	Figs	10.00
Melons	7.50	Prunes	16.00
Raspberries	8.00 to 10.00	Dried prunes	42.00
Oranges	10.00	Dried figs	71.00
Cherries	10.25	Raisins	79.00
Peaches	10.50		

Such are the indications which will enable you to decide upon the diabetic rules applicable to diabetes. These rules should be followed to the letter, and for a long period, if not during the entire life-time. Often repeated analyses of the urine, will enable you to decide how far the patient may return to his ordinary fare, also to ascertain if your rules are rigorously carried out, the least enfraction of them always producing an increase of the sugar excreted in the urine. Moreover, it will be your duty to point to the patient the great importance of this strict regimen, by which you will be able in a great many cases to clear the urine of sugar, and in all, to obtain a marked amelioration.

But dietetic rules do not alone constitute the hygienic therapeutics of diabetes. We must add varied muscular exercises, to which I shall refer when I come to speak of gymnastics and massage, and which have a large share in the results of the treatment, by enabling us to fulfil the second part of the therapeutic problem which we have to work out, namely, how we may best forward the combustion of glucose existing in excess in the blood.

Original Articles.

A CASE OF UNUSUAL DEFORMITY OF BOTH HIP JOINTS.[1]

BY G. H. MONKS, M.D.

THE patient, F. M., is a young man of sixteen years. He came to me some months ago at the Carney Hospital, complaining of pain and stiffness in both hip joints, from which he stated he had suffered for about two years.

On examination of the hip-joints it soon became evident that some unusual pathological process had been at work. As the patient stands facing you (see Fig. 1), you will notice that he is apparently well nourished, and that his muscles as a rule are well developed. The right side of the pelvis is slightly higher than the left, and the right trochanter projects somewhat more than its fellow. At a point about two and one-half inches below the anterior superior spine of the ilium on the right side is a rounded projection; on the left side is a similar one, but less marked. These projections are both on a lower level than the trochanters. The muscles of the thighs are not well enough developed to be in keeping with the rest of the body. There is knock-knee on both sides, particularly on the left, and both feet are flat.

The eversion of the right foot shows that the thigh on that side is strongly rotated out: the left foot is also somewhat everted.

If the patient be turned to the side (see Fig. 2) the first peculiarity noticed is the flattening and almost complete obliteration of the lumbar curve. The distance between the lower margin of the thorax and the crest of the ilium is considerably shortened, a fact easily appreciated by the touch if not by the sight. The trochanter occupies a position too high up and too far forward to be natural, and this observation has been verified by comparative measurements of the same parts on normal bodies.

The axis of support appears, therefore, to be too far forward, and the back part of the pelvis to be somewhat depressed by the weight of the body resting upon

[1] Read before the Suffolk District Medical Society, October 30, 1886.

it. There is a marked hollow behind the trochanter and the nates are flattened and flabby. The appearance of the left side is much the same as that of the right.

Occasionally the heel of the right foot is slightly raised while the patient rests upon the ball of the toes. In walking, however, this will be more evident.

Fig. 1.

Fig. 2.

Fig. 1 shows that the right side of the pelvis is somewhat higher than the left, and that the right trochanter projects more than its fellow. The dotted lines represent the position of the iliac crests, the great trochanters, and the protrusions in the groin caused presumably by the displaced head of the bone. Note also knock-knee and eversion of foot.

Fig. 2 shows the flattening of the lumbar curve, the position of the great trochanter and the line of the iliac crest; also the depression behind the trochanter. The axis of the femur being farther forward than natural, the weight of the upper part of the body transmitted through the lumbar vertebræ, has depressed the back part of the pelvis and consequently obliterated the lumbar curve.

On looking at the patient from behind (see Fig. 3), the pelvis is here again seen to be tilted up slightly on the right side. The trochanters, particularly the right one, are prominent, and the back in the lumbar region and the nates are flattened so that their surfaces appear to be very nearly in the same vertical plane. (This last deformity is unfortunately not well shown in Fig. 3). The depression behind each trochanter is marked, and is even more so when the patient bends forward.

Now, when the patient lies upon the table, and an attempt is made to manipulate the thighs, it is found that the right hip is so rigidly fixed that it is only with the greatest difficulty that one can detect a movement between the thigh bone and the pelvis. The motion at the left hip joint, on the other hand, is somewhat freer, but that too is decidedly limited. On account of this rigidity the patient finds it impossible to lie down on the floor without assistance, or once there to stand up again. The projection before spoken of on the right side just below the anterior superior spine of the ilium we now find to be due to a rounded bony mass, quite smooth, and this is presumably the head of the bone. When the thigh is moved this mass can be felt, though only by the closest observation, to move with the femur. The presumption that this mass is the head of the femur is strengthened by the fact that a bony ridge of about the size of the femoral neck can be traced from it to the trochanter. The rounded projection on the left side is much easier to examine on account of the comparative mobility of the left hip joint. The bony mass causing the projection moves freely with the femur and is without doubt the head of that bone. The heads of the two bones are then considerably lower than the trochanters, a condition which renders highly probable the assumption that the necks have been the seat of some pathological process by which they have been weakened, thus allowing the heads to be borne down by the weight of the body.

The following are the most important measurements taken on the patient while on the table. From the symphysis pubis to the most prominent part of the right trochanter is eight and one-half inches, to the most prominent part of the left trochanter is only eight inches, thus showing that the right trochanter projects more than the left by a half inch. There is no practical difference in the length of the two limbs, as measured from the anterior superior spine of the ilium to the inner malleolus. The test line of Bryant's triangle proves the right trochanter to be one-fourth inch higher than its fellow. Nelaton's line is difficult to place on account of the tuberosity of the ischium being farther to the front than normal. About one-half inch of the right trochanter is above it, while the tip of the left trochanter just touches it.

Fig. 3.

Showing the tilting up of the pelvis on the right side, and the prominence of both trochanters, particularly of the right one. The flattening of the back in the lumbar region and up the buttocks is not seen so well here as in profile, but the depressions behind the trochanters are well marked.

The gait of the patient is very peculiar. He walks with a sort of waddling motion, the upper part of his body moving from side to side. More singular still is the gait as viewed from the side. If the patient be now carefully watched it will be seen that there is no apparent motion at the right hip-joint whatever, and that when the right limb is used the joints between the lumbar vertebræ have to do the duty of that joint. Just as the patient puts forward the right leg, then, the lumbar region may be seen (in profile) to curve backwards, and when he puts his foot to the ground this backward curve becomes straight once more.

Simultaneously with the bending backwards of the lumbar vertebræ the pelvis seems to fall slightly downwards behind and to rise in front, as though it were rotating around an axis represented by a line from one trochanter to the other. As this rotation progresses a transverse crease forms in the abdominal wall across the umbilicus, but whether this is due to the rising up of the anterior part of the pelvis or to

the sinking down of the thorax, as the patient leans forward to keep his equilibrium, is difficult to say. The left limb, however, appears to swing quite freely from the hip-joint, and there is therefore nothing peculiar in its motion.

In attempting to account for the deformity just described, it is fair to assume that the head of the bone on the right side is not in the acetabulum, but is displaced forwards to a point where a new socket has probably formed about it, and that the condition on the left side is essentially the same, except that the process has not advanced so far.

Now, as the two thigh-bones are displaced forwards, the equilibrium of the pelvis is disturbed. The centre of gravity, instead of falling through these bones, falls behind them, and this means a sinking of the pelvis behind, and a corresponding flattening of the lumbar curve. At the same time, the patient throws the upper part of his body forwards to prevent falling.

The young man's history is briefly this: He was born in Germany, and came to this country with the other members of his family about one year ago. The lad is not very intelligent — a fact which would tend to weaken the value of many points in the history which he gives. The patient declares, and his statement is verified by his mother, that he was always perfectly well until within the last two years; that he could run, jump fences, and climb trees like other boys, and that he had never suffered any injury. No member of his immediate family ever had rheumatism or any trouble in the joints whatsoever.

The patient's first symptoms were pain and stiffness in the right hip, followed, in about three months, by the same in the left hip. These symptoms increased, and to get relief from the pain, he would stand, rather than sit, for, in sitting, flexion of the thighs would cause pain. Even now, he seldom sits in a chair. As the pain continued to increase, the patient took to his bed for five weeks, during which time his condition gradually improved.

When he got about again he would be now better, now worse, and so on, until the time I saw him. The constant use of electricity, probably by its beneficial effect on the muscles, has relieved him considerably. He declares that he is much better, and has been able to take light work.

The history of the case excludes at once the possibility of our having here to do with any form of *traumatism* (such as fracture, dislocation or separation of the epiphysis), or with any disease of the joints *resulting from affections of the nervous system.*

The deformity and the youth of the patient suggest a *congenital dislocation*, which has been overlooked; but a double congenital dislocation forwards must be extremely rare, if, indeed, it ever occurs, and with such a deformity from birth, how could the boy, until within a few years, run and jump fences as well as the other boys.

Dry caries (caries sicca), either with or without diastasis, would have been accompanied by more constitutional disturbance than this case has shown. The patient would have been confined to his bed for months or years, instead of for a few weeks. Moreover, caries could have hardly advanced so far as to cause the deformity noticed here, without suppuration, and there is now, and so far as I can judge, there has never been any sign of pus formation. The conclusion is, therefore, forced upon me that we have here to do with a case of *arthritis deformans.* The remarkable features are that this boy of sixteen years should have the disease at all, and that the process, once established, should advance to such a degree of deformity as we have seen.

The patient suffered in the beginning, and continues to suffer with pain and stiffness in the joints, and this history corresponds exactly with that of arthritis deformans. His family live in a damp cellar in an unhealthy part of the city.

Pathological specimens of the disease show that all sorts of unusual deformities may result, and that partial, or even complete luxations may occur. It is highly probable that, as has already been intimated, the heads and necks of the bones have been so affected by the disease, that the weight of the body has been able to depress the former by the yielding of the latter, and that the anterior rim of the acetabulum, likewise softened, and thus unable to resist the force of the head pressing against it, has gradually given way, and a dislocation, more or less complete, has resulted. That the dislocation is forwards, instead of backwards, is a mystery.

THE PURIFICATION OF DRINKING-WATER BY FILTRATION.[1]

BY PROF. WILLIAM F. SEDGWICK, MASS. INSTITUTE OF TECHNOLOGY BOSTON.

[PROFESSOR SEDGWICK began by explaining that he had been asked to say a few words upon filtration by way of introducing the subject, and also to show the micro-membrane filter exhibited last spring before the Society of Arts by the late Prof. Wm. Ripley Nichols. He proceeded substantially as follows: —]

Drinking-water is seldom or never free from organic matter. A good quality of deep-well water is probably as free as any other from it, and yet Frankland, by the method of biological examination (gelatine plate-cultures), found rarely more than ten microbes in one cubic centimeter of such water. The same quantity of water taken from the Thames at Hampton contained about one thousand microbes.

We shall probably not be far wrong in supposing the same to be true of drinking-waters generally. All contain more or less of organic matter, if not when first taken from the well or spring, certainly before they enter the mouth. Some of this matter is living, in the shape of bacteria, infusoria, diatoms, etc., and some is lifeless, being either dissolved or suspended. The entire quantity, however, in what is ordinarily called wholesome drinking-water — namely, that from springs, wells, rivers, etc. — is a very small percentage of the total volume of liquid. These waters are by no means necessarily to be condemned on that account, but are still to be regarded as perfectly wholesome.

There is, nevertheless, a *possibility* of danger in this organic matter, and hence the water-supply of a community must always be closely watched, and, if necessary, rarely, in times of epidemics, perhaps even abandoned altogether for a while. But this possibility, once recognized and constantly kept in mind, need not cause great anxiety. For example, the "Cochituate" is by no means free from organic matter; on the contrary, it contains abundant micro-organisms; there is

[1] Read before the Section for Clinical Medicine, Pathology, and Hygiene of the Suffolk District Medical Society, October 13, 1886.

always a possibility of its acting as a carrier of disease germs, and yet we consider it a wholesome and trustworthy drinking-water. It might be improved by filtration, and since Pegan Brook has been purified, one source of serious danger has been removed; if others exist, they should be speedily corrected.

The reason why so much attention is paid to the microbes in drinking-water is not so much because they are proven to be disastrous to health, as that they belong to the same general category with the established germs of disease, and are, therefore, themselves suspected. Micro-organisms produce certain diseases, and micro-organisms are common in drinking-waters; hence it is, therefore, sometimes hastily concluded that drinking-water and disease yet go hand-in-hand. But so general a conclusion is not of necessity warranted by the facts. The micro-organisms in drinking-water are seldom the same as those present in disease, though the possibility of the presence of the latter must always be granted and kept in mind.

If, instead of asking what things, lifeless or living, *may* flow into the pitcher from the tap when drinking-water is drawn, we inquire what *does* ordinarily come in, we find that various humble plants and animals, along with the smaller micro-organisms, are not wanting, but that the malignant forms are not discoverable; and since this matter goes into the human alimentary canal, as such matter has gone ever since mankind began to drink, we know from experience what, in the majority of cases, will follow, namely, no harm whatsoever. The plants and animals, microbes and micro-organisms, whether dead or alive, mild or malignant, will simply be digested or passed out. The human alimentary tract has been practised in just such work from the time when our savage ancestors first slaked their thirst in stagnant pools until now. Here and there a weakling may be overcome, an invalid affected, or a strong man, under special conditions, upset or destroyed, but the vast majority will drink and feel none the worse. It is even questionable whether the removal of all the micro-organisms from the drinking-water of an ordinary city would perceptibly affect the death-rate.

At the same time, when we speak generally, and of possibilities, it must be laid down as an axiom that the purer the water-supply, the greater is the safety of the citizen. We cannot easily get rid of all the organic matters in drinking-water, nor is this necessary, except from a theoretical point of view. Most of the microbes present are perfectly harmless, and if all were removed, there would still be abundant opportunities for introducing them into the body through other channels.

There are, however, two ways in which organic matters in drinking-waters may be rendered harmless: 1, by removal (filtration); 2, by killing (heat). The latter is an easy, but not a sure method, since the spores of some microbes endure even prolonged boiling. Boiling is, however, a useful, simple, and inexpensive, though rough and imperfect method of protection. Filtration, formerly a mere straining, has, of late, aspired to *sterilize*, that is, to remove from the water all its living substances, however infinitesimal. In this event, the filtrate must be perfectly safe for drinking purposes, even the *possibility* of danger having been removed. Most filters do not claim such perfection, and most which do fail to reach it. The "Chamberland" filter is said to sterilize, and the micro-membrane filter invented by Breyer, of Munich, is claimed to do the same.

[The speaker then exhibited a micro-membrane filtering apparatus imported and previously exhibited by Professor Nichols. An ultra-marine mixture (in water), a fluid which filters with great difficulty, was shown to be perfectly decolorized by the apparatus.]

The essential part of this is a filtering surface of finely-divided asbestos. This is made by grinding the mineral in water, then mixing it with crystallized carbonate of calcium, grinding again thoroughly, and adding hydrochloric acid. The sharp edges of the crystallized carbonate seem to penetrate the asbestos, splitting it up — a process which is carried further by the escaping bubbles of carbon dioxide. In this way, fibres of extraordinary fineness are obtained, and, by other steps, made into filtering sheets or "lamels," which are easily arranged for filtration. Professor Nichols had made some experiments with the filter, but was not convinced that it would sterilize, although he granted its great perfection.

The speaker closed by affirming his full agreement with Professor Nichols in the following statements taken from a paper by the latter, upon the micro-membrane filter, read before the Society of Arts in April, 1886:

"Personally, I am quite content with the efficacy of the filter, and I think, in its larger forms, with attached reservoir, it may serve a good purpose. Of course, in this country, these small filters, which take an hour to filter a quart of water, would be quite useless. No one will wait fifteen minutes for a glass of water to filter through; he would rather take his chances for a few more microbes. I do not lay so very much stress upon this matter of "germs" in the present connection. First, because there is no proof that the number of microbes bears any direct relation to the wholesomeness of the water; second, because a water furnished or used for domestic supply ought not to contain *dangerous* organisms requiring removal; third, because, even if it were possible to obtain a germ-free water by carefully sterilizing the whole apparatus, and receiving the filtered water in sterilized vessels, such water would not be obtained in the ordinary use of the apparatus."

REPORT ON DISEASES OF CHILDREN.

BY T. M. ROTCH, M.D.

EXAMINATION OF URINE IN CHILDREN'S DISEASES.[1]

Dr. Alexandra J. Eckert, house-physician to the Elizaretinskaia Infirmary for Children, in St. Petersburg, states that she has made fifteen hundred analyses of urine in one hundred and four children, in order to study its changes under the influence of various affections attacking the child's organism, and to determine quantitatively the albuminoid losses sustained by the system in febrile albuminuria. The albumen in the urine was estimated after a method based on Heller's test and introduced simultaneously by Professor Roberts of Manchester, and Dr. J. J. Stolnikoff, of St. Petersburg, (see Professor V. A. Manassein's Sbornik Rabot, Part II, 1877.)

The author divides her cases into four groups. The first group consists of, (*a*) seven cases of typhus fever in children between the ages of six and fifteen: in this group, during the febrile period the urine was

[1] London Medical Record, October 15, 1886. Vratch, Nos. 44, 45.

scanty, high-colored, and of a high specific gravity; in five of the seven cases albuminuria lasting from four to twenty-one days was present, the quantity of albumen varying from 0.024 to 0.502 per cent.: it rapidly disappeared with the advent of pyrexia. (*b*) Nineteen cases of enteric fever, between the ages of three and fourteen. In fourteen of them albumen was found during the febrile period from four to fourteen days, its quantity varying from mere traces to 0.7 per cent. (*c*) Two cases of relapsing fever eight and eleven years old: no albuminuria was observed. (*d*) Three cases of intermittent fever between the ages of nine and twelve years; no albuminuria.

A second group included, (*a*) croupous pneumonia in twelve patients aged from eight months to twelve years, with scanty, highly-colored, and very dense urine during the febrile stage. In ten of them from a mere trace to 0.104 per cent. of albumen was found at the time of high temperature, for from four to seven days. (*b*) Catarrhal pneumonia in two patients aged seven and eight; in the former, who had fever of an intermittent type and ultimately recovered, the urine was scanty, had a high specific gravity and did not contain albumen; in the latter, 0.064 per cent. of albumen appeared shortly before his death. (*c*) Pulmonary tuberculosis, in four fatal cases between the ages of two and a half and ten years; albuminuria was present in all. (*d*) Chronic pneumonia one case, and exudative pleurisy one case; no albuminuria.

A third group consisted of, (*a*) measles, two cases, aged three and ten, with albuminuria of one to three days' duration, the amount varying from 0.012 to 0.067 per cent. (*b*) Diphtheria, faucial; two cases aged six and ten, with albuminuria of one to five days' duration, varying from 0.024 to 0.144 per cent. (*c*) Scarlet fever, six cases, aged three and a half to eight years; in five, albuminuria was observed and that in two forms (1) a febrile one during the efflorescence, of one to seven days' duration and with 0.012 to 0.044 per cent. of albuminuria, (2) a nephritic one, in the third week of the disease, of a month or longer duration, with 0.012 to 0.244 per cent. of albumen. (*d*) Parenchymatous nephritis, eight cases; in seven, albuminuria of one to six weeks' duration was found with 0.024 to 0.164 per cent. of albumen.

The fourth group consisted of, (*a*) a case of catarrhal angina with erysipelas, no albumen; three cases of tonsillitis 0.052 per cent. of albumen in one; four cases of intestinal catarrh 0.052 to 0.184 per cent. in one. (*b*) Non-febrile internal diseases, one each of scurvy, aortic stenosis, anæmia, cerebral tumor, dyspepsia, chorea, icterus, etc.; between the ages of five and fourteen years; no albumen, but a trace of albumen in a case of syphilitic interstitial hepatitis. (*c*) External affections in twenty cases between the ages of nine months and sixteen years: no albumen was detected, in eczema with nettle-rash, femoral osteotomy, fracture of the femur, and rheumatic synovitis of the knee. Albumen was, however, present in a fatal case of extensive burn, 0.184 per cent.; also of multiple lymphoma, 0.064 per cent.; rachitis with bed-sore, 0.008 to 0.124 per cent.; it was observed also in three of eight cases of caries, its quantity varying from traces to 0.024 per cent. Finally, albumen, from 0.024 to 0.244 per cent. was detected in three cases of vesical stone and cystitis, its source of course not being in the kidneys. The general conclusions reached by the author are given as follows:

1. All affections considerably disturbing the nutrition of the child's system and running their course in association with a high febrile state, give rise to albuminuria in a large majority of cases. 2. The characteristics of albuminuria are usually dependent upon the intensity of the morbid process and the duration of the febrile period. 3. As a rule, the albumen rapidly disappears after abatement or cessation of the fever. 4. Non-febrile affections, as well as those accompanied only by a slight, fleeting, febrile movement, seldom give rise to albuminuria of any considerable degree, and when they cause albuminuria, it occurs only as a phenomenon of very short duration.

ALBUMINURIA IN THE YOUNG.[2]

Dr. Eichhorst states that albuminuria frequently occurs during the period of growth; he has observed many cases which could not be attributed to any local affection, but which were evidently the consequence of a too rapid and precocious development of the body. The urine contained a more or less considerable quantity of albumen. The albuminuria preceded, in some cases, the first symptoms of general disturbance of health, by several hours or days, and ceased with such disturbance. The urine was of a pale yellow color and in only one case were hyaline casts and a few fat globules found. The attacks of albuminuria were repeated at intervals of weeks or months. The duration of each attack varied from one day to a week. The prognosis was favorable. Tonics and a long residence in the country was all the treatment required. The symptoms, according to Eichhorst, which accompany this kind of transitory albuminuria were:

1. Stiffness of the joints, lassitude, inaptitude for work, loss of memory. 2. Irritability, extreme mutability of character, and excitability. 3. More rarely, headache, vomiting, muscular tremors, and epileptiform convulsions of short duration.

[In this connection the investigations of Leroux, a summary of which is to be found in the Report on Children, *Boston Medical and Surgical Journal*, April 29th, 1886, will be of interest].

ACUTE YELLOW ATROPHY OF LIVER.[3]

Professor Monti, of Vienna, reports the following case: A boy, four years old, with a good family history, was taken sick with purpura December 4, 1884. The disease ran a favorable course, and by the 15th of March the child was entirely well. On the 6th of April, the child began to have nausea and vomiting. Temperature 38.5°, pulse 100, respirations 30; slight icterus; decided enlargement of the liver. Spleen normal; urine small in amount and icteric, and no return of the purpura.

The icterus became each day more pronounced, while the liver grew rather smaller. Vomiting next became a prominent symptom, and the child rapidly emaciated. On the 18th of April cerebral symptoms appeared, restlessness, delirium, and occasional unconsciousness. The temperature went up to 41.5° C., the icterus became still more marked, and the liver very little larger than normal; the spleen then became enlarged, and on the 22d of April, small, hæmorrhagic spots appeared on the skin, and there was epistaxis. The urine was small in amount, dark-colored from

[2] London Medical Record, October 15, 1886.
[3] Archiv. f. Kinderh., VII, 5, 1886. Schmidt's Jahrb., No. 10, 1886.

bile, and contained albumen, leucin, tyrosin, and hyaline casts.

On April 23d, there was coffee-ground vomiting and collapse. The temperature sank to 38.5°, the pulse was very weak, 130, and in the afternoon death took place after an eclamptic attack.

The autopsy gave simply the appearances of acute yellow atrophy of the liver. The peculiarities of this rare case lay in the connection of the attack of purpura with the liver atrophy, and the ease with which the daily decrease in size of the enlarged liver could be determined by palpation and percussion. The autopsy also revealed no complicating disease which could account for the high temperature which appeared when cerebral symptoms were first noticed.

SUBCUTANEOUS EMPHYSEMA.[4]

In the "Proceedings of the Vilna Medical Society," No. 12, 1886, a brief report is made by Dr. Roman M. Przybylski, of Vilna, of a rare case in a child, who, for a long period, suffered from cough, and then began to swell. On examination, there was found subcutaneous emphysema over the whole body, the skin being of a normal color and otherwise healthy. According to the author's theory, the occurrence of this phenomena may be explained by the bursting of some pulmonary alveoli in the presence of an extensive adhesion between the costal and pulmonary pleuræ, the air entering into the anterior mediastinum, and hence penetrating through the jugulum sterni into the subcutaneous alveolar tissue of the whole body. No pneumothorax was present. A similar case in a child has been reported by Wittman.[5]

CYANOSIS OF NEW-BORN AND ANILINE INK.[6]

In view of the cases of chromium poisoning reported at the June meeting of the Massachusetts Medical Society, the following cases are of interest: In July, 1885, four or five newly-born children in the Marylebone workhouse were found to be cyanosed, and suffering from very peculiar symptoms. Nothing could be detected to account for these phenomena, and after a few days, the children became quite well. No similar cases occurred until the following December, when seven children were attacked with analogous symptoms. After some time, one of the nurses discovered that these attacks had come on when a new supply of napkins was served out, and, on examining the ink with which they were marked, it was found to contain chloride of aniline. As soon as the napkins had been washed once or twice, the symptoms disappeared entirely. A newly-marked napkin was then applied experimentally to a healthy infant, and at once a train of symptoms arose, similar to those previously observed.

CHOREA MINOR FROM NASO-PHARYNGEAL REFLEX.[7]

Dr. A. Jacobi contributes an article on this subject, in which he states that bad habits are just as well the results of physical changes in the structure of the nerve-centres or their outlying provinces, as morbid changes in the functions of the coarser viscera spring from their anatomical alterations. He alludes to a number of convulsive movements of the face, winking, frowning, twitching of the angles of the mouth, and drawing up of the muscles of the nose, the mild cases sometimes improving spontaneously in the summer months, and getting worse in winter. Besides these anomalous movements, there are others which direct attention to the primary cause of the disorder, such as frequent snuffling and a short, hacking cough, the result of a voluntary effort. In these cases there is pharyngeal congestion, which is observed to ascend in the direction of the posterior nares. The mucous membrane of the nose is congested and swelled, and there is thickening and hyperæmia of the cavernous tissue, particularly of the lower concha. Nasal catarrh is reported as frequent in these cases. The local cause of this local or partial chorea is found in the abnormal condition of the nasal and pharyngeal mucous membrane, with its influence on the terminal sensitive ends of the trifacial nerve. The author assumes that the motor branches and terminal ends of the same nerve are first affected, and before any other nerves participate in the reflex symptoms. The motor branches of the trifacial supply the masticatory muscles, the temporal, masseter, and pterygoid, the tensor of the velum palatinum, the mylohyoid, the anterior belly of the digastric muscle, and the tensor tympani; and it is these muscles which are brought into abnormal play in the reflex symptoms described.

INFANTILE APHASIA.[8]

Professor Bernhardt, in an article on this subject, sums up as follows:

(1) Only about ninety cases of this disease have been recorded.

(2) Its etiological factors are nearly identical with those producing the affection in the adult, with especial reference, however, to the characteristics of childhood. The principal causes are reflex conditions after indigestion, entozoa, psychical irritation, infectious diseases, acute and chronic brain affections.

(3) It is chiefly a symptom of cerebral infantile paralysis.

(4) Hemiplegia does not necessarily exist with the aphasia.

(5) The affection may disappear spontaneously, especially after prudent and systematic physical exercise.

(6) The nature of the cerebral lesion in cases of aphasia existing since birth is not known.

[In this connection, a case of aphasia from fright is of interest; for description, see "Report on Children," *Boston Medical and Surgical Journal*, December 17, 1885.]

HYSTERICAL HEMIPLEGIA AND APHASIA.[9]

At a recent meeting of the Paris Biological Society, M. Gayot reported the case of a child four years of age, and previously free from any nervous symptoms, who, after being violently agitated, was seized with hemiplegia of the right side and aphasia; the motor and sensory faculties were also impaired. In a few days the hemiplegia disappeared, but returned the next morning. The following night, the sensory and motor faculties regained their normal activity, and the child's health has since been good. Each return of hemiplegia was accompanied by aphasia. Both parents were of an excessively nervous temperament.

DIAGNOSIS OF INFANTILE DISEASES.[10]

In a recent number of *L' Union Médicale du Canada*, Dr. Bradley gives the following summary of points on the diagnosis of disease in infants:

(1) Congestion of the cheeks, excepting in cases of cachexia and chronic disease, indicates an inflammation or a febrile condition.

(2) Congestion of the face, ears, and forehead of short duration, strabismus, with febrile reaction, oscillation of the iris, irregularity of the pupil, with falling of the upper lids, indicates a cerebral affection.

(3) A marked degree of emaciation, which progresses gradually, indicates some sub-acute or chronic affection of a grave character.

(4) Bulbar hypertrophy of the fingers and curving of the nails are signs of interference in the normal functions of the circulatory apparatus.

(5) Hypertrophy of the spongy portions of the bones indicates rachitis.

(6) The presence between the eyelids of a thick and purulent secretion from the Meibomian glands may indicate great prostration of the general powers.

(7) Passive congestion of the conjunctival vessels indicates approaching death.

(8) Long-continued lividity, as well as lividity produced by emotion and excitement, the respiration continuing normal, are indices of a fault in the formation of the heart or the great vessels.

(9) A temporary lividity indicates the existence of a grave acute disease, especially of the respiratory organs.

(10) The absence of tears in children four months old or more suggests a form of disease which will usually be fatal.

(11) Piercing and acute cries indicate a severe cerebro-spinal trouble.

(12) Irregular muscular movements, which are partly under control of the will when the patient is awake, indicate the existence of chorea.

(13) Contraction of the eye-brows, together with a turning of the head and eyes to avoid the light, is a sign of cephalalgia.

(14) When the child holds his hand upon his head, or strives to rest the head upon the bosom of his mother or nurse, he may be suffering from ear disease.

(15) When the fingers are carried to the mouth, and there is, besides, great agitation present, there is probably some abnormal condition of the larynx.

(16) When the child turns his head constantly from one side to the other, there is a suggestion of some obstruction in the larynx.

(17) A hoarse and indistinct voice is suggestive of laryngitis.

(18) A feeble and plaintive voice indicates trouble in the abdominal organs.

(19) A slow and intermittent respiration, accompanied with sighs, suggests the presence of cerebral disease.

(20) If the respiration be intermittent, but accelerated, there is capillary bronchitis.

(21) If it be superficial and accelerated, there is some inflammatory trouble of the larynx and trachea.

(22) A strong and sonorous cough suggests spasmodic croup.

(23) A hoarse and rough cough is an indication of true croup.

[10] London Medical Record, October 15, 1886.

(24) When the cough is clear and distinct, bronchitis is suggested.

(25) When the cough is suppressed and painful, it points towards pneumonia and pleurisy.

(26) A convulsive cough indicates whooping-cough.

(27) A dry and painless cough is sometimes noticed in the course of typhoid and intermittent fever, in difficult dentition, or where worms are present.

Reports of Societies.

THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, October 21, 1886.

DR. FRANCIS DELAFIELD read a paper on

PULMONARY EMPHYSEMA.

Having given a general statement of the varieties, causes, symptoms, physical signs, prognosis and treatment of emphysema, as set down in the standard text-books, he remarked that the student, when he came to observe for himself, was often surprised to find that the characteristics of the affection, as it actually occurred in practice, did not correspond with the description given by the great mass of authorities. He would find that it necessarily arises in connection with bronchitis, and that playing on wind-instruments was not one of its common causes. He would find that it did not afford such immunity from phthisis and pneumonia as was commonly taught; and if he made autopsies, he would find that the dilatation of the air-vesicles and air-spaces was by no means always proportionate to the severity of the symptoms that had been present during life.

It was true that chronic bronchitis and attacks of asthma were frequent enough, yet there were other cases in which such conditions were entirely absent, and substantive emphysema was essentially different from what the classical descriptions of it would lead us to believe. It was, therefore, important to decide what we really do know, and what we do not know about the disease. It was well, on the whole, to divide the varieties, according to the recognized classification, into the inter-lobular or interstitial, and the vesicular forms, and to divide the latter into senile, lobular, and substantive.

Senile emphysema was due simply to a senile change in the parenchyma of the lungs; and when it was present there was no obstruction to the passage of blood through the lungs, and no dilatation or hypertrophy of the right side of the heart. Chronic bronchitis was often present, but the affection was not severe, and of no very grave import. In some instances, substantive emphysema commenced in the earlier portion of life, and as the patient grew older, senile emphysema occurred also. It was not always easy to distinguish between the two; and yet the distinction was very important, for while substantive emphysema was a very serious affection, the senile variety, as had been mentioned, was not.

Dr. Delafield then went on to say that substantive emphysema was, in reality, a form of pneumonia. It was, in fact, an inflammation of the same type as that which so often attacks the endocardium, the arteries, the kidneys, and the liver. The walls of the vesicles were first attacked, and while some of them became

thickened, others became thin. The dilatation, both of the vesicles and the air-spaces, varied in different cases, and was by no means proportionate in many instances to the severity of the symptoms present. In fact, many of the cases were overlooked at autopsies, because there was no dilatation of the air-spaces visible to the naked eye. Later on the emphysema spread, and attacked other parts of the lungs, including the epithelial cells lining the air-spaces, and the mucous membrane of the bronchi. The pleura also became thickened, numerous adhesions formed, and the whole condition was, in short, that of interstitial pneumonia. In the milder cases, there was but little disturbance of the circulation of the blood, but in the severe cases this gave rise to the worst symptoms. The right ventricle of the heart became hypertrophied and dilated, and venous congestion and dropsy followed. The secondary symptoms were, indeed, the same as those of valvular cardiac disease. Having referred to the various complications liable to arise, he stated that this affection was very frequently met with in New York, coming on, as a rule, in individuals of from forty to forty-five years of age. Hereditary influences were marked. The same causes were active in producing it, as in the case of chronic endocarditis, arteritis, nephritis, etc. It was of more importance to recognize the cases of moderate severity than the very bad ones, because in the latter, comparatively little could be done in the way of treatment. In the moderate cases there was no change in the shape of the thorax, though, in old and aggravated cases, the barrel-shaped chest was not infrequently present. The pulmonary resonance might remain unaltered for a considerable time.

Having spoken in detail of the physical signs present, Dr. Delafield said that the emphysema might continue for years without giving rise to any rational symptoms. The condition, however, could be generally recognized by taking into consideration the age and general condition and tendencies of the patient. There were other cases in which the presence of Bright's disease or cardiac trouble caused the emphysema to be lost sight of. The dyspnœa, at its worst, was constant and extremely distressing. In the bad cases there were also severe cough and venous congestion, followed by general dropsy.

The disease might pursue a number of different courses. In the first place, a patient who had suffered a long time from winter cough, and was always a little short of breath on making exertion, would at length develop spasmodic asthma. Then would follow increasing dyspnœa, loss of flesh and strength, venous congestion, dropsy, and death. Another class of patients would be apparently entirely well, except when they had an attack of acute bronchitis. After a time, however, venous congestion, albuminuria, and dropsy would ensue, as in the preceding variety. Still another class would suffer for years from spasmodic asthma before the evidences of emphysema would show themselves. Finally, there was a class of cases in which the symptoms were very slight for a long time, when venous congestion and the other grave symptoms would suddenly become developed. The behavior of the affection was, therefore, on the whole, very like that of the atrophic form of chronic Bright's disease.

In speaking of the treatment, he said that the same general rules as regards hygienic surroundings, climate, mode of life, etc., which had a favorable effect on the progress of other affections of the same class, such as chronic Bright's disease, etc., were applicable in emphysema. It was a question of some importance whether the dyspnœa and asthmatic attacks which so frequently characterized it were not due, in reality, to a contraction of the arteries and capillaries, since it was found by experience that many of the drugs the most serviceable in relieving these conditions were those the physiological effect of which was to produce a relaxation of the walls of these vessels.

The conclusions arrived at by Dr. Delafield were somewhat as follows: Emphysema is not a chronic local disease due to excess of inspired air over expired air, or to fatty degeneration, but a chronic inflammation of the lungs; nor is the dilatation of the air-cells and air-spaces an essential part of the affection. The result of this inflammation is such an irregular thickening and thinning of the walls of the air-spaces as would naturally occasion the dilatation of some of them. The dyspnœa and general venous congestion are not due simply to the dilation, but to the contraction of the pulmonary bloodvessels. Excessive bodily exertion is not the cause of emphysema. In the treatment, the indications are to delay the progress of the chronic inflammation and to overcome the contraction of the bloodvessels present. Chronic bronchitis is, of course, to receive proper attention. [At the conclusion of the paper Dr. Delafield had exhibited, by the aid of the magic lantern, a number of sections of lungs taken from different patients illustrating the points referred to in it].

Dr. E. Darwin Hudson, Jr., said that the author of the paper had given his ideas of emphysema from a pathological point of view. Personally, he was more accustomed to regard it in a clinical aspect, particularly in connection with the physical signs to which it gave rise; although he had had the opportunity of studying the disease to a considerable extent in the dead-house also. His post-mortem experience, however, was, of course, limited when compared with that of Dr. Delafield. He had always looked upon the account of emphysema given by Waters, of Liverpool, as affording a very definite and accurate idea of the affection. In his paper, Dr. Delafield had described other diseases, more particularly interstitial pneumonia, with emphysema. He (Dr. Hudson), was still of the opinion, however, that we had to take emphysema as a distinct type, and that it consisted essentially in rarefaction of the pulmonary structure, as described in "Reynold's Practice" and other standard works. The clinical history of the disease had to be taken into consideration, as well as the pathological conditions found after death.

It was very common for women at the climacteric period to become obese and develop emphysema, with the barrel-shaped chest so often described as characteristic of the affection. Hence the condition could hardly be due to alteration in the anatomical structure of the lung; though no doubt this was the case in other instances. The results obtained from Voldenberg's apparatus, and more recently from Ketcham's pneumatic cabinet, throw considerable light on the nature of emphysema; which was shown to be a disease in a large number of cases in which there was a loss of elasticity and resiliency on the part of the air tubes and vesicles. It was no doubt true that in a certain number of instances that gouty diathesis was present, with interstitial disease of the kidneys, or

other characteristic lesions; but there was a very large number of other cases in which the affection was purely mechanical.

DR. C. HEITZMAN said it was now fifty years since Rokitansky gave to the profession an accurate knowledge of emphysema, and that ever since then its pathological and clinical characteristics had been well known. It seemed to him that either Dr. Delafield had not seen a pure case of the affection, or had not demonstrated one. The sections which he had exhibited this evening were certainly not specimens from simple emphysema. As Dr. Hudson had stated, they were emphysema combined with interstitial pneumonia. It was, indeed, not a primary, but a secondary disease. He had in his possession an ample number of specimens taken from cases of pure emphysema, and they are altogether different from those which Dr. Delafield had shown. As to the pathology of the affection as interpreted by Dr. Delafield, namely, that it was due to contraction of the bloodvessels, he did not see why we should go to something which we could not prove for an explanation of the trouble. For himself, he was content to believe in the old view of the affection.

DR. DELAFIELD said that the ideas which he had tried to set forth in the paper were those which he had formed from a somewhat extended study of the disease both during life and after death. The treatment which was found most effectual in emphysema was certainly fully compatible with the views which he had advanced.

DR. VAN ZANTVOORD said that he had at present under observation two advanced cases of emphysema which seemed to him to bear out the statement of the author of the paper that the affection was of great gravity in many cases; and since he had been in practice he had found out that many of the teachings in regard to emphysema which he had heard when a student were not borne out by the facts. He then spoke of the great value, according to his experience, which caffeine had as a cardiac stimulant in these cases. The right heart was frequently embarrassed, and venous congestion was apt to occur long before it could be caused by tricuspid trouble, or at least before this could be recognized by the physical signs.

DR. DELAFIELD said that he thought caffeine a useful drug. It appeared to stimulate the right side of the heart more than the left side; and the same was true of convallaria. Just as was the case in pneumonia, it was therefore indicated to stimulate the right heart in emphysema.

The President, DR. A. JACOBI, spoke of the value of the iodides, and said that the benefit which was afforded by them could only be explained on the ground that they acted as absorbents.

DR. F. A. CARTH said that of late calcium chloride, which had been proposed a long time since in this connection, had been steadily growing in favor for the purpose of causing absorption of connective tissue products. He referred to the value in emphysema of remedies which relax the muscular coat of the bloodvessels, and said that he thought this had a direct bearing on the subject of the paper. For instance, the prompt relief afforded by nitrite of amyl would seem to indicate that the seat of the trouble was in the bloodvessels; for if the dyspnœa were due simply to dilatation or to the presence of mucus in the air-vesicles, one could hardly account for the favorable action of this remedy.

DR. DELAFIELD said that he agreed with the President that the iodides were among our most valuable drugs in emphysema, and its action might well be supposed to be due to their effect on the bloodvessels, because it was a recognized fact that one of their effects is to relax the swollen bloodvessels. Thus, iodide of potassium was given in cardiac disease for its effect on the small arteries and capillaries. Another drug of the same class which was of great value was chloral hydrate, which acted in a similar manner. Large doses of chloral were extremely useful in acute attacks of dyspnœa, and small doses in chronic dyspnœa.

MASSACHUSETTS MEDICAL SOCIETY.
SUFFOLK DISTRICT.
SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

MEETING October 13th, 1886.

The meeting was called to order by the Secretary in the absence of the Chairman, and on motion, DR. V. Y. BOWDITCH was elected Chairman, *pro tem.* The reading of the records of the last meeting, relating to the subject of the Physical Training of Children in our Schools, was omitted.

The Secretary read a letter from Prof. Raphael Pumpelly, of Newport, in which he expressed his deep regret that an unforseen accident would prevent him from attending the meeting as he had expected to do.

PROF. T. W. SEDGWICK read an essay upon

THE FILTRATION OF POTABLE WATERS, WITH REFERENCE TO THE ELIMINATION OF ORGANIC GERMS.[1]

The speaker considers the quality of drinking-water a matter of great importance, but seems to incline to the opinion that many of the impurities in the water we drink, though objectionable to sight, taste, and sentiment, are not directly the cause of serious disturbance to the human organism. A general description of the essential composition of any appliance for the filtration of water, was followed by the exhibition of the Micro-membrane Filter, which was in practical operation in a solution of ultramarine, from which it delivered a filtrate of such purity that it was impossible to tell it from the filtered Cochituate water which had not been stained with this coloring matter. The meshes of asbestos composing the filter were of such a degree of minuteness that the small particles of coloring matter were entirely separated from the water, and a clear filtrate was obtained. [For a more detailed description of the Micro-membrane Filter, see Report of the late Prof. W. R. Nichols, in Proceedings of the Society of Arts, of the Massachusetts Institute of Technology, 1885–86.]

The Chairman called upon DR. S. W. ABBOTT, Secretary of the Massachusetts State Board of Health, who responded as follows: There are two things to be borne in mind in the study of filtration of water; one relates to the well-being of the consumer, and is of use only as it modifies the actual condition of the water; while the other relates to the financial success of the company manufacturing the filter. Filters as now made, are all more or less defective, and accomplish the ob-

[1] See page 470.

jects for which they are manufactured with more or less completeness. If we could have a filter which would adequately protect the consumer of the water against the contamination which may, and too frequently does exist in drinking-water, we should have a good thing. A filter is a thing which is the subject of many erroneous ideas on the part of the public. All filters containing charcoal, silica, etc., will remove a certain amount of dirt from the water, and the popular idea seems to be that thereby they actually protect the public from the effects of contaminated water. This is a positive mistake, but many people are firmly persuaded that filtration transforms an injurious water-supply to a wholesome one.

Thus we were recently treated to the authoritative statement from the pen of a clergyman not more than twenty miles from Boston, that if a certain filter made by a certain manufacturer had been employed in the town of Plymouth, Pa., in which there recently prevailed a frightful epidemic of malignant fever, causing more than a thousand deaths, not one person would have died from the disease. We cannot accept such statements as these, and for the same reason we cannot put reliance upon any appliance for the mechanical purification of drinking-water until it is proved to do more than any filter is now doing. In regard to the micro-membrane filter it must be remembered that this is a new instrument, and it might not do so good work after a certain period of use, as it now does. If it could be enlarged, it would seem to offer the promise of a really good and serviceable filter. It looks as if it might exclude bacteria. If any form of filter could be devised which might be applied to the water at its source of supply, instead of at the end of the service, it would be a vast improvement over any present system.

Dr. J. G. Blake said that he was glad to be able to testify to the efforts on behalf of the Water Board of the City of Boston toward improving the quality of the water-supply. There is no question that the character of the water furnished to the citizens is now much better than formerly. The subject of filters is a broad one, and much misapprehension doubtless exists upon their design and usefulness. A filter is no more than a strainer, and will do the mechanical work of a more or less perfect strainer, and that is about all it will do. The ordinary filter is much too small for useful service, and can do only imperfectly the duty of separating the extraneous matters in water, as is usually seen in the action of most filters. The amount of filtering material is ordinarily far too small to properly strain out the foreign substances or to furnish even an approximately pure water. If the micro-membrane filter can be made practicable and be constructed cheaply, it would seem to be a good thing.

Mr. Desmond Fitzgerald, of the Cochituate Water Board, was called upon by the Chairman, and responded by saying that he was much interested in the subject before the meeting, and would gladly add to the knowledge of the matter if it were in his power. The subject of the purification of our drinking-water is one which attracts the attention of the public, as is evidenced by the size of the present assembly. There is one remarkable thing about the whole question of sanitation, which is, that it is only since the time that science has taken the subject in hand that there has been any real improvement in the means of furnishing pure water to urban populations for domestic purposes. It is only since scientific men have devoted their energies to the accomplishment of better sanitary conditions that there has been an appreciable diminution in the death-rate from any of the well-known epidemic or infectious disorders which affect the human race. From the period when sanitation became an established science, there has been a steady improvement in the public health. There is no question that much of the epidemic disease in London was directly or indirectly traceable to the old wells which were formerly the sole water-supply of the city for domestic purposes.

The whole question of the filtration of water will resolve itself into two propositions. First, does it pay? Second, can the various impurities in water be removed by this means?

Can filtration remove the color from impure water? Can it abstract the albumenoid, ammonia and other chemical contaminations? Until a filter can be produced which shall answer these demands, this appliance will not come into general use. In England much of the water-supply for large towns is taken from rivers, and previous to being diverted into the service-pipes, the water is treated with substances which chemically remove much foreign matter which would otherwise pass into the domestic supply. With respect to the micro-membrane filter, the question to be asked is, will it clog? will it remove chlorine? will it still continue to remove these impurities after a period more or less long of active service? At present all forms of domestic filters are simply strainers. We have not arrived at perfection in the manner of distribution of water-supply, and are farther still from the practicable and reliable means of its purification. What we want is to get at the way to deliver to a city of the size of Boston a supply of pure water every day. Filtration to be most effective should be conducted in such a manner that the water may pass slowly through the filtering medium, and thus allow the detention of deleterious matters. Rapid filtration is not in accordance with the principles of perfect separation of impurities.

Dr. Blake asked the probable cost of filtration of service water on a large scale. Mr. Fitzgerald replied that the cost would not probably be so large as to interfere with its practicability, if a useful method could be devised.

Prof. Geo. F. Swain, of the Massachusetts Institute of Technology, being introduced by the Chairman, said that it is not necessary to remove all the germs from the drinking-water, even if this were possible. The place for the removal of organic matter is not at the delivery of the water in the house of the consumer, but it is at the source. The dirt in the state of mechanical suspension can be removed by a simple filter at the point where the water is drawn for use. In regard to filtration on a large scale, it is simply straining, and not filtration in any proper sense of the word. Prof. Swain then described a new appliance for the purification of water for domestic purposes as follows: At the request of the manufacturer, who is unfortunately unable to be present this evening, I will briefly explain the construction and operation of the Diamond Filter. This filter is intended to be attached directly to the supply-pipe, taking the place of a faucet, and it consists of a cast-iron enamelled cylinder, to which a top is screwed, the water entering at the bottom and passing out at the top. The filtering material consists of two layers of quartz sand with

an intermediate layer of bone charcoal, closely packed, between two brass gratings to which are soldered screens of fine brass wire. The area of cross-section of the filter being very much larger than that of the inlet-pipe, the velocity of the water through the filtering medium is very much reduced, and the coarser particles settle below the lower grating or are caught on the wire-screen, while the finer ones are intercepted by the lower layer of quartz, very little even reaching the charcoal, which therefore needs renewal but seldom.

The principal peculiarity of the filter lies in the method of cleansing. It is divided internally by a vertical solid partition, and at the inlet a four-way cock is placed. The two upper openings are inlets, and the two lower ones outlets, leading to the discharge-pipe just below the inlet; the inlet and outlet on the right being connected with the right-hand half, and those on the left with the left-hand half of the filter. In ordinary working both inlets are open and both outlets closed, the water entering on both sides and ascending through the whole body of the filter; but if the filter is to be cleansed the outlet valve or cock is closed, and the four-away cock is turned so that the left-hand (upper) inlet, and the right-hand (lower) outlet are closed, the water passing in at the right, up through the right-hand half, down through the left-hand half, and out through the outlet, thus cleansing the left-hand half with *filtered water*, a point upon which the inventor lays great stress. By turning the four-way cock so that the right-hand inlet and left-hand outlet are closed, the course of the water may be reversed, and the right-hand compartment cleansed. Finally, if the water contains such finely-divided particles as to be but imperfectly filtered in the ordinary manner, the usual outlet valve may be closed and the water drawn from the lower discharge, after having been made to pass up and down through the filter.

The filtering material is renewed by unscrewing and removing the top.

The ordinary sizes of this filter, which is made by John G. Avery, in Spencer, Mass., are: No. 1, 4 in. diam., 6 in. high, 4 in. of filtering material, price $10; No. 2, 6 in. diam., 8 in. high, 6 in. of filtering material, price $15; No. 3, 12 in. diam., 15 in. high, 11 in. of filtering material, price $35. Very much larger sizes, however, have been made in special cases.

DR. HENRY J. BARNES spoke at some length of the desirability of securing the utmost degree of cleanliness in the fluid we use as a drink, and continued as follows: The desirability of filtering the water-supply of Boston has been greatly diminished, through the influence of members of this, and the parent Medical Society exercised chiefly through the valuable services of Dr. John G. Blake, a member of "The Commission of Investigation," since which the storage basins on the Sudbury River have been relieved of a large amount of vegetable mould, the decay and disintegration of which loaded the water with a great volume of organic matter. There has been little to complain of in the character of this water. At the present time these storage reservoirs are practically in the condition of "natural ponds," polluted to a greater or less extent by organic matter both animal and vegetable, dead and alive, washed into the basins with every rainstorm of magnitude, beside no inconsiderable amount of sewage which the praise-worthy efforts of the Water Board and engineer have failed to exclude. Nature strives and in a manner succeeds in neutralizing this banefu. influence by inhabiting the water with living organisms which devour the dead, prey upon the living, and transform organic into inorganic matter. Insects, fishes, mollusks, crustaceans, diatomes, and other species of animalcules each and all contribute to this end. And it is therefore undesirable, even if possible, to defertilize it at this point.

The bacteria of putrefaction, consuming oxygen, convert nitrogenous matter into plant-food. Vegetation inhaling carbonic acid and exhaling oxygen, renders it possible for animal life to exist.

The algæ selecting food from elements set free by decomposition, the spongilla subsisting upon animalcules and the spores of the algæ are but steps, which, if properly balanced, contribute towards purification. The balancing of these organisms, the ideal condition of a water-supply, is not to be hoped for where so many factors interfere with harmony. Unconsumed animal and vegetable material with the coagulæ of imperfectly decomposed soluble matter finds its way into the service pipes, for which we have no means of elimination except by filtration. It is here shown by the working of these filters to be considerable, and I do not believe its consumption conducive to the best hygiene. Nature strains it all out in converting surface water into spring water. If we can imitate her by artificial devices it is certainly desirable, and it does seem as if many of these machines do excellent service in this direction. While advocating their use, then, for the Sudbury and Cochituate service, I should deprecate the establishment of the notion that any are capable of freeing water from those noxious elements which go to make up six-sevenths of the pollution where sewage is discharged. The dissolved nitrogenous matter in urine, the almost completely soluble fæcal discharge must of necessity pass through any mechanical obstruction the mesh of which is capable of transmitting the liquid vehicle.

For this reason, water contaminated as in our Mystic supply, with human excreta, washings from tanneries, currying-shops, glue-factories, piggeries, etc., cannot be materially benefited by any of these appliances. By chemical treatment, a portion of the soluble matter can be precipitated, but of the great variety of methods employed, but few produce an effluent from sewage which should be discharged even into water not used for domestic purposes. One of the simplest and best plants for this purpose is employed at Stroud, Eng.,— and known as the "Bird process." Impure sulphate of alumina and sulphuric acid are the agents. The acid is added to powdered clay a few days before it is used, from a hopper regulating the discharge, into a current of sewage which goes to the first reservoir of deposit. From this receptacle it runs under another hopper discharging clay mixed with sulphuric acid to a second reservoir, and from thence over three lays of filtering coke. Analysis of the influent and effluent water shows in parts per 100.000 in weight, the water before treatment to contain 48.5 soluble and insoluble matter; after, 53.5.

	Before.	After.
Organic Carbon	2.289	2.203
Nitrogenous matter	2.859	1.779
Ammonia	6.000	5.000
Nitrogenous matter in combination	7.800	5.887
Matter in suspension, mineral and organic	43.000	4.008

This result, though obviously good, cannot be considered satisfactory epuration for domestic purposes.

Clay will promote decomposition of nitrogenous matter when brought in contact with the lime it contains, and the alum will cause a precipitation. But this has proved an unsatisfactory method in the treatment of sewage at Tottenham, although complete clarification was secured before discharging in the river Lea. A flocculent deposit collected on the bed of the river of highly putrescible character.

It is obviously impossible to treat potable water with clay, even if a more satisfactory result could be attained.

The more complicated methods of chemical treatment, such as Hille's, Goodall's, Holden's, Campbell's, and Scott's processes; the A. B. C. process of Sillar; the lime and chloride of iron treatment afford little assurance of successful epuration, and many of the agents employed would be objectionable in a water-supply.

Dr. Frankland wrote a few years ago, "The actual resources of chemistry do not permit the hope that the dissolved impurities in sewage can be precipitated by any appliance of chemical reaction, and unless new chemical laws are discovered, it is useless to attempt the employment of this agency.

Soil purification, though capable of transforming sewage into potable water, opens up a subject beyond the limits set for consideration this evening, and it is not applicable to the purification of water in open sewage basins, except so far as filter galleries will eliminate a certain amount of material in suspension.

"It is difficult to reconcile the apparent difference of opinion between scientists of America and Europe. In the latter country filtration is almost universally practiced. The British army in Africa was supplied with portable filters presumably by the advice of the medical department. Such men as Lister, Frankland, Alfred Clarke and many others certify to the usefulness of a good filter. I have used one in my family since 1882, and there has never been a time even when water from the unexcavated basins on the Sudbury river was supplied that all the apparent organic matter in suspension was not removed, besides decolorizing the water by the ordinary tests."

Dr. H. C. Ernst said that he desired to protest against the view apparently advanced by Professor Sedgwick, that the indiscriminate and unhindered swallowing of bacteria in any and all forms is harmless, not to say wholesome. No person who has ever witnessed the results of the ingestion of the germs of cholera, either in the way of an epidemical outbreak of that disease, or as a means of research in experimental pathology, could entertain such an idea for a moment. The sterilization of water by filtration has been tried in a very thorough manner in the laboratory of Professor Koch in Berlin. Many different kinds of filters were employed, and the resulting filtrate was tested as to its freedom from germs by means of culture-plates. None of the common forms of filter were found to be bacteria proof. Only one was found which was capable of arresting the germ contents of water. This was the filter devised by Chamberland in Professor Pasteur's laboratory. In most of the filters it was observed that the germs grew rapidly in the filter, and soon penetrated the wall of the filter by direct growth from the other side, and thus appeared in the filtrate in large numbers.

Professor Sedgwick stated that he by no means wished to be understood as believing that it was safe or prudent to employ polluted water for domestic purposes. He said that there was no doubt on the other hand that a vast number of germs were undoubtedly taken into the human organism every day, and there is usually no serious result from their ingestion. Of course there are microscopic germs, which are harmful or even destructive to the animal body, and these can never be taken except on peril of great disturbance to the functions of the body, but there are also a vast number of germs which may be, and are taken into the body without perceptible detriment.

The Chairman announced that he had received a communication from a delegation of the Society upon the subject of Physical Culture, and desired to refer the matter to the Section for their action. On motion of Dr. Bradford the subject was referred to a committee of three to be appointed by the chair, to report on the same at the next meeting. The chair appointed as that committee, the following: Dr. E. H. Bradford, Chairman, Dr. C. P. Putnam and Dr. J. P. Reynolds.

The Secretary announced that he had just received a letter from the Secretary of the Middlesex South District Medical Society, stating that a committee had been appointed from that Society to co-operate with the committee from this Section in the matter of urging the adoption of some plan for the physical training of school-children. The committee so appointed consisted of Drs. E. Farnham, C. H. Cook, and H. P. Walcott.

A variety of filters of various forms and structure was arranged upon the table, some of which were portable, and some of which were attached to the service-pipes of the building. The following filters were explained by representatives of the manufacturers or owners. Micro-membrane Filter, by Professor Sedgwick; Sanitary Improvement Co.'s, by A. P. Howe, Esq.; "Filtre Rapide" (Maignen's), Blanchard, Farrar & Co., by Mr. Blanchard; Cheevans, Jones, McDuffee & Stratton, by Mr. Jones; Diamond Filter, by Professor Swain; American Filter.

Adjourned at 10.30 o'clock.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

HERBERT L. BURRELL, M.D., SECRETARY.

October 30, 1886, the President, Dr. G. B. Shattuck, in the chair.

Dr. G. H. Monks reported

A CASE OF UNUSUAL DEFORMITY OF BOTH HIP-JOINTS, AND EXHIBITED THE PATIENT.[1]

Dr. A. N. Blodgett asked if there were any nervous lesion present in the case that might account for the remarkable difference in development of the upper and lower extremities of the patient. He further called attention to a peculiar, claw-like action of the feet when the patient was walking.

Dr. Monks said that he knew of no nervous lesion.

Dr. R. M. Hodges inquired what evidence there was that the deformity had only existed two years.

Dr. Monks said that careful questioning of the patient and his parents were the basis for the statement.

Dr. E. W. Cushing inquired if the patient had ever

[1] See page 468.

had any acute infectious disease; if he had ever had acute rheumatism or gonorrhœa.

DR. MONKS replied that he had not.

DR. PRINCE inquired about the reflexes.

DR. GREENOUGH asked if the pelvis moved with the femora; if there were complete ankylosis.

DR. MONKS said that the pelvis practically did move with the femora, as there was only a very limited degree of motion.

DR. BARNES inquired if the flat-foot were acquired.

DR. MONKS said that he could not say how that was.

DR. OTIS K. NEWELL then read a paper on

THE MALE URETHRA: SOME OBSERVATIONS ON THE ANATOMY OF, IN RELATION TO ENDOSCOPY, LITHOLOPAXY, AND CATHETERIZATION.[2]

DR. CABOT inquired if the short tube could be introduced without bringing it down to the axis of the body.

DR. NEWELL replied that it could.

DR. CABOT asked if the tube would stay in position after the tube is brought to angle of 45°.

DR. NEWELL said that it would, owing to the large size of the tube engaging the circumference of the prostatic urethra.

DR. CABOT said that in certain cases where there were deep, long prostates, he had encountered some difficulty in making an evacuating tube retain its position.

DR. NEWELL said that in ten subjects he had been able to introduce his tube so that from one and a half to two inches of tube protruded from the vesical orifice into the cavity.

DR. M. H. RICHARDSON said that he had used Dr. Newell's endoscope with success, and felt that with more experience in its use, that he should be able to obtain valuable information. In one case, he said that he had been enabled to settle a question regarding the presence of a tumor in the bladder.

Recent Literature.

Elements of the Comparative Anatomy of Vertebrates: Adapted from the German of Wiedersheim, Professor of Anatomy, etc., at Freiburg in Baden. By W. NEWTON PARKER, Professor of Biology in the University College of South Wales and Monmouthshire. With additions by the author and translator. London: Macmillan & Co. 1886.

This book will be useful to those who desire to find in a convenient form the main facts of vertebrate anatomy. It will also be very valuable as a text-book in a course considerably amplified by the teacher. The defect of overcompression is almost unavoidable in a work of this nature. It is most difficult to know where to draw the line, and we think that the author has shown wisdom in the limits he has imposed. Once in a while a very few additional words would be of great advantage. Thus on page 287, there are figures of five different arrangements of the great vessels from the aortic arch in mammals, but the student is not told in which animals they occur. The plan adopted is the very practical one of following the same organ or system throughout the vertebrate classes. This makes it much easier for the student who wishes to look up some particular point. The book is very thoroughly illustrated, and many of the diagrams are admirable for their clearness and simplicity. We notice a gross error in the figure of the human sternum, which we suspect must have been added by the translator, as it could hardly have escaped the notice of a professor of human anatomy. Many of the illustrations are old friends, but of the kind that we can hardly meet too often. To our mind, a defect in the book is the admission of theories here and there into a work which should be only the record of facts; but this fault is nowadays almost a matter of course. The book is written for students of medicine, as well as for those of comparative anatomy, and we think it will be welcome to both. T. D.

Spasm in Chronic Nerve Disease. By SEYMOUR J. SHARKEY, M.A., M.B., etc., of London. 8vo. 99 pp. London: J. & A. Churchill. 1886.

This volume consists of the Gulstonian Lectures for the present year. The subject is treated under three heads: spasm in connection with cerebral motor mechanisms, spasm in connection with spinal mechanisms, and functional spasm. The consideration of the forms of spasm seen in convulsive diseases, like epilepsy is not dwelt upon. Under the first head he considers especially those conditions of muscular rigidity and contracture seen after cerebral disease, such as hæmorrhage, softening, tumors, porencephalia, etc.; and also certain conditions of mobile spasm, like athetosis and post-hemiplegic chorea. "The pyramidal tract stands prominently forth as the great offender in the production of muscular spasm. . . . It only looses the reins of the spinal centres, which it should keep well in hand. Still, it rules the situation. . . . The symptoms of disease of the lateral columns of the cord are the same, whether it follows cerebral or spinal lesions." He also quotes cases of hemiplegia, where there was no direct lesion of the pyramidal tract, and consequently, as he thinks, no signs of rigidity ever appeared. This theory, although very probable, is not, however, universally admitted, and it would seem strange, were it not for the too common ignorance of German work which English writers seem to show, that, in such a treatise no mention is made of the views of those who hold that contracture and late rigidity in hemiplegia have nothing to do with secondary degeneration of the pyramidal tract. Contracture, he says, is seen in peripheral diseases, but many of the cases may be explained by a contraction of antagonistic muscles, as in *main en griffe*, or by contractile processes due to disease of the muscles themselves. Pain, trauma, or joint-disease might not produce contraction if the centres were normal. An involuntary neuro-muscular habit may explain such cases. Functional spasm resembles spasm from gross lesions, and is thought to be due to molecular changes analogous to the gross changes. In some of these cases, as in writers' cramp, the part of the pyramidal tract involved is fatigued, the lower centres are "let go," and spasm results. In gross lesions when the morbid process attacks the motor cells the spasm ceases and paralysis ensues. An analogous molecular change may account for the "paralytic" forms of writers' cramp. Molecular changes in the peripheral nerves, rarely if ever, cause spasm. The book is clearly written, and well printed, but unfortunately it lacks an index. P. C. K.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, NOVEMBER 18, 1886.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES, UPHAM & COMPANY,
283 WASHINGTON STREET, BOSTON, MASS.

MEDICAL EDUCATION IN THE UNITED STATES.

THE excellent work undertaken half a dozen years ago by the Illinois State Board of Health in the investigation into the requirements for entrance and graduation by the various medical schools of this country has had a fruition beyond the original aim of those who undertook it. The data, originally collected to serve as a basis for deciding what were colleges in "good standing" for the purpose of enrollment, according to the medical-practice requirements for the State of Illinois, have proved of value as standard statistics of the subject of medical education, and the publicity given to the reports has doubtless conduced toward a raising of the standards of institutions, which, but for this turning on of the light, would have been content with their former low grade of requirements. Primarily a police measure, the work has become an educational agency.

The latest report on this topic[1] brings the list of medical schools up to 252, from the 59 schools recorded in the first report. One hundred and twenty-three of these schools have succumbed to *tempus edax rerum*. But time itself has not so sharp a tooth against weak and incompetent medical schools as has the Illinois State Board, which is now supported by those of several other States — among them Minnesota, Missouri, and Iowa — and as a third of the new medical graduates yearly settle in the Western States, the sentry-work done by these organizations is especially useful.

The schedule of Minimum Requirements now in force for admission to all schools which are held "in good standing" includes a thorough examination in English branches, including mathematics, English composition and elementary physics, and natural philosophy. A minimum length of curriculum is two terms, of twenty weeks each. Quizzes or examinations, at least twice weekly, are required, with final tests in ten recognized departments of medicine, among them hygiene and State Medicine. Dissection is obligatory during two courses, and the entire period of study, prior to receiving a degree, must be not less than three years. While these provisions are somewhat less stringent than those of the American Medical College Association, they have the advantage of applying to all schools of medicine, and have been successfully enforced for three years.

As showing the increasing extent to which the Schedule is complied with, the following comparisons are of interest: Of the 129 colleges now in existence, there are 114 which exact an educational requirement as a condition of matriculation; in 1880 there were only 45. Attendance on three or more lecture-courses before graduation is now required by 41 colleges, as against 22 heretofore; and provision is made for a three or four years' graded course by 48 others. Hygiene is now taught in 110 colleges, and medical jurisprudence in the same number, as against 42 and 61, respectively, heretofore. The average duration of lecture terms has increased from 23.5 weeks to 24.8; 9 more colleges have lecture terms of five months or over, and 13 more have terms of six months or over, as compared with the sessions of 1882–83. These changes have all been made in the medical colleges of the United States, no material alteration in the Canadian schools having taken place in these respects.

A part of the report of considerable interest is that which covers the ratio of increase numerically and proportionally in the profession. In 1880, there were, according to the National census, 83,436 physicians in the United States. Since that date there have been added — exclusive of the foreign increment — 23,531 new graduates, not including those of the last session, 1885–1886. This makes a total of 106,947, and is an annual increase of over five and one-half per cent., while the annual increase of population is less than two per cent.

As might be expected, this proportional increase in the numbers entering the ranks of the profession is attended not only by close competition, but by a certain amount of downright failure. As shown by the figures for the State of Illinois, over seven per cent. of the entire number failed as physicians, and sought other modes of obtaining a livelihood. It is noteworthy, by the way, that non-graduates fall out in much larger proportion than the graduates, and that the graduates of three-course schools show the smallest percentage of loss, either by removal from the State, or by abandonment of practice.

The rate at which some of these superfluous men fall out of the ranks is shown for Chicago, thus: In 1880, there were certificates issued to 172 new-comers; five years later, only 84 of these remained — a loss of over one-half. In 1881 there were 183, in 1882, 171; in 1883, 200, and in 1884, 198 new-comers; and in 1885, there remained of each year's group, 97, 116, 145, and 168, respectively. In one year the loss was 15 per cent.; in two years, 30 per cent.; in three years, 32 per cent.; in four years, 47 per cent.; and in five years, over 51 per cent.

[1] "Medical Education and Medical Colleges in the United States and Canada," 1765-1886. Illinois State Board of Health, Springfield, Ill., 1886.

While there are estimated to be in the State of Illinois from 1,500 to 2,000 physicians more than are necessary to supply the legitimate demand for professional services, and probably an equal proportion in other States, it is gratifying to learn the conclusion drawn from the wide personal experience of the author of this report, whose official position has, during the past nine years, made him familiar with the professional history and status of over 13,000 men, more or less directly connected with the practice of medicine in Illinois. He has followed up, with especial interest and care, the careers of 789 out of 1,000 physicians who studied four years, and attended three terms before graduating. "These are," he says, "with a few exceptions, the successful and prominent members of the profession in the different communities in which they reside. They are well equipped by general education, by an ample period of professional study, by didatic and clinical instruction, and by hospital practice. They are successful, as a rule, because they have fitted themselves to command success."

SANDALWOOD OIL AS AN ANTI-BLENNORRHAGIC.

ACCORDING to Jaccoud's *Dictionaire Pratique*, that which renders the sandalwood oil valuable, outside of the rapidity and efficacy of its action as a blennorrhagic is that the drug, far from producing upon the stomach and upon the urinary passages the unpleasant effects of copaiba, is perfectly inoffensive and even agreeable, . . . in place of fatiguing the stomach and occasioning regurgitation . . . it stimulates the digestion and possesses a stomachic action without provoking any trouble of the digestive functions. Elimination by the skin never causes an exanthem, and the author of the article adds to these negative virtues very positive attributes in most diseases of the urethra and bladder, so that one is reminded of the historical writers of his boyhood in which the hero of the story is possessed of an unfailing perfection and his enemies of equally great failings.

In the *Annals of Surgery* of a year ago, was an article which extolled the drug in epididymitis, and mentions its value in gonorrhœal rheumatism. At the recent meeting of the Society for Internal Medicine in Berlin, a paper on the drug was read by Dr. Posner, and debated by several gentlemen, in which valuable properties were ascribed to the drug in cases in which injections were improper, namely, those in which the disease manifested its passage beyond the compressor urethræ muscle by inflammation of some of the adjacent organs, as the prostate, bladder, or testicle. It seemed to be the opinion that under all circumstances sandal oil was better borne than the other balsamics.

The report of Posner and the discussion, calls out a broadside from Dr. Letzel, of Munich, who makes a very genuine addition to our knowledge of the drug.

Dr. Letzel reports, from his clinic for skin diseases and syphilis, an abundant and carefully observed series of cases in which sandal oil has been administered for gonorrhœa or some of its complications.

During less than a year past Letzel has used sandalwood oil on gonorrhœal patients ninety-seven times. The drug was given at first in an emulsion with burnt coffee and cinnamon water, but patients had such an aversion to the mixture that capsules were substituted. Decided disturbances in the digestive tract occurred in four out of the ninety-seven patients, twice decided diarrhœa, and twice severe dyspepsia which lasted many days. Burdensome eructations, oppression and burning in the stomach, and a marked feeling of thirst were often noticed, but of transient nature which did not necessitate the abandonment of the drug. Five times occurred congestive pain in the region of the kidney, which reached such intensity in two cases that the subcutaneous use of morphine was necessary. Letzel then quotes from the second edition of Jullien to the effect that many patients complain of a painful sensation which occurs thirty to forty-five minutes after the injection of the remedy and radiates through the loins and even to the testicles, and that there is no trouble to which sandal oil gives rise more frequently than this congestive pains in the lumbar region. Jullien describes also an erythema from the drug, probably the only reported eruption from sandal oil.

Letzel sums up his experience in the following conclusions:

In the beginning of a gonorrhœa sandalwood oil influences the secretion in such a manner that after a few days the discharge becomes decidedly less, and instead of a greenish-yellow color appears only somewhat milky. The pain in urination and erection decrease faster than by indifferent treatment, and disappear freely in a few days. Of forty-two cases so treated, thirty-seven were influenced in the manner noted. In the seven remaining cases the influence of the sandal oil on the gonorrhœa was not noticeable.

If after ten to twelve days the use of the oil is abandoned the disease grows worse in most cases. The use of sandalwood oil gave the best results when it was begun in the third or fourth week of the disease, and when accompanied by a slightly astringent injection. Three out of twenty cases of this class healed without any injection in two to three weeks. In twenty-one cases out of twenty-nine, the excretion disappeared within eight to twelve days and were ended with an injection. Eight patients in whom a favorable result was not reached were indolent careless tramps.

In gonorrhœal cystitis and prostatitis the exhibition of sandal oil was of great use in all cases. The length of the affection was decidedly shortened and the suffering greatly diminished.

Chronic gonorrhœa was not noticeably influenced by the drug alone though local medication seemed to act more favorably with simultaneous internal administration of the oil.

"All in all, sandalwood oil modifies the secretion with decidedly greater promptness and surety than the other balsams, but the stomach does not endure the drug so lightly as most authors are inclined to believe, and further, the eventually occurring congestive condition of the kidneys warns us to greater care, and the last greatest defect in the drug is its too great expense."

MEDICAL NOTES.

— An order has been issued in Lower Austria forbidding manufacturers and tradesmen to sell nickel-plated vessels for cooking. It is stated that vinegar and other substances dissolve nickel; and that this, in doses of the seventh of a grain, produces vomiting, and is generally more poisonous than copper.

— Professor Ludwig Bandl, of Vienna, has been appointed Professor of Obstetries and Gynæcology at the University of Prague, to succeed Professor A. Breisky, who has been called to Vienna, to occupy the chair vacated by the retirement, through ill health, of Professor Spaeth.

— In view of the prevalence of cholera at Pesth, Trieste, and other places, the Local Government Board of England, have issued an order prohibiting, until April 1st, 1887, the importation into this country of rags from Austria-Hungary. The Board have also extended until April 1st, 1887, the prohibition of the importation of rags from Italy.

— A German, according to an exchange, had run up a large doctor's bill and called to see the physician concerning it, whereupon the following conversation ensued: "Goot-mornin', dogtor.', "Good-morning, Mr. Mozenthal. How is your family?" "Pretty vell; I gome to ask you sometings aboudt mein bill." "Yes?" with animation. "I don'd haf got mooch money, I vants to know vill you tage id oudt in der trade?" "I guess we can arrange that" (cheerfully). "What's your business?" "Vell — I blay me a leedle on dot trambone; undt I seranadt you more as twendy times!"

— Having found that the compound licorice powder produced very severe griping in many instances where he had ordered it, the griping being particularly severe in some of his younger patients, Dr. Martin Oxley (*Lancet*), has ordered the following formula for some time past, in which anise fruit is substituted instead of the fennel, and one-fourth part of ginger is added. The altered formula runs thus — senna and licorice-root, of each two parts; anise fruit and sulphur, of each 1 part; sugar, 5¾ parts; ginger, ¼ part. This altered preparation is quite as satisfactory in its laxative properties, is less liable to gripe, and is as pleasant to take as the officinal powder, and he would suggest its trial in cases where the powder as now prepared produces the disagreeable effects to which he has referred.

— A curious experience is related in the *Medical and Surgical Reporter*, of Dr. Robert St. George Dryanforth, of Washington. While serving in the War of the Rebellion, the doctor was shot through the lungs and invalided. He subsequently went to Europe for his health, and remained there for some years. When the German war broke out, he became correspondent for the *New York Tribune*, and in one of the battles he was shot through the base of the skull. He caught a heavy cold while lying wounded on the battle-field, and his wound in the lungs troubled him so much that his life was despaired of, and he was considered a victim of rapid consumption. One day during a violent fit of coughing the doctor brought up a piece of his overcoat, which had been shot into his lungs ten years before. The ejection of this cause of irritation so relieved him that he at once became better, and finally completely recovered. He returned to Washington, and has since held the office of Judge of the Court of Appeals. He was also a member of the Board of Examiners, and Assistant Commissioner of Patents.

— *The Medical Press and Circular*, Sept. 8, 1886, vouches for the truthfulness of the following: "A certain operator proposed to remove 'the uterine appendages' from a patient under his care, and he asked a gentleman present if he would like to examine the patient, saying she had been suffering for years with an acute pain, that life was a burden, etc. The gentleman, struck by the full, round, rosy cheeks and red lips of the woman, first asked her how she slept at night. 'Oh, very well, thank you,' was the reply. 'You have no pain at night, then?' was the next question. 'Oh, no,' she answered. 'Have you pain all day long?' continued the questioner. 'Not all the day through,' she replied. 'Have you pain every day?' he went on. 'No, not every day,' was the answer. 'How often does the pain come on, then?' the gentleman continued. 'Oh, three or four days a month,' was the innocent reply, much to the amazement of the questioner. The would-be operator was heard to mutter something about 'getting any answer you like,' but it will be satisfactory to learn that the patient saved her ovaries on that occasion, at least."

— The eminent surgeon, Professor Billroth, of Vienna, has joined the number of German professors who have lately spoken of the necessity of stricter supervision of the university students. He writes, with particular reference to students of medicine: "Sad experiences and observations naturally suggest the thought that our young men are not ripe for the degree of freedom prevailing in our universities. It is to be hoped that by tightening the pedagogic reins some improvement may be effected; the protest of the apostles of freedom surely ought not to be heeded. I would not favor a daily roll-call, but if, for instance, every clinical student had to appear four times instead of once at the practical demonstrations, and should mercilessly lose a semester by his absence when called out of turn, perhaps the students would attend the clinical lectures more frequently." He urges, before all, stricter pedagogic measures on the part of the

parents, saying: "We have overrated the average capacity of our students, their ethical force, and strength of character. A continuance of the present state of affairs would be perfectly unjustifiable."

— The propriety of adding salicylic acid to beer as a preservative is, we learn from the *British Medical Journal*, much discussed in Paris at the present time. The beers incriminated are principally of Bavarian origin; and the outcry, whatever may be the justice of the allegations, looks suspiciously like a determined attempt on the part of the influential wine-interest to hamper the import and sale of these foreign drinks, the annually increasing consumption of which has long been a thorn in its side. The addition of salicylic acid to milk is considered an adulteration, less, possibly, on account of its physiological effect than because it enables the dairyman and milk-factor to relax to some extent the extreme precautions of cleanliness otherwise necessary to keep the milk fresh and sweet. The injurious effects alleged to result from the ingestion of salicylic acid in beer have not been demonstrated with legal exactness, but it may, nevertheless, be condemned as an unnecessary and possibly hurtful ingredient. The subject has also been under discussion in Germany, with the curious and instructive result that the addition to beers for exportation has been authorized, but forbidden in beers destined for home use. This is a striking departure from the very excellent maxim about doing unto others as we would have others do unto us, and justifies to some extent the rigorous measures which it is proposed to take in regard to such beers in France.

NEW YORK.

— Dr. Samuel M. Fisk, a prominent physician of Brooklyn, Eastern District, and an inspector for the Brooklyn Health Department, died suddenly of apoplexy at his residence, on November 10th.

— The increase of measles has become more noticeable during the last two weeks. In the last week of October there were reported 162 cases, with 17 deaths, and in the week ending November 13, 288 cases and 43 deaths. Diphtheria is also prevailing to some extent in the tenement-house districts, and out of 79 cases reported in the last week of October, there were 48 deaths. During the week ending November 6, there were reported 83 cases and 32 deaths; during that ending November 13, 117 cases and 47 deaths.

— Dr. Cyrus Edson, of the Health Department, has seized and condemned 5,280 gallons of wine at a factory in the lower part of the city, and asked the authority of the Board for its destruction. He reports that the wine is made by macerating low grades of dried fruits in water, fermenting the product, and then adding four or five grains of salicylic acid to the pint as a preservative. Dr. Edson believes the wine to be deleterious to health, in which opinion he is supported by other officials of the Board; and the matter has been referred to the Counsel for the Department and the Sanitary Superintendent.

Miscellany.

SOME VITAL STATISTICS OF GRADUATES OF HARVARD.

AT the recent Harvard Festival, a small pamphlet was distributed, prepared by W. H. Tillinghast, editor of the Quinquennial Catalogue, and revised to the present date, which presents some facts of interest to the student of vital statistics.

The oldest surviving graduates are William Perry, M.D., of Exeter, N. H., born December 20, 1788; William R. Sever, of Plymouth, Mass., born May 30, 1791,— both of the Class of 1811, graduated seventy-five years ago.

The Classes of 1812, 1814, 1816, have no living members; those of 1813, 1815, have each one; that of 1817 has five. The first class in which the number of survivors is in excess of the deceased is that of 1841, the figures being respectively 25 and 21.

The percentage of deaths in the Classes from 1811 to 1880, arranged in ten year groups, is as follows:

Classes.	Per Cent.	Classes.	Per Cent.
1811-1820	97	1851-1860	28
1821-1830	87	1861-1870	16
1831-1840	59	1871-1880	6
1841-1850	41		

The percentage of deaths in the total number of graduates having been calculated for several of the schools, is thus compared with the same ratio for the College for the same length of time:—

Of the graduates of the Medical School, 30.7 per cent. are deceased; of the College, for 1791–1886, 38.9 per cent. Of the graduates of the Divinity School, 43.5 per cent. are deceased; of the College, 1820–1886, 25.7 per cent. Of the graduates of the Law School, 17.05 per cent. are deceased; of the College, for 1823–1886, 23 per cent. Of all who have received honorary degrees, 83.79 per cent. are deceased. Of all graduates of the College since 1642, 51.78 per cent. are deceased.

The average age of deceased graduates, from 1883–86, is as follows: the College, 58.4; Law School, 50.9; Medical School, 57.3; Divinity School, 64.9.

CHOREA CURED BY GYMNASTIC EXERCISES DURING HYPNOTISM.

THE *Practitioner*, October, 1886, gives a very careful and detailed account of a case of chorea in an Italian girl aged twelve, published by Dr. Riccardo Pari in *Lo Sperimentale*, July, 1886, lviii. 77–83. When it came under his notice it was not otherwise remarkable except that it had lasted for four years. It came on after a sharp attack of scarlet fever, and there was no accompanying rheumatism or hysteria of any sort. Careful hygiene had been kept up, and the treatment of electricity, tonics, and arsenic fully tried. When examined in October, 1885, there was no anæmia, no cardiac abnormality nor other morbid physical signs beyond moderately severe bilateral chorea. In recent medicine there are some cases of chorea cured by suggestion in hypnotism, and this was first tried by Dr. Pari. The girl was hypnotised by making her gaze fixedly at something in her hand, and it was strongly urged upon her when she was in the hypnotic condition that she should have no more chorea. Two such attempts

had no success, which was ascribed partly to her distrust in all methods of cure after her long experience. Then it was remembered how useful gymnastics had been in the cases of Hasse, and at the third hypnotic sitting this idea was taken up, and she was ordered to hold her arm out and keep it still. There was slight tremor after six or seven minutes (when the muscles in a normal state generally begin to grow exhausted), but she was ordered to keep it still, and succeeded in doing so for much longer. In subsequent sittings she obeyed orders to keep both arms outstretched for a quarter of an hour without tremor, to walk quietly, to stand still in all varieties of position, first on one leg, then on the other, etc. Between the sittings there was gradual improvement, and after twenty of them she was quite well.

PERITYPHLITIC ABSCESS DISCHARGING SPONTANEOUSLY AT THE UMBILICUS.

In the *Practitioner* (October, 1886), is recorded the following interesting case by Mr. William Pugin Thornton, M.R.C.S.:

"Early on the morning of August 1st, 1884, I was called to see a youth. He was slightly made, but very tall for his age. Lying on a bed, his face covered with perspiration, his body and limbs were cold, and his knees drawn up, and evidently he was in great pain. He was constantly sick, vomiting an almost stercoraceous fluid. The abdomen was tense and tender to the touch, especially in the right hypogastrium. His temperature was not very high, but having lost the record of the temperature I am unable to give any in connection with this case.

"The account given me was that for a week he had been over-worked, being at his office from 9 A.M., to 9.30 P.M. He then took a day's holiday, walking about twenty miles, and eating very little during the day except some hard apples. On reaching home late in the evening he had a substantial dinner, and went to bed shortly after. He slept through the night, but felt tired the next morning, and had little appetite throughout the day. He went to bed at 10, P.M., and slept till midnight, when he woke up with pain in the abdomen round about the navel; being sick and the pain increasing he called the servant up, who put hot flannels on him, and obtaining relief he fell asleep till 7, A.M. He then woke with intense pain, and was sick about every half hour. I saw him at 8, A.M., and again at 11, A.M., with my partner, Mr. T. Whitehead Reid. We could come to no accurate conclusions. Later on some of the symptoms pointed to typhoid, but taken altogether they did not satisfy us it was that disease. We treated the acute symptoms, sickness and pain, and on hearing the account of apples eaten on an empty stomach we gave castor oil with tincture of opium.

Nine days after it was evident that there was a collection of pus in the right hypogastric region. My partner and I considered the advisability of opening the abdomen. In the middle of the night (the 10th), the patient was alarmed by a gush of fluid through the navel. This proved to be pus, and the discharge continued through the night. In the morning I pressed out from a pint and a half to two pints. After a time he learnt to pass a catheter through the umbilical wound, and to syringe out the abscess cavity with Condy's fluid. The catheter disappeared a distance of nine inches."

On September 18th, the visits to the patient were given up and shortly after he went away. On November 6th an umbilical fistula, three inches deep, was all that remained. At Christmas time the wound was healed.

It would seem that in this case there was ulceration through the appendix vermiformis, followed by a deep abdominal abscess, and that it belonged to one of the interesting class which Dr. Fenwick mentioned in his Clinical Lectures at the London Hospital, published in the *Lancet* in December, 1884.

OBITUARY. — PAUL BERT.

M. Paul Bert, the statesman and scientist, died in Paris, November 11. Born at Auxerre, October 17, 1833, he lost his mother when a child and was brought up by his father, who was the son of a serf on the church lands of Auxerre, whom the revolutionists emancipated. He received a collegiate education and early developed an inclination toward the sciences. He entered Sainte-Barbe with the intention of preparing himself for admission to the Polytechnic at Paris, but owing to a change in circumstances, altered his plans, applied himself to the study of law, and received a license to practice. He then relinquished the law for the study of medicine. Licensed in 1863 as doctor of medicine and as doctor of sciences in 1866, he was made instructor in zoology to the faculty of sciences at Bordeaux in place of M. Flourens, and in 1868 he succeeded the celebrated M. Claude Bernard at the Sorbonne.

Among the earlier scientific works of Paul Bert were experiments with the physiology of breathing at high altitudes, and discoveries then new, now commonly known, as to the nature of asphyxia and the rôle of oxygen were made by him. The first thesis of M. Bert on animal grafting, won for him in 1865 the prize of experimental physiology. The result of his researches on the atmosphere was published under the title of "La Pression Barométrique." For this he was awarded the grand biennial prize of the French Institute. Like some other men distinguished in science, M. Bert developed a taste for political life. After the downfall of Napoleon III, in 1870, M. Bert was at first secretary of the prefecture, and then perfect of Yvonne, his native department. He was elected to the National Assembly in 1872, continuing its member for ten years or more. Politically he was an ultra radical, and evinced hostility to monarchs, monarchists and Catholics. Gambetta made him minister of instruction in the cabinet of 1881–82. In April, 1878, he was elected a member of the Academy of Sciences, and in January of the present year he was appointed to the post of minister resident of France at Hué, the capital of Annam. Among his scientific works are "De la Greffe Animale," published in 1863; "Revue de Travaux d'Anatomie et de Physiologie," published in 1864-66; "Notes d'Anatomie et de Physiologie Comparé," 1867-70; "Recherches sur la Mouvement de la Sensitif," 1867-70; "Leçon sur la Physiologie Comparée de la Respiration," 1869; "La Pression Barométrique"; "Recherches de Physiologie Expérimentale," 1879. Beside this, for many years he furnished the "Feuilleton Scientifique" for M. Gambetta's journal, the République Française. M. Bert's embassy to Tonquin which he undertook in the hope of adjusting the somewhat complicated diplomatic relations of the Republic with China, is understood to have been in its results somewhat of a disappointment to him.

Correspondence.

ABORTION OF FELONS. WRINKLES, NEW AND OLD.

NEW YORK, November 13, 1886.
18 West 30th St.

MR. EDITOR, — My father was a medical man, who graduated from the University of Pennsylvania in 1816 or 1817. In 1839, I learned from him that a felon could, if seen early enough, be made to abort by wrapping the finger-end with narrow strips of adhesive plaster.

When pus has been formed, I learned twenty years ago,

from a country doctor, that immediate relief and speedy cure would follow the gentle, slow separation of the nail from its envelope by means of a pen-knife blade, not too sharp, at the point nearest the seat of greatest pain. Very soon a drop of pus shows itself, and relief comes.

I am aware that the plan described is known to many medical men. It was not known to me at the time referred to, when the country doctor showed me how to treat a paronychious patient, whose finger I was about to lay open by the "free incision down to the bone," taught in the lessons of my great masters.

What a lot of valuable information a man decently furnished with humility can learn from our "one-horse-shay" brethren, who practice and *do their own thinking*, far removed from Poly- or Molly-clinics, and proximity to big batteries of consultation celebrities! And what a pity that so much of the knowledge they have slowly and painfully acquired should die with them!

In such intercourse as consultation practice brings me, I have been much impressed by the small number of medical men who know or practise Fuller's system of prescribing, enabling us to do away with the "uncertain, coy, and hard-to-please" vials, from which medicines are directed in *drop* doses. Have you not in your mind's eye, a blear-eyed Sairey or Betsey, of the Gamp or Prig family, as she endeavors to give three drops of tincture of aconite root, by the light of a poor tallow candle, or poorer oil-lamp, "every three hours?" It is needless to insist upon the difference between a drop and a minim; nor is it less so to say what different potency the same tincture (by name) has, according to its age, evaporation, or primary value.

Not long ago, in writing to an old pupil, now a prominent physician of the Pacific slope, I recommended Fuller's tablet triturates. In reply, he said, "What are they? none of our apothecaries know about them."

Just here, in my note to you, my mail-box gives me a letter from an old graduate of the University of Pennsylvania, to whom I had sent a small pocket-case of tablets, containing the medicines most often needed in general practice. The letter was one of thanks for the "new wrinkle," and gave me the following piece of personal history: "Some years ago, I went into a drug store, and told the man to give me a dose of salts, with twenty drops of laudanum in it. I was suffering from dysentery. So far as the epsom salt went, the prescription was all right, but he dropped the opiate tincture from *a gallon bottle*. I swallowed the dose, went home, and went to sleep, and *it took twelve hours to wake me up*. The family thought I was poisoned, and if I had died, the boys would have killed that druggist, *sure*."

I am well aware how many of our brethren confine their medical reading to the text-book published when they were students — in one case, in the year 1835 — and to what they can gleam from periodicals of the day. In that loyal legion there may be one or two, who, turning over the leaves of your excellent weekly, can find something new or useful in what I have written you. The abolition of tinctures and fluid extracts, when possible, would be a great emancipation for us doctors, who live and work without a trade-mark. Very truly yours, J. T. M.

DISLOCATION OF THE RIBS.

BOSTON, 138 Boylston St., Nov. 12th, 1886.

MR. EDITOR,—In the JOURNAL for Nov. 11th, 1886, is a very interesting account of the traumatic dislocation of the ribs, by Dr. W. C. B. Fifield. After referring to the rarity of this injury, Dr. Fifield says: "I could find no allusion to this accident except in one of the volumes of external pathology, by Barnes, and some person associated with him. . . . I certainly have not ever seen it in the best works of English surgery. I find not the slightest allusion to any such accident."

At a meeting of the Boston Society for Medical Observation I had the honor to report one case of similar character to that here mentioned by Dr. Fifield. The patient was a man who was injured by the effect of a sudden and unexpected great strain upon the extended arms, from weight, one end of which he was carrying. The sternal ends of the two upper ribs were dislocated forward upon the sternum, and the sternal end of the clavicle was also dislocated forwards into the interclavicular notch. I at that time collected all the well-authenticated cases of which I could learn, some five in number, and tabulated the character of the injuries with their causes.

This particular class of dislocations, as Dr. Fifield truly says is very rare, but the case he reports in the JOURNAL is not entirely unique, as the reading of his description would seem to indicate, for besides my own case above spoken of, there are no less than four other recorded instances of this injury, affecting a variable number of ribs, all of which are undoubtedly authentic. I am led to call attention to the facts in the case from the lack of mention in many standard works of surgery, of the cases now known, and the apparent need of again alluding to the really undoubted instances of this very rare lesion. The case reported from my own practice, together with those collected from other sources is published in the *New York Medical Journal* in the issue for July 14th, and July 21st, 1883.

Yours respectfully,
ALBERT N. BLODGETT, M.D.

A CURE FOR NEURALGIA.

EVERETT, Mass., November, 1886.

MR. EDITOR, — The experience of over fifty years in the practice of medicine ought to enable a person to give some facts or opinions that might be of service to the younger members of the profession. Judging from the various remedies and their combinations, prescribed for pure neuralgia, it must be a difficult as well as a perplexing disease to treat.

As the medication that I have used has been efficacious in my hands, it seems worthy of publicity.

R	Tinct. Cinchona Comp.	ʒ ij.
	Tinct. Nuces Vom.	ʒ ss.
	Morphiæ Sulph.	grs. ij
M.	Dose, one teaspoonful every three hours.	

This may be varied according to the susceptibility of the patient. It may be thought incredible, yet nevertheless, it is true, that I have never seen a case of pure neuralgia that it would not cure.

The following case may have some influence in convincing the profession of the efficacy of the medicine. A gentleman from Massachusetts came into my office in New York city, and introduced himself by saying that he had come to see me because he promised a friend that he would; and that he expected that I could benefit him. After examining him I said that his difficulty appeared to be simple neuralgia, and that I had never seen a case that I could not cure. He thought his would prove an exception.

To convince me of the gravity of his disease, he said that he had suffered from it for five years, four years in this country and one while absent in Europe for treatment. For the first six months while absent, he was under Brown-Séquard's care without any benefit. He then went to Paris and consulted Nélaton, but he was equally unsuccessful. From Paris he went to Vienna, and returned home after a year's trial, no better than when he left.

I prescribed for him. After two weeks, he wrote me saying, "your first prescription cured me, you hit the nail on the head the first time." This must be considered a strong case and one that had tested the skill of a large number of eminent physicians, both in this country and in Europe. I have other cases that had been treated for years in this country, without permanent relief.

I gave an old gentleman, who had given up all expectation of ever finding any relief, a small vial of medicine; on meeting him the next day, he joyfully remarked that he

had not had such a night's rest for years; that he slept quietly all night.

I will here remark that physicians should know the strength of the tinctures prescribed, as many of them are worthless. Yours very truly,

HENRY G. DAVIS, M.D.

REDUCTION OF COPPER IN FEHLING'S SOLUTION WITH CHLORAL HYDRATE.

WOODSTOCK, VT., November 12th, 1886.

MR. EDITOR, — On applying Fehling's test to a specimen of urine sent to me for examination, I found the copper reduced as with diabetic urine, while the specific gravity was only 1015. On inquiry, I found that a few grains of chloral hydrate had been added to the urine to prevent decomposition. On further trial I found that a very weak solution of chloral hydrate in clear water would reduce the copper. I have since experimented with it in different solutions and varying strength, and always with the same results. In two cases, after the internal administration of medicinal doses of chloral, the characteristic reaction was produced on testing the urine with the copper solution. Two days afterwards, the urine in neither case showed any signs of sugar.

The fact that chloral hydrate would reduce the copper solutions if added to urine, was new to me, and I think is not generally known. I do not remember seeing any mention of it in the text books or journals. Further investigation regarding the effect on the urine of the internal use of chloral is desirable. Very truly yours,

O. W. SHERWIN, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 6, 1886.

Deaths reported 2,298: under five years of age 833: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 421, consumption 320, lung diseases 277, diphtheria and croup 173, diarrhœal diseases 79, typhoid fever 59, measles 33, malarial fever 25, scarlet fever 23, whooping-cough 11, cerebro-spinal meningitis eight, puerperal fever seven. From scarlet fever, Cincinnati eight, New York five, Pittsburgh four, Brooklyn three, Philadelphia, Gloucester and Newburyport one each. From measles, New York 20, Cincinnati and Pittsburgh five each, Brooklyn one. From malarial fever, New York 10, New Orleans seven, Brooklyn and Charleston three each, Baltimore two. From whooping-cough, New York and Brooklyn three each, Boston, District of Columbia, Worcester, Springfield and Haverhill one each. From cerebro-spinal meningitis, New York three, Pittsburgh, Worcester, Lowell, Fall River and Northampton one each. From puerperal fever, New York two, Boston, Cincinnati, Pittsburgh and Springfield one each.

In the 22 cities and greater towns of Massachusetts, with a population of 1,018,514 (population of the State 1,941,465), the total death-rate for the week was 14.74 against 18.07 and 20.23 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,003,817, for the week ending October 23d the death-rate was 19.3. Deaths reported 3,371: infants under one year of age 909: acute diseases of the respiratory organs (London) 290, diarrhœa 183, scarlet fever 83, measles 56, fever 49, whooping-cough 35, diphtheria 32.

The death-rates ranged from 12.7 in Nottingham to 33.5 in Preston; Birkenhead 14.8; Birmingham 17.8; Hull 20.2; Leeds 21.5; Leicester 18.3; Liverpool 24.0; London 17.7; Manchester 24.5; Newcastle-on-Tyne 22.2; Sheffield 20.5; Sunderland 21.3.

In Edinburgh 18.0; Glasgow 21.7; Dublin 20.5.

The meteorological record for the week ending November 6, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps: —

Week ending Saturday, Nov. 6, 1886.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 6, 1886, TO NOVEMBER 12, 1886.

WRIGHT, J. P., major and surgeon. From Department of Texas to Department of Missouri, for duty as attending surgeon at Leavenworth Military Prison, Fort Leavenworth, Kan.

FORMARD, W. H., major and surgeon. From duty as attending surgeon headquarters, Division of the Missouri, and examiner of recruits at Chicago, Ill., to Department of Dakota.

HUBBARD, V. B., major and surgeon. From Department of Arizona to duty as attending surgeon at headquarters, Division of the Missouri, and as examiner of recruits at Chicago, Ill. S. O. 257, A. G. O., November 4, 1886.

LORING, L. Y., captain and assistant surgeon. Sick leave of absence further extended three months on surgeon's certificate of disability. To be relieved from duty in Department of California, and, on the expiration of his present sick leave of absence, will report by letter to the Surgeon General of the Army. S. O. 262, A. G. O., November 10, 1886.

MOSELEY, E. B., captain and assistant surgeon. Assigned to duty as attending surgeon in San Francisco, Cal. S. O. 94, Division of the Pacific, November 1, 1886.

PERLEY, HARRY O., captain and assistant surgeon. Granted leave of absence for four months on surgeon's certificate of disability. S. O. 257, A. G. O., November 4, 1886.

BARROWS, CHARLES C., first lieutenant and assistant surgeon. Ordered to report to commanding officer St. Francis Barracks, St. Augustine, Fla., for duty at Fort Marion. S. O. 180, Division of the Atlantic, November 10, 1886.

PHILLIPS, JNO. L., first lieutenant and assistant surgeon. Granted leave of absence for one month with permission to apply at headquarters, Division of the Missouri, for an extension of one month. S. O. 116, Department of Dakota, November 2, 1886.

EWING, CHARLES B., first lieutenant and assistant surgeon. Ordered from Fort Supply, Ind. Ter., to Fort Leavenworth, Kan., for duty. S. O. 126, Department of Missouri, November 6, 1886.

IVES, FRANCIS J., first lieutenant and assistant surgeon. Ordered to proceed to and take station at Fort D. A. Russell, Wyo. S. O. 145, Department of Platte, November 4, 1886.

PROMOTION.

O'REILLY, ROBERT M., captain and assistant surgeon. To be major and surgeon, November 1, 1886, *vice* Clements, deceased.

APPOINTMENTS.

CLENDENIN, PAUL, first lieutenant and assistant surgeon, November 5, 1886.

ANDERSON, CHARLES, L. G., first lieutenant and assistant surgeon, November 5, 1886.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDING NOVEMBER 6, 1886.

AMES, R. P. M., passed assistant surgeon. Relieved from duty at Marine Hospital, New York, to assume charge of Marine Hospital, Vineyard Haven, Mass., November 1, 1886.

URQUHART, F. M., passed assistant surgeon. To proceed to Norfolk, Va., for duty, November 4, 1886.

YEMANS, H. W., passed assistant surgeon. Relieved from duty at Marine Hospital, San Francisco, Cal., to assume charge of the Service at Galveston, Tex., November 1, 1886.

WASDIN, EUGENE, passed assistant surgeon. When relieved, to proceed to New York, for duty at Marine Hospital, November 1, 1886.

WILLIAMS, L. L., assistant surgeon. Relieved from duty at Marine Hospital, Wilmington, N.C., to proceed to Pittsburgh, Pa., for temporary duty, November 5, 1886.

PERRY, T. B., assistant surgeon. Relieved from duty at Marine Hospital, St. Louis, Mo., to proceed to San Francisco, Cal., for duty at Marine Hospital, November 1, 1886.

SOCIETY NOTICE.

GUILD OF S. LUKE.— There will be a meeting of the Guild of S. Luke, the Evangelist and Physician, at Calvary Chapel, 4th Avenue and 21st Street, New York City, at 12, M., Friday, November 19, 1886. At 2, P.M., a public service will be held in the chapel, to which physicians and medical students of the regular medical profession who are communicants of the Protestant Episcopal Church, and priests and deacons of the same, are cordially invited to be present. Addresses are expected concerning the objects and working of the Guild, by Bishop Quintard, of Tennessee, and others.

W. THORNTON PARKER, M.D., *Provost*,
Newport, R. I.

DEATHS.

Died in Portland, Me., November 12, 1886, Francis Patrick Scully, M.D., M.M.S.S., aged thirty-four years.

Died in Webster, Mass., November 8, 1886, Frederic Davis Brown, M.D., M.M.S S., aged sixty-two years.

BOOKS AND PAMPHLETS RECEIVED.

Meconeuropathia. By C. H. Hughes, M.D., St. Louis, Mo.

The Surgery of the Pancreas, as based upon Experiments and Clinical Researches. By N. Senn, M.D. (Reprint).

Fifty Cases of Abdominal Section. (Second Series). James B. Hunter, M.D. (Reprint).

Medical Education and Medical Colleges in the United States and Canada, 1765–1886. Illinois State Board of Health. Springfield, Ill.

Observations and suggestions in regard to the Method of Operating during the same Anæsthetization for Lacerations of the Cervix Uteri and Ruptured Perineum. By Thos. A. Ashby, M.D., Professor of Gynæcology in the Baltimore Polyclinic and Post-Graduate Medical College, etc. Baltimore: 1886.

The Curette as a Diagnostic and Therapeutic Agent in Gynæcology and Obstetrics. By B. Bernard Browne, M.D., Professor of Diseases of Women in the Woman's Medical College of Baltimore, etc. Baltimore: 1886. (Reprint.)

Hog Cholera. D. E. Salmon, Chief of the Bureau of Animal Industry: His Investigations into the Cause and Nature of Hog Cholera critically considered by Frank S. Billings, Director of the Patho-Biological Laboratory and Experiment Station of the University of the State of Nebraska.

Lecture.

TWO CASES OF MALIGNANT OR ULCERATIVE ENDOCARDITIS.

A CLINICAL LECTURE DELIVERED AT THE PHILADELPHIA HOSPITAL,

BY JOHN H. MUSSER, M.D.,
Physician to the Hospital, and Pathologist to the Presbyterian Hospital.

I HAVE here some specimens showing the lesions of malignant or ulcerative endocarditis as seen in a case recently in the wards of the hospital, and also some photographs of a case which came to my notice in the Presbyterian Hospital some time ago. I also have here the specimens from the latter case, and shall demonstrate to you as well as I can, the pathological lesions. In this heart there are seen on the leaflets of the mitral valve, a fringe of soft vegetations which were very friable when first removed, and in fact still are easily broken. They project into the ventricle and auricle, interfering seriously with the circulation. They are also seen on the aortic valves, and in this instance we find the rather rare occurrence of the lesions on the tricuspid and pulmonary valves. On microscopical examination of a teased preparation, these larger masses seemed to be made up of a granular substance in which were innumerable micrococci. In addition to this hyaline structureless appearance of the mass, a croupous or fibrinous exudation, cell proliferation was seen, with leucocytes in large numbers. The micrococci not only invested the proliferating membrane, but also dipped deeply into the lymph spaces of the neighboring structures looking not unlike the penetrating pegs of epithelioma. The smaller masses were less free from granular material and contained more of the cellular structure, and showed especially, old connective tissue elements most markedly. These proliferating structures while to a certain extent limited to the valves, are in this case also seen on the chordæ tendineæ, and on the wall of the heart itself, budding out from the endocardium.

In cases of malignant or ulcerative endocarditis, not only do we find these proliferative masses, but quite frequently we also find ulcerations with or without fungoid growths of inflammatory material. These ulcerations are found in the valve and in the heart muscle, and may lead to perforation. Microscopical examination of such ulcers shows abundant micrococci and the presence of round cells and granulation tissue. The ulceration may perforate the valve or the heart muscle itself, and lead to the development of aneurism, or to leakage from one cavity to another, or from the cavity of the heart into the pericardium, causing a fatal result. In addition to the fungous growths and these ulcerations, there are found in some instances, minute abscesses. The pus in these abscesses contains an abundance of micrococci.

In this second specimen the mitral valve is affected alone. The enormous degree of proliferation of the new growth can be readily seen. That on the anterior leaflet of the mitral valve projects into the ventricle, while that on the posterior leaflet projects into the auricle.

The presence of this granular material and the existence of micrococci in the new growths, would of necessity lead us to infer that the blood was infected, and such is the case. Microscopical examination shows abundance of micrococci floating free in the blood, and some are also found in the leucocytes. The infection of the blood and the presence of micrococci in these free situations where they can be readily disturbed by the blood current, lead us to expect structural changes in the peripheral circulation. By the force of the blood current, micrococci, cells and granular debris are carried into the distal circulation and form infarcts. When the disease is on the left side of the heart, these infarcts are seen in almost all parts of the arterial circulation; for instance, in the case recently under observation, there were innumerable infarcts in the skin, and nearly all the internal organs. Microscopical examination would show in addition to the hæmorrhage of the infarct, the presence of micrococci, occluding some minor capillary. The mucous membrane and the serous membranes may also be similarly affected in these cases. In this instance, infarcts were seen in the peritoneum and in the pericardium over the surface of the heart. The mucous membrane of the gastro-intestinal tract, showed numerous infarcts. The nature of these infarcts depends largely upon the nature of the primary infecting material. If there is an abundance of pus, they rapidly change into abscesses. In other instances, they remain as simple hæmorrhagic infarcts, and if the patient lives, undergo the changes usually seen after emboli. Here is a section of the intestine which shows the hæmorrhages in the mucous membrane. In this case, the most remarkable lesions were the number and extent of the infarcts in the stomach, particularly toward the cardiac end. In the first case, the only infarcts found were in the kidneys. There was also most marked glomerulo-nephritis. In the second case, the renal infarcts were not so large, but there were innumerable small ones in the capsule of the kidney, and microscopical examination would in all probability reveal the evidences of glomerulo-nephritis. The spleen, you observe, shows the infarcts very distinctly.

Not only are the lesions found in these structures, but capillary emboli may also occur in the brain. And not alone are the capillaries involved, but large plugs may be broken off and carried into the cerebral arteries, cutting off the circulation of a large portion of the brain structure producing hemiplegia and other grave cerebral symptoms. In the second case, a large thrombus had formed in the iliac artery, with obstruction to the blood supply of the lower extremity. It was evidently a recent formation, as it had produced no symptoms during life.

In addition to these changes which are noted in most cases of malignant endocarditis, namely, the changes in the structure of the valves; of the endocardium and of the heart muscle and changes in the blood, and secondarily, the presence of emboli and infarcts throughout the arterial circulation, there are often other lesions. For instance, in many cases the lesions of rheumatism or pneumonia or diphtheria are present. In other cases there are found in some portion of the body small abscesses, disease of the bones or some suppurative process. In such cases the endocarditis is secondary to the disease in the peripheral structures. Many cases, for instance, have been reported in which a pelvic abscess had been the primary origin of the disease. In the same way, in disease of the bone and in rapidly growing cancer which has undergone inflammatory changes, malignant endocarditis may develop.

These anatomical conditions have led to the division of the disease into three classes: First, those cases in which there are present only lesions of the heart and of the blood, and lesions due to emboli, are classed as cases of idiopathic or spontaneous malignant endocarditis; Second, those cases in which the lesions of rheumatism or pneumonia are found in addition, are classified simply as cases of associated malignant endocarditis; Third, those cases in which the disease is due to the presence of suppurative inflammation in the distal circulation or to a general septic process, are classified as cases of secondary malignant endocarditis.

By the knowledge of the anatomical characters of the disease, one can readily trace and keep well in mind the clinical history of these cases. First, from the fact that micrococci are found in the blood and in the inflamed structures, we should infer that there must be some general symptoms due to the septic process, and such is eminently the case. Second, the severe local cardiac lesion produces symptoms characteristic of obstruction in the orifices, while finally, the character of the primary lesion determines the presence and nature of the third class of symptoms, namely, those arising from peripheral infarcts and inflammations.

Cases of malignant endocarditis are characterized by rigors, irregular fevers and sweats, and by the occurrence in the later stages, of jaundice due to disorganization of the blood. There may also be vomiting and diarrhœa which examination shows is not dependent upon organic lesions of the stomach and bowels, but on the septic process. Enlargement of the spleen, another accompaniment of the septic process is also observed. The affection is sometimes accompanied by inflammation of the serous membranes, especially of the brain. Indeed, the only prominent symptoms of malignant endocarditis may be cerebral.

From the blood lesions, depending upon the extent to which the blood has become disordered and infected with the micrococci, and secondarily, upon the reaction of the structures to the micrococci in the blood, we have different types of the disease. Clinical experience has led us to divide the cases into four classes, the pyæmic, the typhoid, the cerebral and the cardiac. The pyæmic type, as its name indicates, resembles pyæmia in its symptoms and course. The cerebral type simulates inflammation of the meninges of the brain in its symptoms. Possibly without any symptoms referable to the heart, there will be pain in the head and in the back of the neck, with high fever, drowsiness, stupor, convulsions and coma. In the typhoid type, the symptoms simulate those of typhoid fever in many respects, the affection beginning with irregular chills, irregular fever, and being accompanied by profuse perspiration, emaciation, low muttering delirium, a dry, brown tongue, and even the occurrence of diarrhœa. In the cardiac form of the disease, the symptoms depend not so much upon the condition of the blood, as upon the primary cardiac lesions. While a healthy heart may undergo the changes which I have demonstrated to you, a diseased heart is much more likely to do so. In many cases of cardiac disease, the diseased structures seem to furnish a hot-bed for the development of the micrococci. More cases of malignant endocarditis are found in old cases of cardiac disease than in any other class. In the cardiac type, we have in addition to the symptoms referable to the heart, namely, dyspnœa, pain and distress about the præcordia, and palpitation,— also irregular fever and sweats.

The local symptoms due to the presence of this severe and extensive inflammation of the cardiac structure are pronounced and distressing. From the appearance of this enormous outgrowth on the mitral valve (second case), you can infer considerable obstruction to the blood-current, and hence the production of a murmur. So, in all cases, a murmur is heard at the orifice affected. Sometimes it is heard at several points, according to the diverse seat of the lesion. The murmur is usually strong and low in pitch. It may be systolic or diastolic. It is conducted or transmitted in accordance with the laws that govern murmurs, but differs in the variation of its character. From time to time it may be high or low pitched, loud or soft, strong or feeble, indeed, may temporarily disappear, such changes depending on the change of the outgrowths by loosening and floating off in the blood-stream. With the murmur, would arise other evidence of obstruction, such as dilatation of one or more of the chambers of the heart, with increase in the area of dulness and of impulse. Under these circumstances, the heart acts more violently, is likely to be irregular and very frequent, while palpitation and cardiac dyspnœa would be present.

Finally, we look to the nature of the central lesion for the character of the symptoms developed in the peripheral circulation. If largely purulent in character, the infarcts would rapidly be converted into abscesses. In most instances, simple hæmorrhagic infarcts are observed. In both, crococci abound.

The infarcts or capillary hæmorrhages are observed in the skin, the conjunctivæ, and the external mucous membranes. They are seen in the retina, and their presence in the gastro-intestinal or urinary tracts may be inferred from the occurrence of blood in the natural discharges, or of hæmorrhages from these localities. Their presence in the brain is determined by the phenomena common to cerebral emboli. In the skin, these infarcts are most abundant, and are distinguished by their bright red color and their persistence on pressure.

The case from which the first specimens were removed was a typical example of malignant endocarditis, and I shall ask your attention to the prominent points in its history: W. J.,[1] white, was admitted to the medical wards of the Presbyterian Hospital, October 3, 1884, suffering with rheumatism, localized in the left knee and the right shoulder and elbow. He stated that he had been feeling badly for some time, and had been losing flesh and strength. Previous to the recent illness he had had small-pox, syphilis, and gonorrhœa. The fever was very high, and out of proportion to the local symptoms. It was irregular, and at times there were profuse, exhausting sweats. This case was typical in its marked remissions and intermissions, the temperature sometimes going as high as 105°, and on one occasion, going as low as 96.5°. Some time after admission, the patient complained of pain about the præcordia, and, on examination, a murmur at the mitral valve was found. No particular stress was laid upon the cardiac trouble, which was regarded as a simple endocarditis, which often arises in the course of rheumatism. During the course of the rheumatism, he had, one month after admission, an attack of pneu-

[1] See Transactions College of Physicians of Philadelphia, 1886.

monia of the lower lobe of the right lung. The fever continued and the exhaustion became extreme, and finally, one day, after a chill, congestion of the lungs took place, and death resulted. The duration of the illness was sixty-eight days.

An interesting feature of this case was the development of malignant endocarditis in the course of rheumatism, and the occurrence, during the disease, of pneumonia.

Pneumonia is often a primary affection in this disease. Moreover, in those cases in which the right heart is affected, an infarct may form in the lung, causing pulmonary apoplexy and associate pneumonia, and such was possible in this case. Otherwise, it is not liable to complicate endocarditis.

The irregular fever, the exhaustive sweats, and the diarrhœa due to sepsis were marked. The cardiac murmur and the dyspnœa caused by the local lesion were present, but the occurrence of infarcts was not demonstrated during life. Such is a summary of the interesting clinical features observed.

The case from which the second specimens were removed was N. S., aged twenty-seven years, a German, who was admitted to my wards in this hospital, August 26, 1886. At the same time, her husband and children were admitted suffering with some febrile complaint, thought to be malarial. This is important, as indicating that the family were in straitened circumstances, and probably living in an unhealthy locality. The patient had been ill for six weeks with an irregular fever, said to be malarial. At this time she was nursing an infant one year of age. The labor had been natural, and she had a good getting up. Three years ago she had an attack of malarial fever, and at one time had rheumatism of the leg. She never had any other ailments, and was strong and hearty, and of temperate habits. The family history was good. The parents and several brothers and sisters are still living. One sister died of pneumonia; the cause of death of another is unknown.

On admission, it is noted that the patient is prostrated, and complained of chilly sensations and of nausea, and sweat profusely. The tongue was clean and moist. The bowels were loose, there being five movements in the twenty-four hours, the stools thin and greenish in color. The nausea disappeared in the course of twelve hours. There was some tenderness in the epigastrium, but none in the iliac fossa. The spleen extended in the axillary line, from the sixth rib to the margin of the ribs. There was no eruption. Both cheeks were flushed, the skin and mucous membranes were pale, the hands quite anæmic, and the body somewhat emaciated; the mind was clear. The lungs and heart were normal. A nutritious diet, with stimulants and quinia, were ordered. Five days later a cardiac murmur was detected. The general condition and symptoms were about the same. The apex-beat of the heart was in the fifth interspace, in the nipple line. The impulse was moderately feeble; there was no thrill. The pulmonary second sound was somewhat accentuated. A low-pitched, systolic murmur was heard at the apex, and transmitted into the axilla. There was no murmur at the aortic orifice. The pulse was rapid, small, and feeble. There was no cough nor dyspnœa. Ulcerative endocarditis was suspected.

September 8th. It is noted that the fever has continued, in spite of the use of quinine. There were profuse sweats during the day, but not at night. The anæmic appearance of the face was marked, and the patient was evidently losing flesh and strength. The diarrhœa continued. The cardiac murmur had increased in intensity, and could be loudly heard at the angles of both scapulæ, especially on the right side. There was marked tenderness on pressure, and some pain in the third left intercostal space. At the base of the right lung, impaired resonance and fine, moist, crepitant râles were observed. A few râles were also found at the right apex. There was short, high-pitched, jerking inspiration and prolonged expiration at the right apex, and high-pitched inspiration at the left.

September 12th. Two days ago, two small, purpuric spots were observed on both upper eyelids, and to-day, hæmorrhagic infarcts are seen all over the trunk and on the upper extremities, pin-head to split-pea size, bright red in color, not disappearing on pressure. Hæmorrhages in the bulbar and palpebral conjunctivæ of both eyes, at the inner and outer canthus, were also seen. The patient was rapidly losing flesh and strength, and the sweats continued. The abdomen was distended in the epigastric and umbilical region, and a large, wavy impulse was detected in the epigastrium. Nausea and vomiting had recurred during the past five days, and the diarrhœa continued. The spleen was tender, and could be readily felt below the margin of the ribs. The pulmonary signs had disappeared. There were no cerebral symptoms. The heart's action was irregular, and the pulse small, feeble, rapid, and dicrotic. In the second interspace to the left of the sternum, a perceptible thrill was present. The systolic murmur was not so loud at the apex as it had been. Over the third rib, a loud, booming, systolic murmur, with a "grinding" element, was heard. In the second interspace to the left of the sternum, there was heard a loud, rough, high-pitched murmur. The pulmonary second sound was muffled. The murmur over the tricuspid valve was not so distinct as over the mitral valve. There was no œdema, and the mind continued clear.

The day following there was a chill. The urine was scanty, high-colored, and contained blood and a small quantity of albumen. Blood and epithelial tube-casts were found in abundance. The chill was repeated the next day (14th). The patient was a little more drowsy, but there was no delirium. New capillary infarcts were seen about the neck. Infarcts also involved the lips and end of the tongue. The conjunctivæ were slightly icterode. For half an hour there was severe dyspnœa. The exhaustion increased, and the patient died in the early morning of September 15th.

I have here the temperature chart showing the course of the fever during the disease. As will be seen, there were marked remissions. Twice the temperature was above 105°, and on one occasion it reached 105.8°. At the same time the pulse was excessively rapid and feeble.

You will observe here again symptoms due to the general process, symptoms due to the local cardiac trouble, and symptoms due to the infarcts. The case presents a most typical example of the evolution of the clinical phenomena of malignant endocarditis.

It is of interest on account of the difficulty of diagnosis. It was at first thought possible that the case was one of malarial fever of a remittent type. The failure of large doses of quinia to control the fever, the appearance of the infarcts and the development of the cardiac murmur, led us very soon to abandon the idea

of malaria, and look upon the case as one of ulcerative endocarditis. Until the development of the hæmorrhagic infarcts in the skin and the occurrence of renal emboli there was not sufficient evidence to warrant a positive diagnosis, however. Typhoid fever was thought of. Many of the cases of malignant endocarditis which have not been regarded as cases of intermittent fever have been considered to be cases of typhoid fever. In this case there was diarrhœa, enlarged spleen, and the occurrence of fever with prostration. In other cases the typhoid symptoms are more marked than in our case, so that a mistake in diagnosis is readily made. In this case, as in most instances, the temperature was not characteristic of typhoid fever. In the latter disease, the temperature follows a certain regular course; further the abdominal symptoms are more marked than in ulcerative endocarditis, the lesions of the heart are absent, the pulse is not so frequent, the sweats are not so profuse, the hæmorrhagic infarcts are wanting, and the rose-colored spots characteristic of typhoid fever are found. By bearing these points in mind a mistake is not apt to be made. A mistake is most likely to be made in those cases of typhoid fever in which the temperature range is very irregular.

There are some cases in which typhoid fever occurs in a person who already has heart disease. This may obscure the diagnosis, but the uniform character of the murmur, the absence of capillary infarcts, the absence of jaundice and the presence of marked abdominal symptoms would lead us to a correct diagnosis. A point in the diagnosis of recent malignant endocarditis from long-standing heart disease complicating typhoid or intermittent fever is, moreover, the presence of either hypertrophy or dilatation in the latter case. You may not be able to differentiate the cases from the seat or the character of the murmur, but if these changes in the structure of the muscles were noticed, you would infer that the cardiac lesion was of long standing, and that a febrile affection had occurred in a subject of chronic heart disease.

At one time, before the cardiac symptoms appeared, it was thought that this might be a case of tuberculosis. The sweats, irregular fever, prostration and the occurrence of râles in the lungs pointed in this direction, but in our case, as in other cases of malignant endocarditis, there was wanting a symptom which is usually present in tuberculosis; that is, excessively rapid respiration. There was also absence of cause which is, however, not of much significance in acute miliary tuberculosis. The appearance of the cardiac symptoms and the peculiar range of temperature, led us to eliminate this affection.

I have already mentioned that malaria is often simulated by ulcerative endocarditis. Many cases treated as ague, have turned out to be instances of the pyæmic variety of malignant endocarditis. The presence of the germ of Laverran in the blood, would at once confirm the diagnosis of ague, or the presence of pigment in the blood and tissues would point to malaria. The cases are sometimes very difficult to settle, and due attention must be paid to their minor details.

Where a murmur develops in the course of articular rheumatism, it is sometimes difficult to decide whether it is due to a septic process or to a simple endocarditis which frequently complicates rheumatic affections. If in the course of rheumatism ulcerative endocarditis sets in, the temperature will be out of proportion to the rheumatic manifestations. The physical signs differ from those of simple endocarditis. In the latter there is a soft, blowing, low-pitched murmur which is not so widely transmitted as in the former. The murmer of simple endocarditis is persistent and of one character continually, while the murmur of malignant endocarditis varies in seat and in intensity from day to day. One day it may appear to be limited to the mitral valve, the next day, to the aortic valve. This variation depends upon the amount of exudation present, and whether or not it is set free in the course of the disease. If a large mass of vegetation disappears from the valve, the symptoms will change in character. This is not the case in simple endocarditis. Bearing in mind this difference, and remembering that in simple endocarditis, infarcts do not occur, that jaundice does not develop, and that the spleen does not become enlarged, the differential diagnosis can usually be made.

The case which I now bring before you is one of rheumatism extending over a long period of time, and presenting some features which might lead one to infer the occurrence of malignant endocarditis, but there are some other features which negative that idea entirely. The points suggesting malignant endocarditis are the irregular temperature, as is seen from the chart, the long continuance of the case, the frequent exacerbations after a short period of normal temperature and the presence of cardiac lesion. There are, however, two or three points which are in opposition to this view. In the first place, each exacerbation of fever occurred at a time when there was a fresh attack of joint pain. During the past two weeks, the joint symptoms have been limited to the knee, and have not been very marked. The pain complained of is, I think, at present largely of an hysterical nature. The patient has been under observation six weeks. There is present a murmur which during the whole time that the patient has been under observation has not changed its character. The murmur is limited to the mitral valve, is low pitched and soft and blowing in character. These are the characters of the murmur of recent endocarditis. Moreover, the murmur is not accompanied by the profound disturbance of circulation that is found in cases of malignant endocarditis where there are large vegetations projecting into the lumen of the valves.

A method of differential diagnosis which might be of value has not been referred to. Capillary hæmorrhages are known to occur in the fundus of the eye before they appear in the superficial structures, and an examination of the eye-ground would therefore be of great service in the recognition of endocarditis.

The prognosis of malignant endocarditis is, of course, extremely grave. There are some cases which are said to have recovered, but in these cases, there is an element of doubt. It seems impossible that a mistake could be made where the local cardiac trouble, with the infarcts and the pyæmic symptoms are present. The reason that the disease has not been oftener diagnosticated is because it has not been suspected.

The treatment, as will be inferred from my remarks, is unsatisfactory. In the large number of cases it can only consist in the treatment of symptoms. The presence of micrococci in this disease has only recently been demonstrated, and its septic character shown. Remedies to counteract the septic process have been administered. One case has recently been reported by Dr. Samson, in which the administration of sul-

pho-carbolate of soda in thirty grain doses three times a day, had been followed by cure of the patient. Apart from the administration of the sulpho-carbolates, the use of carbolic acid and the bichloride of mercura in minute doses I believe would be valuable. Stimulants and iron in large doses, if the stomach will bear it, are indicated. It is, however, usually not possible to give iron, on account of the vomiting. The treatment of the pyrexia also requires attention. In our patient it seemed that the administration of antipyrine in five grain doses every third hour with a stimulant to prevent the depressing effects of the drug, was of advantage. Certainly the temperature range was not so great after the use of this drug as before, but as we have seen from the chart of the first case, the temperature is very variable, so that it is difficult to judge as to the effect of drugs. The patient also received three drops of tincture of belladonna three times a day, for the control of the exhausting sweats. The diet was of the most nutritious and stimulating character, but as happens in most of these cases, all treatment was without avail.

Malignant endocarditis is a disease that was not recognized until within recent years. It is a rare disease. This is shown by the fact that Dr. William Osler, in a thorough search of the literature, was able to find only 209 cases. Since his admirable lectures were delivered in London two years ago, a great impetus has been given to the study of malignant endocarditis, and many cases are now recognized which before was entirely overlooked. The lines of investigation which have been pursued and which are still being pursued are in the direction of the explanation of the septic process, and the relation of malignant endocarditis to pneumonia, rheumatism and other infectious diseases.

MEDICAL EXPERT TESTIMONY, AS GIVEN IN THE COURTS AT PRESENT.[1]

BY A. F. HOLT, M.D.,
Medical Examiner, Middlesex County, Mass.

Some time after I had the honor to receive the appointment of orator, or reader for this occasion, I called on the secretary of the Society for the purpose of informing myself as to the nature of the papers presented by my predecessor at these annual meetings.

The principal object of this inquiry was to determine, if possible, why the reader, at these annual gatherings, is styled the orator. While this investigation did not quite satisfy the object of the research, it did inform the writer that some of the papers, from the subject, the eloquent and masterly manner of treatment of the subject matter, were well worthy the name of oration or essay; still a very large majority of them were descriptions of practical experiences, bringing together the results of careful observation and painstaking research, some on one subject and some on another, but all presented to the Society in a clear and forcible way, bringing to the members such profit as can only come from the relating of actual experiences, practical lessons to assist us, one and all, in our every day work.

[1] Address delivered before the Middlesex South District Medical Society, April 21, 1886.

I am sure the Society, made up, as it is, almost wholly of busy, hard-working practitioners of medicine, who have snatched an hour or two from their daily rounds of work to assemble here, much prefer to hear from me the result of some practical personal observation, rather than such a discussion as must of necessity very largely make up the oration or essay, even were I able to present the latter in an acceptable manner; for this reason, I have chosen for my subject one in some phases of which another more able than myself might be eloquent in oratory, or profound in essay, but which I purpose to treat in a plain, practical way, giving personal experiences and personal observation that have come to me in the last dozen years. That subject is medical expert testimony, as given in the courts at present.

The principal reason for selecting this subject for discussion is the standing, or rather, want of standing of the medical expert witness, not only before both the court and the bar, but also in the eyes of the community; the position of such a witness, as he stands to-day, can be described in a few words. With no influence toward bringing about the high purpose for which he has been summoned — that of an instructor of the court — without the respect of either the judge, the bar, or the jury, he is a discredit to himself and the, great profession to which he belongs.

During quite an experience in court, with a single exception, I have never heard medical testimony commended by the presiding justice, and that exception, I am happy to say, Mr. President, was in relation to evidence given by one of the oldest and most eminent members of this Society. Often I have heard the judge, in his charge to the jury, refer to such testimony in a way anything but complimentary to the medical witness, and quite as often it is ignored altogether.

Dr. Phelps, in an annual address delivered before a medical society in Ohio, quotes the following: "Professor Chaille, speaking for the medical profession, declares that with the power of medical science crippled at coroner's inquests, then prostituted by the partisan opinions of incompetent experts, then presented by interested advocates, and at last, when emasculated of all vigor, submitted for decision to those unable to estimate its weight, what wonder that such gross misapplication of medical knowledge brings upon it that public contempt which belongs to methods so monstrous, and to which true medical knowledge is a helpless, pitiable, disgusted victim?"

Lord Campbell says "that skilled witnesses come with such a bias on their minds to support the cause in which they are embarked, that hardly any weight should be given to their evidence." Chief Justice Chapman, of this State, observes: "I think the opinions of experts are not so highly regarded as they formerly were, for while they often afford great aid in determining facts, it often happens that experts can be found to testify to anything, however absurd." Judge Davis, of Maine, goes even farther, and says: "If there is any kind of testimony that is not only of no value, but even worse than that, it is, in my opinion, that of medical experts."

Judge Redfield, of Vermont, also says: "There is but one opinion as to the fact that this kind of testimony is extremely unsatisfactory."

Only a few months ago, I heard one of the most learned and respected members of the bar state to the

court, "Medical men are employed in these cases (suits for damages for personal injuries) just as lawyers are employed, to work up their side of the case, so far as the medical facts are concerned," and he went on to argue that it was perfectly right and proper that they should be so employed. This statement, of course, cannot be denied, but the argument is in no way in keeping with the purpose for which the expert is summoned.

As I have said before, my reason for selecting this topic for discussion is this discreditable standing of the medical expert as he appears before the courts to-day —a standing, as may be seen from the above quotations, recognized on all sides as a disgrace to our profession, a blot on the fair name of truth and justice, and a by-word and reproach in the eyes of the world. Who are the men, and what are the causes that have brought about this discredit upon the medical expert witness? Are they the quacks, the charlatans, the pretenders in medicine? From my own observation, I must answer emphatically, no; these irregular practitioners rarely appear on the witness stand. For nearly a dozen years I have been particularly interested in this matter, and during that time have taken every opportunity to hear and read medical testimony. This experience has taught me that the medical men who appear in our courts as witnesses are members of the regular profession. Some of the causes which have led to this condition of things I shall discuss farther on.

What is the nature and object of expert testimony, and who are the experts? Bouvier, in his law dictionary, gives, as a definition of the word expert, the following: "Persons selected by the court or parties in a cause on account of their knowledge or skill to examine, estimate, and ascertain things, and make a report of their opinions; witnesses who are admitted to testify from a peculiar knowledge of some art or science, a knowledge of which is requisite or of value in settling the point at issue."

Greenleaf, on evidence, says: "On questions of science, skill, or trade, or others of the like kind, persons of skill, sometimes called experts, may not only testify to facts, but are permitted to give their opinions in evidence. Thus the opinions of medical men are constantly admitted as to the cause of disease or of death, or the consequences of wounds; and as to the sane or insane state of a person's mind, as collected from a number of circumstances, and as to other subjects of professional skill; and such opinions are admissible in evidence, though the witness founds them not on his own personal observation, but on the case itself, as proved by other witnesses on the trial." Smith, in his leading cases, says: "It appears to be admitted that the opinion of witnesses possessing peculiar skill is admissible whenever the subject matter of inquiry is such that inexperienced persons are unlikely to prove capable of forming a correct judgment upon it without such assistance; in other words, when it so far partakes of the nature of a science as to require a course of previous habit or study in order to an attainment or knowledge of it."

Elwell, in referring to this matter, says: "Extra knowledge on questions of science, skill, trade, business, or other matters requiring special knowledge, qualifies the person thus informed to give opinions in courts of justice; this is contrary to the general rule that the witness must confine himself to facts, and leave the conclusion of those facts to be determined by court or jury under oath. An opinion is the judgment which the mind forms on any proposition, statement, theory, or event, the truth or falsehood of which is supported by a degree of evidence that renders it probable, but does not constitute absolute knowledge, truth, or certainty. These opinions, or conclusions of judgment, which make up such opinions of experts are the same in substance as the verdict of a jury or judgment of a court, which is nothing more than the opinion of such jury or court as to what is established by the facts in the case. This conclusion or opinion, in the latter case, is given under the sanction of an oath; so is that of the expert."

The professional witness to a certain extent assumes the duties of the jury in that he makes up opinions for them.

Reese speaking of legal medicine, says: "It should require no argument to show the importance of the knowledge of this science to the student and practitioner of both the professions of medicine and law. The former cannot entirely evade its claims, although he may seek to do so, since the very nature of his profession together with his assumed public position as an accredited physician renders him liable at any moment to be confronted with a case involving the intricate questions of homicidal, suicidal, or accidental death, of infanticide, of criminal abortion, of rape, of drowning, and of numerous other similar cases, all of which when they become the subjects of legal investigation must necessarily depend for their proper elucidation chiefly, if not solely, upon the physician who has previously given his professional attendance in the case, and who must subsequently give his evidence before the court and jury. How important then that the practitioner of medicine, even though he may have no special leaning toward legal medicine, should become acquainted, at least with the general principle and leading facts of this science."

What higher and more honorable position could a member of the medical profession occupy than the one indicated by the above extracts from the writings of the most able authors on this subject; provided the medical witness had the high standing he should have in the courts, a position that makes him, not only an instructor to the court and jury, but one that often compels him to assume the function of the latter, a position that in some respects is higher than that of the judge himself, for he in his judicial capacity, can give to the jury only the principles of law by which they are to be guided in making up their decision, and he can in no way give his own opinion as to what that decision should be.

How much depends upon what the medical expert may do and say on the witness stand! A single answer, and that answer purely a matter of opinion, may determine the disposition of thousands of dollars, yes, or upon a single answer may depend the life of a human being. An eminent writer has said, "No class of witnesses disposes by their testimony, of larger amounts of money than this class, the greatest fortunes ever collected together by financial ability have been distributed by medical men upon the witness stand in contests over the validity of wills. The law books are full of illustrations of this fact." Dr. Rush, in closing a lecture, delivered at the University of Pennsylvania in 1810, says: "To animate you to apply yourselves to the study of all the subjects enumerated in the introduction to our lecture, I beg you to recollect the extent

of the services you will thereby be enabled to render to individuals and the public, fraud and violence may be detected and punished, unmerited infamy and death may be prevented, the widow and the orphan may be saved from ruin, virgin purity and innocence may be vindicated, conjugal harmony and happiness may be restored, unjust and oppressive demands upon the service of your fellow citizens may be obviated, and the sources of public misery in epidemic diseases may be removed by your testimony in courts of justice."

Elwell, in his work on "Malpractice and Medical Evidence," in relation to the history of medical evidence, says: "Although medicine itself is as old as history, the learning of that science in its application to jurisprudence is of but very recent date. Not until the time of the Emperor Charles the Fifth of Germany, was there ever a recognition publicly of the value of medical evidence. In the Caroline Code framed at Ratisbon in 1832, it was ordained that the opinion of medical men should be received in cases of death by violence or unnatural means, where there was the least suspicion of criminal agencies having been used.

"The publication of this code encouraged the members of the medical profession to more fully qualify themselves for the new duties thus recognized and imposed. The result was that many books appeared very soon upon the subject of medical jurisprudence, and the importance of medical evidence.

"At first, the surgeon was only permitted to give testimony in courts of justice. Thus, in 1606, Henry the Fourth, authorized his first physician to appoint two surgeons in every city and town, whose duty it should be to examine all wounded or murdered persons and report the facts in the case, and as late as 1667 no such report was valid unless at least one surgeon sanctioned it." In 1692, it was admitted that physicians also knew something about medical matters that might be auxilliary to jurisprudence, and by law they were permitted to give testimony in the same case with surgeons. During the eighteenth century a large number of able writers devoted their lives to medico-legal investigation in Italy, France, and Germany. The Germans have especially excelled in this department, and furnished extensive and important contributions to its stores of learning, from Henke to the great Caspar. The proverbial, patient German research is not, perhaps, better illustrated in their theology and metaphysics, than in their investigations in, and contributions to, medical jurisprudence. A list of distinguished names also adorn the history of the science in France, headed by the celebrated Ambrose Paré and culminating in the distinguished Orfila. England has not been noted for her writers on medical jurisprudence until quite recently, but during the last few decades the very able works of Doctors Guy, Taylor, Christison, Woodman and Tidy have abundantly atoned for past short-comings in this direction.

The celebrated Dr. Rush of Revolutionary fame, was among the first in this country to call attention to this important subject, which he did in an introductory lecture already referred to.

In 1823, the first edition of Beck's Medical Jurisprudence appeared. Since that time many other enlarged and extended editions have been published, until now it is complete and exhaustive, standing in the very front ranks of medico-legal works everywhere. Also within the last fifty years a large number of other learned and able writers have published works on this subject, some treating of legal medicine generally, and others treating of special departments of it, until to-day America stands as well as most European countries, so far as the literature of this subject is concerned.

Notwithstanding we have so many comprehensive medico-legal works, the authors on this subject have nearly all confined themselves to the discussion of matters relating to criminal practice, and except in cases of will or other disposition of property where the question of sanity is the issue, I find but little has been written in relation to the giving of medical testimony in civil suits, and almost nothing in that particular class of cases where claims are made for money damages for personal injuries. When, and where, the custom of calling medical men to give expert testimony in such cases originated, I am not able to say. During my early professional experience, twenty-five years ago, I occasionally heard of medical men being called as expert witnesses in civil cases, but this was of rare occurrence, possibly, however, for the reason that such cases were then very rare. Since then, owing without doubt, largely to the very great increase in railroads and other corporations, suits for damages for personal injury have steadily increased, until to-day the courts are crowded with them, and as such claimants rely, of necessity, very largely upon medical evidence to support their cause, scarcely a day passes during the sittings of the courts, without one or more medical experts appearing on the witness stand. So far as the good name and honor of the profession are concerned, these civil suits, in which so much depends upon the medical testimony, are all-important, and in my opinion the medical evidence that has been given in such cases has had more to do toward bringing the medical expert witness into the humiliating position he occupies to-day, than any other cause.

What are the causes that have brought our profession to such a pass as experts, a profession in all other respects whose integrity and honor are above question or suspicion, even by the courts themselves?

To give all the causes that have helped to bring about this result, would take us far beyond the limit of this paper, and therefore I can only mention some of those that seem to me to be the most important. One of these is the training the medical man gets in his everyday life-work. This work, unlike that of any of the other learned professions, is done in the privacy of his office, or that of the sick chamber, away from the world's scrutiny, away from the world's criticisms, and the physician is accountable only to his own conscience, as to what he may do; he forms his own opinions and sustains them in his own way, having as an audience only his willing patient who accepts without question his conclusions as wisdom and truth.

In that close communion with himself, which is a necessity of his professional life, he draws further and further away from the outside world, creates and develops ways of his own of discussing such questions as are presented to him in his daily work, thus forming habits of reasoning purely the result of the bent of his own mind.

Such a training is little calculated to sustain or help him in the most difficult and trying position in which

he can be placed, that of the witness box, where, if he would do credit to himself and honor to his profession he must not only state his opinions clearly and distinctly, but must also, as clearly maintain them. That, too, he must do under the immediate eye of the judge, standing face to face with the jury and the bar, one member of which at least, is watching every word, every expression, every answer and every opinion that he may give to find some weak place in his testimony, some vulnerable point where he can make a successful attack; and often, I am sorry to say, this interested advocate is assisted in his assault upon the medical witness, by a brother doctor who sits at his elbow. I say such a training as the physician or surgeon gets from the experiences and necessities of his professional duties are little calculated to sustain him in the contests that await him on the witness stand. Another one of the principal reasons why doctors make such bad witnesses, as the lawyers say, is I believe the neglect to study the case as well as everything relating to or having a bearing on the medical questions involved thoroughly and carefully. I am sure it is quite common for medical experts to testify in cases where thousands of dollars depend on the medical facts and their proper interpretation, without ever giving the matter any real thought or study, or without even looking up the literature of the subject involved. Time and time again have I heard medical witnesses asked what books they have read on the subject, when they could not give the name of more than a single author, and often, not that. Some years ago I heard a doctor, who was on the witness stand as an expert in a case where damages were claimed for an injury producing the so-called pendulous bowels, asked, "What keeps the bowels in place?" After some hesitation, he answered, "The walls of the abdomen." Yes, "but what else keeps them in place, so that they do not get displaced or tied up"? After great hesitation, and embarrassment, he answered, "I don't know." This man was not an ignoramus but an educated physician, a member of the Massachusetts Medical Society, but who had come into court without the remotest idea as to the real purpose for which he was there; he had come there thinking perhaps he could tell the story to the jury, just as he had told it to his patients, without being asked the why and the wherefore of his opinions other than as his patient had asked them, and that they could be answered in the same way. Had such a witness been about to perform an important surgical operation, either alone, or in the presence of one or two physicians perhaps, where he was not quite sure of his anatomy or of his diagnosis, would he have brought his patient to the operating table until he had thoroughly looked up the anatomical points involved? Most certainly not, the most reckless surgeon would not trust himself to that extent. Still, he steps on to the witness stand, where he is to give opinions that are to be the foundation of justice between man and man, where he is to stand for the honor of his profession, under the trying ordeal of a sharp cross-examination before the world, with no especial preparation for such a contest; in fact, he goes there just as he would go to see one of his patients suffering from some trivial disease. I am sure that this case is not an exceptional one, and that careful painstaking study of the question about which the medical expert is to give evidence, is rather the exception than the rule. What wonder then that the medical witness sometimes leaves the stand he has taken a few moments before with so much assurance, defeated and humiliated.

(To be continued.)

ON RUPTURE OF THE TENDON OF THE LONG HEAD OF THE BICEPS BRACHII MUSCLE.[1]

BY GEORGE H. MONKS, M.D.

CASE I. P. O'D., laborer, aged fifty-two, came to me at the Out-Patient Department of the Carney Hospital about one hour after falling to the ground, while attempting to get off a street-car. He said that he struck upon his face and left shoulder. The shoulder was painful, and as if to keep it at as perfect rest as possible, he supported the left arm with the right.

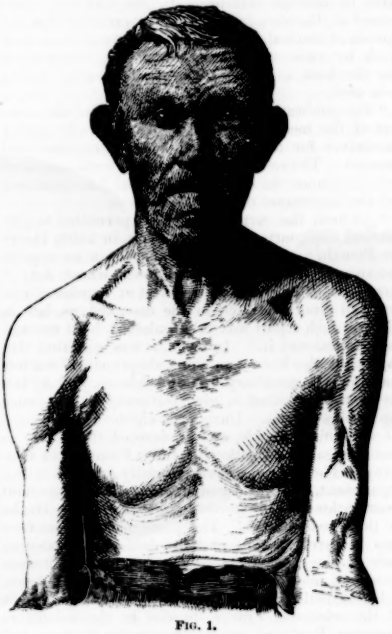

FIG. 1.

The belly of the biceps muscle was much more prominent than its fellow on the other arm, but did not impart to the touch that sense of resistance noticed in a well-contracted muscle; for it was, in fact, quite flabby. There was considerable tenderness along the bicipital groove, and active flexion of the forearm caused pain. The long tendon of the biceps could be distinctly seen, as well as felt, below the lower margin of the deltoid muscle. Figure 1 well represents the appearance of the deformity.

CASE II. T. L., a laborer, aged fifty-five, was sent to me by Dr. W. N. Bullard. The patient was shov-

[1] This is substantially the same paper as one read at a meeting of the Surgical Section of the Suffolk District Medical Society, on March 3, 1886. Since the reading, one new case has come to my notice, and is here recorded.

elling snow into a city cart, a few days before, and while doing so felt something snap in his right shoulder. Sudden and severe pain caused him to stop work at once. When seen the deformity was characteristic; and is well shown in Figure 2. There was a marked depression above the biceps on the outer side, and in this depression the tendon of the long head of the muscle could be distinctly felt.

Case III. For this case I am indebted to Dr. H. L. Burrell. J. W., aged seventy, while lifting up a cooking-stove on one side, felt something give way in his right shoulder, notwithstanding which, he kept on working for about half an hour. The pain was never at any time severe, and the only reason he sought medical assistance was because he knew "by the look of the arm that something was wrong." The deformity was exactly like that already described in connection with the first two cases.

Case IV. J. A., a German, fifty-three years of age, who had met with an accident a few weeks be-

Fig. 2.

fore, which had apparently caused both dislocation of the head of humerus and rupture of the tendon of the biceps, was referred to me by Dr. H. W. Cushing.

While the patient was at work a heavy chest fell upon him. He put up both hands to protect himself, and managed to throw off the chest to one side. In doing so, however, he felt a distinct snap in his right shoulder, accompanied by a stinging pain and inability to use the arm. The dislocation of the shoulder (subcoracoid) was reduced at the City Hospital, and it was not until this had been done that the rupture of the tendon was noticed.

The tendon of the long head of the biceps muscle has its origin at the upper part of the margin of the glenoid cavity. From this point it passes over the head of the humerus and between the greater and lesser tuberosity to the bicipital groove, down which it passes to end in muscle at about the middle of the tendon of the pectoralis major muscle. To hold this long tendon in its place, a special band of fibres continued down from the capsule of the shoulder-joint stretches across the groove. An offset from the synovial membrane of the shoulder-joint lines the upper two inches or so of the bicipital groove, and is then reflected back upon the tendon itself, as far as its point of origin at the margin of the glenoid cavity. The biceps tendon, therefore, covered by its own synovial membrane, is within the cavity of the shoulder-joint.

A rupture of this tendon appears in all cases to be due to an overstretching by a *violent contraction of its muscle*, or by *a sudden protrusion of the head of the humerus forwards*, or by *both causes* acting together.

A normal tendon whose strength is in proper proportion with the parts connected with it is very rarely ruptured. Cases are occasionally met with in the young and robust, where this accident has occurred.

A rupture occurring in those advanced in years, however, is a different matter. Here the tendon is presumably weakened by senile atrophy or shoulder-joint disease, so as to require only a slight force to completely tear it through. It is to ruptures occurring in such tendons that Volkmann has given the name of "spontaneous ruptures."

The four patients whose cases I have reported are elderly men, all over fifty years of age. Two of them declared that for several years previous to the accident they had had rheumatism in the same shoulder, where subsequently rupture took place. A third had partial anchylosis of one hip from chronic rheumatoid arthritis. Dr. C. B. Porter has told me that in a patient of his, who was advanced in years, he had found rupture of the long biceps tendon on both arms.

It is not an infrequent occurrence that one finds in the dissecting-room shoulder-joints of old persons, which have been the seat of chronic inflammation where the tendon of the biceps is worn away to a mere shred, and ready to break on the application of slight force.

Edmund Owen reports dissections of four such joints.[2]

Vogt,[3] in his treatise on surgical diseases of the upper extremities, gives an excellent wood-cut, taken from Rapp. Rupture of the tendon has occurred near its upper extremity. The lower end has fallen down the sheath while the upper one has a fibrillated extremity, suggestive of the wearing-away process which was taking place before the actual rupture occurred.

It seems to me that this weakening of the tendon, and consequent tendency to rupture must be more frequent than is usually supposed.

When we view the injury we are considering from a clinical point of view, we find that here again, we must distinguish between those ruptures resulting purely from violence and those in which the tendon has been previously weakened. There seems to be the same relative difference between the symptoms of these two different injuries as is observed between those of a fracture of the neck of the femur in the young adult and the same in the aged. When a rupture of the tendon occurs in a young and healthy individual, the injury is quite severe. A distinct snap is generally felt, followed by a stinging pain in the shoulder, and along the bicipital groove. The tenderness is marked. The patient holds on to the injured arm, and fears to move it. All motions are painful, particularly active flexion of the forearm upon the arm; *and when the*

[2] Med. Chir. Transactions, Vol. lviii, page 377.
[3] Die Chirurgischen Krankheiten der oberen Extremitäten, Stuttgart, 1881.

forearm is supinated, flexion is almost, if not quite impossible (Hueter).

The explanation of this appears to be that in flexion of the pronated forearm, the biceps has little to do, and that the flexion in such a case is accomplished principally by the action of other muscles, such as the brachialis anticus and the supinator longus, the biceps itself remaining comparatively at rest. In flexion of the supinated forearm, however, the biceps is obliged to do most of the work, and it is for this reason, therefore, that flexion of the forearm during supination causes so much pain and distress, and is often impossible. In addition to the above-named symptoms, an ecchymotic streak will sooner or later appear along the course of the bicipital groove.

What has been described as characteristic of the rupture of a strong, healthy tendon is also true of ruptures occurring in tendons previously weakened, except that the symptoms are here much less marked, and some of them may be even wanting entirely. Thus the snap of the breaking tendon is often not noticed by the patient, the pain and disability not marked, or may even be so slight as to enable the patient oftentimes to pursue his work without serious inconvenience, as is seen in Case III. The appearance of ecchymosis is rather the exception than the rule.

I have been able to apply Hueter's test in two of the cases reported here, soon after the injury. I placed a weight of two or three pounds in the hand of the affected side, and directed the patient to raise the weight to the shoulder by simply bending the elbow, with the forearm first in pronation and then in supination. Flexion in supination caused more pain, but the difference was not marked.

All cases of ruptured long tendon of the biceps, no matter what the cause be, show essentially the same deformity. The belly of the affected muscle is unnaturally full, so much so at times, as to suggest the idea of a tumor. Above the swelling is an abnormal depression, in which the tendon can be felt. The muscle, though apparently firmly contracted, is soft and flabby, and the patient is unable to make it as hard as the muscle of the other arm.

One should, in *all cases*, be able to feel the tendon running upwards from the collapsed muscle in the direction of the bicipital groove. I mean in all cases, except where that very rare injury, namely, rupture through the junction between the tendon and the muscle, has taken place. If we examine the outer head of the biceps muscle just as it issues from under cover of the deltoid, we find it is muscular, not tendinous. The tendon is entirely covered by the deltoid. If this tendon ruptures high up, the lower fragment slips down the groove, and can by felt below the margin of that muscle.

The diagnosis of a rupture of the tendon during life, when the deformity is marked, is a simple matter. Where, however, a partial rupture, or only a laceration of the sheath has occurred, the diagnosis is beset with difficulties, for the sign of most importance is entirely wanting, namely, the deformity. In such cases, reliance must be placed on localized pain and tenderness, and altered function of the muscle, following an injury which would, in favorable cases, be likely to cause a rupture. Gerster has reported a case in which he considers that a partial rupture occurred.[4]

The treatment of ruptured biceps is rest. A circular bandage around the arm, below the flaccid muscle, will raise it up slightly, and tend to relieve the ruptured tendon of all unnecessary weight. The elbow should be kept at the side, and the arm in a sling.

Pain and disability may exist for months, though this is rare, but eventually the function of the part is pretty sure to be restored. The torn end of the tendon acquires a new attachment, upon which the muscle learns to act. We lack proof that such an arm will ever again be as strong as before the accident, but we may be quite certain that it will eventually be a useful one. Such being the case, operative interference, such as laying open the joint and suturing together the two torn ends of the tendon, is contraindicated.

RECENT PROGRESS IN PATHOLOGY AND PATHOLOGICAL ANATOMY.

BY WILLIAM F. WHITNEY, M.D.

EXPERIMENTAL OBSERVATIONS ON THROMBOSIS.

EBERTH and Schimmelbusch [1] have continued their researches, a summary of which has been published in the JOURNAL.[2] Hitherto they had worked directly upon the small vessels of the mesentery and omentum, but now their attention was turned to the large ones of the body.

The thrombi, which were seen to be formed in the former, were composed essentially of blood plates among which were mixed red and white corpuscles, while fibrin was rarely found. This same composition was in the large vessels, after ligature, punctured or incised wounds. On the other hand, fibrin appeared in the clot between the three elements. This was found especially in the thrombi which had been produced after extensive cauterization, and where a wide destruction of the inner lining of the vessel had resulted, and also in those formed after the introduction of a foreign body (thread or bits of pith). During the first few minutes, in the later case, the plates alone adhered, while in from four to six minutes the fibrin was added. Even here they appear as the first cause, but in no case was there any reason to suppose that their alteration or destruction called forth the fibrin formation. Further, the mere fact of the presence of older clumps of plates, without the smallest trace of fibrin in the same clot is a refutation of this. Therefore it must be assumed that the running together of the plates and the clotting of the blood, are two entirely distinct processes, which are not only wholly independent of each other, but are essentially different. The blood plates are one of the normal constituents of the blood, and their thrombosis is simply a sticking together, a *conglutination*. While *coagulation* depends upon fibrin, which is a solid body formed from the plasma of the blood, (a crystallization).

When the fibrin takes part in building a thrombus, it does it in a very characteristic way. The appearance of the simple thrombus of plates is modified by it in a peculiar manner. The strings and threads unite the larger and smaller plates, and mingle with the small balls; they hold the red and colorless corpuscles fast, and produce in this way a series of new pictures. But in itself the quantity of fibrin is very small compared with the amount in an extravasated

[1] Virchow's Archiv., Vol. 105, p. 456.
[2] Boston Medical and Surgical Journal, Vol. 113, p. 508.

coagulum, or with the compact mass of the so-called buffy coat.

Coagulation is a process which occurs in circulating blood only in restricted amount, while conglutination is extensive and frequent. This is practically the most important, from the simple wounding of the wall of the vessel, by which it can be produced. For the streaming by of the blood, carrying with it the corpuscular elements can give rise to the large accumulation of the blood plates, to be met with here. On the other hand, coagulation is the method by which the clot is formed in stagnating blood. If this was absolute, then the clot made out of an included quantity of blood would present only the appearances of coagulation and not of conglutination. The possibility of an extensive contact of blood plates and possibility of their running together would be excluded. But perfect rest is impossible, for even the sinking of the corpuscular elements can make weak currents by which the plates can be brought in contact and undergo the viscous metamorphosis and thus conglutination arise, but it will never reach any marked degree. For in a given quantity of blood the number of plates is small, and there is wanting the continual addition of new elements, which can only be derived from the circulating blood.

It has been recognized for a long time that thrombi which has been formed in the living body by persistent circulation appear white or pale red, while simple blood coagula are of a dark red. This corresponds in the main with what has been said above, the conglutinations being white. But this is not absolute, but is dependent in a great measure on the number of included corpuscles in both cases.

Their experiments were commenced with the idea, founded on the generally accepted theory, that injury of the walls of a vessel led to the formation of a clot within them. The most varied injuries were therefore inflicted upon veins and arteries to find out the law that governs this. It soon became evident that the expected thrombosis did not follow the lesion, and as the cases multipled they were forced to the conclusion "that injury of the vascular wall does not always lead to thrombosis."

In those cases where it was formed, examination showed that the destruction of the wall, or alteration or defect of the endothelium had no direct influence on the formation of the clot. This was best judged of when nitrate of siver had been used as an escarotic, for its coloration showed how far its action had extended. Here blackened endothelium, or uncovered muscularis, or even necrotic shreds laying free into the lumen of the vessel were found to be without clots, while it was from their wrinkles or jagged edges that the point of departure was taken.

From this they infer that it is not alone the lesion of the vessel which leads to the clot formation, but that other factors are necessary. If all the rough points and projections are immediately covered with a clot, while the smoother but not less injured places in the wall remain free, it certainly points to a mechanical factor, and this is to be sought in the relations of the circulation. Over the smooth surface the blood can flow unhindered, while it finds obstruction in the uneven places. They think, therefore, that a vascular lesion leads only to thrombosis when a disturbance of the circulation is provoked by this at the same time. This can happen in two ways. First, eddies can be formed by abnormality of the lumen, by diverticula or prominences. Secondly, the speed of the stream can be so reduced that the cohesion about the axis disappears. Just as of bodies of different weights which are shot off with equal velocities, the specifically heavier preserve their original direction longest, while the lightest sink first to the ground. So the white corpuscles leave the axial stream the quickest, the blood plates after a marked slowing of the stream, while the red corpuscles still continue to move, when the current is almost at a standstill. If by the little eddies or by a reduction of the energy of the stream the plates are diverted from the centre and driven against the wall, then it is only a question whether these plates come in contact with a normal endothelium, which protects them from viscous metamorphosis till they can be hurried back into the current, or whether this has been injured. In the latter case they cohere, and a thrombus is the result.

ON THE DEGENERATION OF MUSCLE ASSOCIATED WITH HYPERTROPHY, AND ALLIED FORMS OF DISORDER.[3]

In the first part of the treatise there is given the clinical history and pathology of a peculiar case. It was that of an adult, without the history of any hereditary influence, who suffered from extensive progressive muscular atrophy, even involving the diaphragm. It was preceded by a marked increase in the volume of certain muscles, especially of the legs. The strength of these, however, in distinction to pseudo-hypertrophy, was very great. Later they became atrophied, and at last, in some, evidence of degeneration were shown by their reaction. A bulbar paralysis was never evident at any time, nor were the muscles of the head and larynx implicated.

There were no sensitive disturbances, beyond an occasional shooting pain in the extremities. Spastic symptoms failed utterly.

The author ends the history with the following words: The picture presented above cannot be made to fit any of the existing classes. Doubtless there is a great similarity to pseudo-hypertrophy, in which an increase of the volume of some muscles with true hypertrophy of the fibres has been shown. But in this case the small muscles of the hand were affected from the beginning as well as the deltoid, while certain muscles gave the reaction of degeneration. Further, the age of the patient at the commencement of the disease was far beyond the age of childhood, when the false hypertrophy occurs. Just as little did it agree with the juvenile form described by Erb, for in that disease there is no such early implication of the palmar muscles and the reaction of degeneration. On the other hand, it did not agree with the typical picture of atrophy of the anterior cerebral lobes (Duchenne-Aran's disease) from the failure of the bulbar paralysis. He regards the case essentially as one of primary myopathia.

In the carefully made anatomical investigation there was not seen, either with the eye or with the microscope any change in the spinal cord. The peripheral nerves were perfectly normal. The muscles were found to be altered in a manner similar to that in pseudo-hypertrophy. In general there was found an accumulation of a great number of fat cells in the majority of the muscles, while in a few there was a

[3] F. Shultze, Wiesbaden, 1886. Ref. in Fortschritte dur Medicin, 1886, p. 592.

marked increase of connective tissue, as well as the remains of hypertrophic, or atrophied, usually striated, fibres. The increase of nuclei in the diseased fibres was more pronounced than has been recorded by any one for pseudo-hypertrophy. But there was also wanting that regular distribution of growing nuclei in the universally extremely atrophied muscles, such as is found in poliomyelitis and in degeneration of the peripheral parts of the motor nerves. He also signals the presence of peculiar giant cell-like formations, which have not been recorded in any of the above-mentioned diseases. These are regarded as the remnants of muscular fibres, and he had met with them once before in a muscle penetrated by fibrosarcoma. Besides this, there were present in the degenerated muscular fibres, extensive formation of vacuoles, which recalled the tube-like atrophy described by Martini. They differed essentially from that form mentioned by Letten, as the result of embolic change, for in his case the striations were oblitérated, while here they were preserved. Moreover in the longitudinal sections the vacuoles had not the form of sinuous prolongations such as have been generally depicted. Since in the initial stage of the disease many muscles were found to be increased in power, and that besides this, markedly degenerated fibres were found in apparently normal bundles, and such as failed to show an increase of connective tissue with the microscope. Therefore the author comes to the conclusion that the fibres are primarily changed, and are independent of the nervous system as well as from any possible influence of the fat and connective tissue, which develops later.

In the general part which follows is given a complete description of the anatomical conditions in the different forms of progressive muscular atrophy. They are separated into the following classes: (1) cases of pseudo-hypertrophy with the results of the autopsies; (2) conditions found in the hereditary or ordinary form of progressive muscular atrophy; (3) conditions in atrophy without pseudo-hypertrophy or heredity, and without marked nervous symptoms, but with previous true hypertrophy; (4) cases of muscular atrophy with very few symptoms on the part of the nervous system and slight degeneration in the central nervous system; (5) cases of marked disease of the anterior cornua of the spinal cord alone, accompanied by a slowly-developing muscular atrophy. His own cases he refers to the first division. He disregards the division of the atrophies according to the principle of localization, which he regards as something secondary.

In respect to the distinction between neurotic and non-neurotic atrophies he holds that the presence or absence of true hypertrophy of the muscle to be the deciding point. "The hypertrophy has been found in neurotic atrophy up to the present time, very rarely or only in the later stages of the disease. It can also be absent in pseudo-hypertrophy and allied disorders, if at the time of examination a general marasmus has ensued, but in all other cases can be detected upon microscopic examination." Also, the early occurrence of an increase of connective tissue and fat speak in favor of primary myopathia. The presence of the reaction of degeneration (in the latter stages of the disease); of fibrillary twitching (to a limited degree), and of slight pains do not speak unconditionally against this. The appearance of atrophy at an early age and heredity are on the side of primary disease of the muscles. Where the first localization is in the muscles of the face and in the lower extremity their primary affection is probable, when it is in the muscles of the hand improbable, but not absolutely excluded.

CONTRIBUTION TO THE ÆTIOLOGY OF THE FREE BODIES IN THE CAVUM VAGINALE OF THE TESTICLE.[4]

According to Luscka, free bodies are formed by degeneration of papillary growths upon the tunica vaginalis (at the anterior edge of the epidydemis) through incrustation of epithelial plugs, from blood clots or deposits of fibrin.

Virchow and Kocher regarded them as the consequence and manifestation of a kind of inflammation of the tunic, designated as periorchitis prolifera, and the former also considered them as arising from the hydatids of Morgagni. In three out of eight cases the author found peculiarities in the structure of the cavum vaginale, which seemed to be of ætiological importance. Here it was the case of their production in pre-existing pockets, resembling diverticula. If such have originated from malformation or inflammatory adhesions, the epithelial plugs, fibrin and coagula could easily be deposited there. By the rubbing of the testicle and the tunica parietalis they can undergo change of place, till they are reabsorbed, or reach a spot where there is no movement. This is the sac of the epidydemis. If abnormal recesses of this are present, they may even reach them.

When they have reached the sac or one of its diverticula, the factors are wanting for their reabsortion. Namely the disintegration from movement and their contact with new parts of the serosa. And in the course of time changes take place in them resulting in the production of cartilage-like masses, often calcified in the interior.

CONTRIBUTION TO THE PATHOLOGY OF ADDISON'S DISEASE.

Nothnagel[5] has found that the pigment in the rete Malphigi was imported from the colored cell of the corium, which stood in close relation to the bloodvessels. Demiéville[6] observed that in these pigment spots there was an increase of nuclei in the vascular walls. Both authors arrived at the conclusion, that, in all probability, the pigment came from the blood, and was not formed in the corium cells.

Riehl[7] goes a step further. In the neighborhood of the cellular infiltration of the adventitia were often seen a larger or smaller number of migrated red-blood corpuscles, proper hæmorrhagic foci. In regard to those, different parts of the skin were found to be differently related. The most markedly pigmented were not necessarily nearest to the extravasations. Diffuse hæmorrhage, extending to the boundary of the subcutaneous tissue, or into the fat or connective tissue were most often met with. The separate corpuscles appeared either normal or with the well-known retrograde aspect. There was never noticed any scaly or crumbling masses of blood pigment. On the other hand, there were more or less strongly tinged cutis cells in the hæmorrhagic foci, or in their neighborhood. The corpuscles themselves or any parts of them were never seen in such cells.

[4] Hochenegg. Med. Jahebuch. der k. k. Gesellschaft der Aerzte, 1885.
[5] Zeitschrift f. Kl. Med., 1885.
[6] Revue Med. de la Suisse Romande, 1884.
[7] Zeitschrift t. Kl. Med., 1886.

In several places the lumen of some arteries and veins was stopped by thrombi. Such vessels showed regularly a disease of their walls, and almost always hæmorrhages in the adventitia.

Thus the idea of the deriving of the coloring matter from the blood has obtained a further support. The author regards the changes in the bloodvessels as the primary cause, as the second the extravasation of the red blood coloring material, and as the third, the change of this into the pigment of the cutis and its transportation into the epidermis. From his investigations it appeared that these hæmorrhages and the taking up of their coloring matter was not continuous, but intermittent. For near spots which were equally deeply stained, there were seen only fresh hæmorrhages, while in others only old extravasations.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.

S. J. MIXTER, M.D., SECRETARY.

March 3d. Dr. G. W. Gay presiding.

Dr. John Homans showed a specimen of

FIBRO-MYOMA OF THE UTERUS.

Dr. Homans spoke as follows: This fibro-myoma was removed ten days ago from a single woman, aged forty-six years. The presence of a tumor in the lower abdominal region had been known for two years. The hæmorrhagic flow at the catamenial periods has been growing more and more profuse. In size the tumor had increased rapidly during the past three months, until at the time of its removal it had reached a point three and a half inches above the umbilicus, at which point the abdomen measured forty-two and a half inches in circumference. In the vagina little or no neck to the uterus was felt, and the os lay high, the sound extended five and a half inches, but this was not the true uterine depth, as will be seen on an examination of the tumor. The weight of the tumor at the time of its removal was sixteen pounds, but it was very succulent and filled with fluid lymph. The tumor was dragged out through the abdominal incision by means of a large corkscrew and was held up while this wire, which I show you, and which came off today, was passed round it, and was fastened on an écraseur and tightened. The patient has done very well except for considerable abdominal distension from wind. The intestine was punctured twice with a small aspirating needle, but the greatest relief has been obtained by passing the faradic current through the abdominal walls several times a day, and giving subcutaneous injections of 1-20 grains of strychnia occasionally. Dr. James J. Putnam kindly showed me how to use the electricity and lent me a battery. This is the only case of laparotomy I have had out of some three hundred where the meteorism has been so great as to suggest obstruction, and necessitate mechanical interference. I do not show this specimen to encourage the operation of hysterectomy except in very exceptional cases, such as rapidly growing tumors, or those causing great hæmorrhage or great pain.

I have had two successful cases of hysterectomy in the last month, and I was prompted to operate on them because of a death from hæmorrhage in a case of fibroid tumor, which I saw a few weeks ago with Dr. Goodell, of Lynn. The patient was a fat married woman, about thirty-five years old, and Dr. Goodell was called to her on account of flooding. He summoned me later, and I found a large hard heavy fibroid, weighing, I should guess, about twelve pounds, and occupying the uterus pretty symmetrically. At the time I saw the patient there was no hæmorrhage, but the case seemed a very difficult one to operate upon. I had never known personally of a case of death from uterine hæmorrhage due to the presence of a fibroid, although I had seen women very exsanguine and feeble, and dragging along an existence which could hardly be called life, moreover, Keith had told me that he had never known of one, and that the authenticated cases were very rare. So I said to the patient and to Dr. Goodell, "If she had another bad flowing spell, I will remove either the ovaries and tubes or the uterus or both." I had only seen the patient once and I could not, with my previous experience and teaching, suggest an immediate operation. In three days, or at any rate within a week, Dr. Goodell wrote me that she had died of flooding. We could not get an autopsy. Influenced by this experience I suggested immediate operation in my last two cases. I am happy to say they are both doing well.

Dr. George H. Monks read a paper on

RUPTURE OF THE BICEPS TENDON,[1]

and presented two patients in whom this accident had occurred.

In reply to questions, the reader stated that the locality of the pain and tenderness is an important factor in diagnosis, that the short head probably hypertrophies, and that in no case has there been so great disability resulting from this accident as to prevent the patient earning his living.

DR. F. N. OTIS'S BLADDER EVACUATOR.

Dr. E. O. Otis exhibited, through the courtesy of Messrs. G. Tiemann & Co., Dr. F. N. Otis's simplified evacuator for the removal of débris from the bladder, after lithotrity. It consisted of a strong annealed glass bulb two inches in diameter, the reservoir; into one side of which a metal tube, forty mm. in circumference, curving down to its lowest part, is inserted. This is connected to the evacuating catheter by an india-rubber tube. Attached to the floor of the reservoir, by a bayonet joint, is a short, strong, glass bottle, the receiver. On the side of the glass bulb, opposite the tube connecting with the evacuating catheter, is another metal tube curving upward to near the top of the bulb. This is connected by another india-rubber tube with a strong rubber bulb, constituting an independent air-chamber. Two stop-cocks at the extremity of the flexible tube permit the removal of the catheter without leakage either from the reservoir or the bladder. At the base of the rubber bulb is a stop-cock to which the discharge pipe of a Davidson's syringe can be attached, by means of which additional water can be introduced into the bladder without removing the instrument, or by means of which the instrument can in the first place be filled.

The instrument is filled, preparatory to using, either by the syringe as before mentioned, or by plunging the evacuating end into a vessel of water of a tem-

[1] See page 496 of the Journal.

perature of 98°, and compressing the rubber bulb firmly once or twice.

The fluid in the receiver is removed from the influence of the current in either direction. This was shown by the tranquillity of the liquid in the receiver when water was forced through the bulb and reservoirs by the syringe attached to the bulb, and also by placing a colored solution in a bottle representing the bladder, and filling the receiver with pure water, or better, a denser fluid like glycerine, when, on pressure of the bulb, the colored solution was driven into the reservoir without materially coloring the water in the receiver. This fact is also of advantage when the urine is opaque from blood, enabling one to see, through the clear fluid in the receiver, the fall of the débris. The instrument has been proved to be very effectual, "quietly, quickly, and certainly depositing the calculous débris into the receiver, from which there is no possibility of return into the bladder."

Dr. Otis desired to express his thanks to Dr. F. N. Otis for his kindness in exhibiting the instrument to him some weeks ago.

NEW ASEPTIC SPONGES.

DR. J. W. ELLIOT exhibited some new aseptic sponges which he had made of worsted covered with muslin. He said we have all seen septic trouble from the use of unclean sponges, and we all know the difficulties of making ordinary sponges aseptic. These difficulties amount to almost an impossibility. Billroth found bacteria in sponges which had been soaked five days and more in five per cent. solution of carbolic acid. It is said that Tait never allows any one but his wife to touch his sponges.

In doing laparotomy, Dr. Elliot had always taken the entire charge of his instruments and sponges, never allowing assistants to clean or prepare them for him. He found that the preparation and care of the sponges required so much time and attention that a substitute seemed desirable. Various attempts had been made to find a substitute. Bits of linen and wads of absorbent cotton, as used by Schade, were absorbent only when dry, and even then were not very efficient. There were also objections to using dry materials, in that they collect dust and shed lint; also it is convenient to be able to wet a sponge in an antiseptic solution. After many experiments Dr. Elliot found that worsted which absorbs very slowly when dry was sufficiently absorbent when once thoroughly wet and wrung out. This sponge is cheap and clean, and has the great advantage of retaining its elasticity and absorbent power after boiling, which ruins a sponge.

The new sponges are made as follows:

Part of a skein of coarse, white Germantown worsted is doubled twice on itself and fastened in the middle so that each end makes a springy coil. The ends are then doubled together and the whole thing is covered with white muslin (the starch being washed out) making an elastic ball.

A ball of worsted thus constructed has an absorbent power about two-thirds as great as a sponge of the same size. It can be boiled and soaked in antiseptics without injury. It costs much less than a sponge. It requires less labor to make it than to prepare a sponge for an operation. It is much more certain to be aseptic. Any dirt shows readily on its white surface. When tested by wiping a mirror it leaves less lint on the surface than a sponge. Dr. Elliot had used them for six months, and was much pleased with them; wounds healed well after being wiped with them. The only objection he had found was that in laparotomy the muslin did not slide easily over the peritoneal surface, and this was only important when the sponge was passed down among the intestines through a small opening in the abdomen; under such circumstances the intestines would cling to the sponge; to obviate this he had had a few covered with silk mull. Each of the sponges could be safely used for several operations, but they are so cheap that it is better to use new ones for every important operation. He thought that they might prove useful in large hospitals where the care of the sponges is necessarily unreliable. The fact that they were somewhat less absorbent than real sponges is of less importance than one might suppose; for since the rubber tube tourniquet and pressure forceps have come into use we have less bleeding than formerly.

DR. GEO. W. GAY spoke of a case of

IMPALEMENT OF THE THIGH,

showing a large piece of board that was removed from the wound, which passed nearly through the upper part of the thigh. The patient made a good recovery.

DR. GAY also mentioned two cases of

OUTWARD DISLOCATION OF THE PATELLA,

recently under his care. The deformity was very characteristic and reduction was easy.

THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, November 4, 1886.

THE ERNEST KRACKOWIZER PRIZE.

The President, DR. A. JACOBI, as Chairman of the committee appointed by the Council in reference to the Ernest Krackowizer Prize Fund, the accumulated interest of which is available every third year as an award for an essay, the standard and merit of which are to be determined by a committee composed of the Presidents of the New York Academy of Medicine, of the Bellevue Hospital Medical College, of the Medical Department of the University of the City of New York, and of the College of Physicians and Surgeons, (unless the Academy should otherwise direct) announced that the committee had selected as the first subject, "New Observations on Osteo-Myelitis," and that all competing essays should be handed in on or before the first day of January, 1889.

DR. WILLIAM GILMAN THOMPSON read a paper on

THE MOVEMENTS OF THE HEART AND INTESTINES ILLUSTRATED BY PHOTOGRAPHY.

He said that several years ago he had been much interested in reading the account of a series of photographs of the horse taken while the animal was in motion, and that this had suggested to him the practicability of securing similar views of the movements of the heart under various conditions. Carrying this idea out he had been enabled to take photographs of normal hearts in full systole and full diastole, and also as affected by various stimuli, such as heat and different drugs.

In his early experiments he employed an ordinary camera; but more recently he had devised a form of

apparatus which rendered the work much easier, as well as more accurate. The difficulty about the ordinary camera was, that only one view could be taken at a time, and then the plate had to be changed. By the aid of his improved apparatus, however, he was able to take no less than six successive views on the same plate in the space of one second, a feat in photography which had never before been done. The problem was to revolve the plate, which was circular, and stop it six times in the second, each time exposing one-sixth of the surface; and this he had succeeded in accomplishing by means of an arrangement of cog-wheels turned by a handle. Each image was clear and distinct, without any blurring. The animal whose heart was to be photographed was anæsthetized, and an incision having been made in the median line, the heart was exposed, and a collar of celluloid slipped behind it in order to secure a light background, which was a matter of no little importance. The light used was strong sunlight, and the animals experimented on were cats, kittens, rabbits, rats, frogs, and pigeons.

The results were very interesting, and the movements, changes of form, and pulsations of the heart were distinctly shown. The shape of the apex was found to be greatly affected by different drugs, and of the various stimuli employed, heat was found to produce the strongest systole. Of the chemicals tried, glonoin, either painted over the surface or used hypodermically, was also very active in producing a similar effect; while chloral caused marked diastolic distension.

In photographing the movements of the intestines the same methods were employed. He had been able to demonstrate positively that two peristaltic waves sometimes occurred, moving simultaneously in opposite directions; although the preponderance of motion was towards the anus.

In summing up his observations, Dr. Thompson alluded to the accuracy of the photographic method which he had devised, the rapidity and ease with which data for scientific conclusions could thus be accumulated, and the facility with which the action of various cardiac and intestinal stimuli could be illustrated before classes of students.

In regard to the movements and form of the heart, he said:

I. The long diameter may or may not shorten in systole; but it usually shortens from one-fifth to one-thirteenth.

II. The transverse diameter usually shortens at least one-fourth.

III. The apex does not in all cases cause the impulse-beat; and this very frequently is produced by the hardened anterior wall of the heart pressing against the thoracic wall. The form of the apex varies greatly under the influence of different drugs.

IV. The contractile form of the right ventricle may out-last that of the left, and pathologically the two ventricles may contract independently.

V. The lumens of the ventricular cavities are capable of being entirely occluded by the circular fibres acting independently of the longitudinal and transverse; thereby demonstrating the immense reserve contractile power in all the cardiac fibres.

Dr. W. Gill Wylie read a paper on

TWO OPERATIONS FOR INTESTINAL OBSTRUCTION.

He said that out of the sixty-seven laparotomies which he had performed since June, 1885, six were not gynæcological. In only two of these, however, was the diagnosis made before the operation. In order to make the list complete, he gave a *résumé* of all the six cases.

The first was one of complete intestinal obstruction. The patient was a female, fifty years of age, who had had three children and one miscarriage. The last pregnancy was twenty years ago, and the menopause occurred four years ago. She had a uterine fibroid, and after the passage of the sound on one occasion an attack of peritonitis was set up. Afterwards she had great trouble in getting her bowels moved. Previous to the 6th of October last she suffered from colicy pains and distension of the abdomen. On that day she had much more severe pain and suffered greatly from vomiting. In order to relieve the pain large quantities of morphia were required. Ox-gall enemata and other means entirely failed in causing an evacuation of the bowels. Dr. Wylie saw the patient in consultation with Drs. F. N. Otis and Ward, and it was agreed that if a movement could not be secured laparotomy should be resorted to. The pulse and temperature were nearly normal, and the matter vomited was not stercoraceous. The patient was found to be very listless, but this could not be attributed to the opiates which she had been taking, since the pupils were not contracted.

On the 10th of October he operated. A short incision was made in the median line, and a number of small peritoneal cysts were discovered. A large uterine fibroid was found, and on one side of it was a mass of intestines closely matted together. The incision was then extended, and a large part of the intestines turned out of the abdominal cavity, when the cause of the obstruction at once became apparent. A loop of the ilium was found to be firmly bound down by a strong band of adhesions, and the obstruction thus caused was so complete that the intestines in the vicinity had turned black, and the lumen of the canal was destroyed. This firm band was cut, and the lumen was at once destroyed. The fibroid involved not only the uterus, but both broad ligaments; but as the patient had passed the menopause, it had already begun to atrophy, and it was not disturbed. The wound was closed in the usual way, and ten hours after the operation she had a copious liquid stool. The temperature never rose above 101, and the patient did perfectly well. Now at the end of three weeks her bowels were more free than they had been for ten years past.

A point of interest in connection with this case was the normal temperature and pulse, notwithstanding the presence of such a grave local condition, and Dr. Wylie said that he was convinced that many cases of laparotomy were followed by intestinal obstruction, which was generally mistaken for peritonitis. Until very lately, it had been the universal practice to keep the bowels confined for five or six days after laparotomy, notwithstanding the presence of tympanites and vomiting. He would not go so far as the laparotomist who said that a brisk purge was the best treatment for peritonitis, but he felt sure that a turpentine or ox-gall enema was often of great service after abdominal section. He had adopted the plan of always opening the bowels after the first twenty-four hours, if there was any indication for it; and in all cases, he did this at the end of three days, at all events.

The second case was one of partial intestinal obstruction. The patient was a woman twenty-five years of age, who was admitted to Bellevue Hospital in June, 1885. She was sent in as a "tumor case." There was a swelling in the left side of the abdomen, and the bowels were obstinately constipated. The uterus was firmly bound down by adhesions, but no very accurate diagnosis could be made, on account of the distension of the abdomen. On the 28th of June, abdominal section was performed, when it was found that there were extensive peritoneal adhesions, with partial intestinal obstruction. The glands were found to be greatly enlarged, and this was attributed either to syphilis or malignant disease. In the other cases which he had had, the obstruction was due simply to the pressure from a tumor, or adhesions due to the same cause.

The third case was one of laparotomy for peritonitis. The patient was a negro, who was admitted to Bellevue Hospital August 24, 1885. Two weeks before he had an attack of severe pain, and noticed that his abdomen was enlarged. After his admission the temperature was 103°, and the abdominal wall in the vicinity of the crest of the ilium was found to be indurated over a space of several inches. He made the diagnosis of suppurative peritonitis, and proposed to perform laparotomy, but Drs. Janeway and L. A. Stimson, who saw the case in consultation, did not think the operation called for. Afterwards, however, the late Dr. T. A. McBride saw the patient, and agreed with Dr. Wylie that laparotomy should be performed. Accordingly, he did the operation. A cavity was found, which contained ten ounces of pus, and the intestines were matted together. The cavity was kept washed out for several days, and the patient made a good recovery.

The other three cases were admitted to the hospital as "tumor cases." In the first he made an exploratory incision, and found tubercular meningitis present. The patient was a married woman, thirty years of age, who had had five children and one miscarriage. There was a small tumor in the left inguinal region, and he operated April 12, 1886. Two quarts of yellowish and comparatively clear fluid were evacuated, and he then found a semi-solid mass. There were many grayish-white nodules, the tubercular deposit involving both the intestines and the mesentery. Drainage was kept up as long as there was any fluid left to come away, and the operation was followed by very marked relief in the patient's sufferings. A sinus was finally established in the site of the wound, and ulceration followed. She died about the middle of July.

The fourth case was also one of tubercular peritonitis. The patient was a female, fifty-four years of age, who had had five children, and an exploratory incision was made in the same way.

The sixth and last case was that of a patient twenty-five years of age, admitted to Bellevue Hospital October 22. The abdomen was distended with fluid, and there was some jaundice. On October 23, an incision was made in the median line, and a trocar inserted into the peritoneal cavity, when three gallons of fluid were withdrawn. The nodulated condition of the liver there found showed that there was cancer of that organ.

In Germany, Dr. Wylie said, permanent drainage had recently been resorted to in cases of tubercular peritonitis, and in the two cases related in which he had tried it, the relief afforded the patients had been very great. He then went on to remark that in a large number of cases of abdominal dropsy, exploratory laparotomy was far less dangerous than tapping; and he contended that laparotomists in this country could never succeed in obtaining as good results as European operators as long as the mischievous practice of tapping continued in vogue. Patients with ovarian tumors, on account of the temporary relief afforded them by tapping, were very apt to defer applying to competent operators for their removal until a stage of exhaustion had been reached which left but a meagre chance of recovery.

Recent Literature.

An Introduction to General Pathology. By JOHN BLAND SUTTON, F.R.C.S. Philadelphia: P. Blakiston, Son & Co. 1886.

This work is developed from three lectures given at the Royal College of Surgeons, London, and is intended "to deal with the enormous collection of facts gathered together under the term pathology, by the application of the fundamental principles of the doctrine of evolution."

In the introduction, he states the three laws of evolution, as laid down by Huxley, and shows how that structural aberrations follow them, but can be grouped under two heads: 1. Correlation (including hypertrophy and atrophy). 2. Coalescence. In the remainder of the book, in which the subjects of general pathology are dealt with, his illustrations are largely taken from cases which have occurred in the lower animals, he having had exceptional opportunities for conducting autopsies on them in connection with the Zoological Gardens. The inheritance of pathological processes and their relation to evolution is everywhere insisted upon.

Of the separate parts of the book, that describing the various forms of cystomata is very full, and their relation to rudimentary structures is carefully shown. Here the value of comparative anatomy is manifested. The embryonic theory of the growth of tumors finds a warm supporter in him, and the relations of the different germinal layers are clearly indicated, and their peculiar bearings are well illustrated. The book, of course, is hardly expected to replace the larger and more comprehensive treatises for the general student, but will fill a gap in the collection of the pathologist, and is heartily to be recommended to them and to zoologists. The latter will thus be introduced to questions which should interest them, by illustrations from animals, with which he is well acquainted. The illustrations are abundant and well executed, while the dress of the book leaves nothing to be desired.

Studies in Pathological Anatomy. By FRANCIS DELAFIELD, M.D. New York: William Wood & Co. 1886.

The second part of Volume II has come to hand, and comprises the subjects of chronic phthisis and lobar pneumonia. The publication is continued in the same manner as the previous volume. We cannot help repeating what has already been said, that the work is chiefly valuable for its illustrations, and these are on such a scale as to be diagramatic in character, without being large enough to serve as wall pictures for class purposes.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, NOVEMBER 25, 1886.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: $5.00 *per year, in advance, postage paid, for the United States and Canada;* $6.00 *per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES, UPHAM & COMPANY,
283 WASHINGTON STREET, BOSTON, MASS.

THE DISCOVERY OF THE CIRCULATION OF THE BLOOD, AND ITS CONSEQUENCES.

IT cannot be denied that the discovery of the circulation is the most important physiological discovery of modern times, and it is befitting that once a year the Royal College of Physicians of England should commemorate this event, and the name of Harvey, by an oration in which due appreciation shall be given of the services of this and other similar benefactors of the human race. Without an understanding of the circulation, the true physiology of none of the internal organs could be known, nor could correct ideas be had of inflammation, or morbid processes generally. The advantages of this discovery to surgery —transfusion of blood, ligature of arteries for aneurisms, the tying of arteries to stop deep hæmorrhages, etc.,— are too obvious to require insisting upon here.

The Harveian oration of the present year (October 18th) was delivered by Dr. F. W. Pavy, who, after referring in fitting terms to Harvey's great work and the progress of medicine by experimentation, showed the application of the principles on which Harvey wrought to the great medical problem of the present day.

It was impossible that the circulation of the blood could ever have been discovered without experimentation. The *prima facie* evidence justified the views which the ancients held, and which are represented in Galen's works. Post mortem appearances showed the veins full of blood, the arteries empty, and the right side of the heart engorged. The viscera were found turgid with venous blood, and most prominent of all was the liver, the central rendezvous of all the veins of the alimentary canal, apparently exercising the function of receiving the chyle absorbed by the venous portal radicles, and elaborating into nutrient blood the food elements. It seemed easy to trace to this organ the completion of the digestive process, and the irresistible inference was that the chyle from the alimentary canal, made into blood in the liver, went forth from that viscus by means of the veins to nourish all parts of the body. There was a flux and reflux of blood through the veins comparable to the ebb and flow of the tide.

The ancients saw no particular reason to suppose that the arteries were *bloodvessels* but rather *air* vessels; it was known that blood issued from them during life when cut, but this could be explained from some supposed mysterious connection with veins; losing their air, blood would flow in to fill the vacuum. Galen, however, taught that the arteries conveyed air *and* blood; the blood in the arteries came from the left ventricle, having leaked from the right side through pores in the septum. It is significant in this connection to note that while the ligature of arteries has been generally considered of modern invention, and ascribed to Albucasis and Jean de Vigo, we have proof that Celsus and Paul of Ægina both understood and practised the tying of arteries for hæmorrhage, Celsus lived A. D. 5, and Paul of Ægina in the 7th century. The latter gives a very clear and complete description of the ligature of arteries in the Treatise on Angiotomy.

With reference to the air-conveying function of these vessels, the ancients were early impressed with these fundamental physiological facts: 1. The necessity of air for the maintenance of life; 2. The importance of respiration whereby air is drawn into the animal system. Without air, and without breathing, death speedily ensued, hence *air and breath* came to be synonymous with life itself. What became of the air (spiritus, anima) drawn constantly into the lungs? Here a resort to hypothesis was necessary in order to answer this question. The complex composition of the air was not known, nor was the law of diffusion of gases. Yet air was known to be very penetrating, and the mechanism was apparent by which it permeated the lungs, there coming in contact with the blood sent thither to nourish these organs by the pulmonary artery. The blood in the lungs was, as it were, fanned and purified of fuliginous and excrementitious matters by the tidal respiratory air, as the relatively foul and impure air of expiration testified. Just how the air got to the heart, was not so clear. As to the ancients, not only the pulmonary artery, but the four pulmonary veins were, with reference to the heart, efferent vessels. However, somehow the "vital spirit" penetrated through aëriferous tubes to the left side of the heart whose special function it was, to send it forth by the arteries. Galen's doctrine seems to be more like the true modern doctrine, namely, that the air in the left ventricle and in the arteries was held in solution in the blood, but Galen had no true notion of the circulation as such, was ignorant of the return of the blood from the lungs to the left cavities of the heart, and knew nothing of the relations which exist between the extremities of the arterial and venous systems.

Galen's teaching led mankind about as far as observation unaided by experimentation could go, and for more than fourteen centuries was authoritative in the medical world. With the renaissance of the 16th cen-

tury came the era of scientific experimentation, which inevitably lead to more correct views as to the circulation of the blood. The way was well prepared for Harvey's final demonstration. Vesalius, the greatest anatomist of the 16th century, had corrected Galen's mistake as to foramina of communication between the right and left cavities of the heart; had given a complete description of the heart's muscle and its valves; had tied arteries and showed that the course of the blood in those vessels was away from the heart, and towards the periphery. Cesalpinus had likewise tied the large veins, and had shown that the course of the blood in the veins was the reverse of that in the arteries and towards the heart. Etienne, Eustachius, Fabricius, Fallopius, had studied the structure of the bloodvessels, recognized the systole and diastole of the heart, and described the valves of the veins. Michel Servetus had by an acute course of reasoning arrived at the true view of the pulmonary circulation, showing that the great mass of blood conveyed to the lungs by the pulmonary artery, and which, he believed was destined to a higher and more general use than simply to nourish the lungs, was returned to the left side of the heart by the pulmonary veins. Columbus, independently of Servetus, had wrought out the problem of the lesser circulation in almost the same terms, following the course of the blood from the right side of the heart to the lungs, and thence to the left auricle.

It may almost be said that, had Harvey done nothing but reason from facts already in possession of the world, he might easily have arrived at the knowledge of the circulation; but it was his part by a series of brilliant and painstaking experiments on living animals to demonstrate all that had been affirmed by his predecessors, to coördinate the facts of observation, and to give to the world a true picture of the circulation. Before Harvey, the ultimate distinction of the blood in the arteries was a profound mystery. Harvey showed that *somehow* the veins were the complement of the arteries, but how the blood "circulated" from the arteries to the veins he did not know; it was reserved for Malpighi to complete his discovery by demonstrating with his rude microscope the capillary system. Harvey's experiments demonstrated the motor mechanism of the circulation, the use of the valves both of the heart and the veins, the lesser or pulmonary circulation and the course of the circulation both in the arteries and in the veins.

THE SURGERY OF THE PANCREAS.

A DOZEN years ago, the surgeon who should seriously propose "treatment of some of the injuries and diseases of the pancreas by direct surgical measures" would have been met with a smile of incredulity as a reward for his ridiculous boldness. Ovarian cysts might be removed under favoring conditions, but this was about the limit of abdominal surgery at that time. Now, all this is changed. Nature no longer has its own way in the unrestrained nurture of neoplasms in the hollow and solid viscera; the surgeon interferes and removes the new growths with courage, if not always with success. The stomach, the intestines, the kidneys, the spleen, all submit themselves to his scalpel and carbolized ligatures and sutures, and are at once admitted to the surgical literature, embellished with new and descriptive "ectomies" and "otomies," to establish a kind of brevet distinction for them.

It might be thought that the pancreas, in deep retirement, unobtrusive, serene, would escape the attention of the surgical explorer, and would remain to the end where nature designed it to stay. But its hiding place has been invaded, and its modesty is no longer a protection and a defence. In the surgery of the future, the pancreas must literally come to the front, and take its chances with its neighbors.

We have an excellent illustration of the brilliant boldness of the antiseptic surgery of to-day in a recent monograph by Professor Senn, the indefatigably industrious surgeon of the Milwaukee Hospital; his former labors in the field of surgical pathology and practice are well known, and this contribution to the scanty literature relating to the diseases and injuries of the pancreas, and their surgical treatment is new proof of the writer's originality, and a suggestive example of the tendencies of modern surgery.

Dr. Senn approaches the human side of his subject in the orthodox, experimental fashion. He studied the pancreas under a great variety of conditions in dogs and cats, and watched the results of traumatism upon the organ. He made complete section of the gland, lacerated it, crushed it to comminution, extirpated it wholly and partially, obliterated its duct by elastic constriction, ligated it at its centre, made external and internal fistulæ, carefully observing and recording the phenomena and results associated with all this vivisecting. In a general way, his conclusions appeared to him to justify the assumption that the human pancreas has been neglected as an organ of surgical interest. "Until now, the efforts of surgeons have been limited to the treatment of a few cases of cysts of the pancreas"; . . . "the surgery of the future will undoubtedly deal with contusions and lacerations of the pancreas in connection with visceral injury of some of its adjacent organs"; will excise inflamed or gangrenous portions of the gland; will perform "duodenocholecystostomy" for permanent and incurable obstructive lesions of the bile-duct resulting from pancreatic sclerosis; will cure pancreatic abscess by excision, or anterior fistula, or lumbar drainage; will treat cysts of the organ by establishing an external fistula; will remove its splenic portion when invaded by malignant disease, but will not attempt similar measures for the duodenal end; will search for and remove pancreatic calculi; and will favor "diagnostitial laparotomy" whenever there is doubt in any of these conditions.

Concerning that important pancreatic accident, idiopathic hæmorrhage, either diffuse or cystic, the author

offers but little new information. He recognizes the medico-legal interest of a condition, which, "more frequently than is generally supposed," causes sudden death "in some as yet unaccountable way"; such hæmorrhages, in his opinion, are the result of various causes, and are the expression of different pathological conditions. In the matter of treatment, the author says that "operative interference should be limited to the class of cases described under the head of hæmorrhagic cysts of the pancreas," and should consist of a "resort to abdominal section as the only means of arresting fatal hæmorrhage, by direct ligation of the bleeding points, or by removing such localized portions of diseased tissue from which the hæmorrhage has taken place."

PASTEUR'S NEW COMMUNICATION ON RABIES.

Pasteur has made another communication to the Academy in which he sets forth the results of his preventive inoculations for rabies, and the modifications which he has recently introduced into his method.

On the 31st of October, of the present year, 2,490 persons had submitted to the preventive inoculations. Of these, 1,700 were French, and on the facts relative to these, Pasteur bases chiefly his conclusions respecting the efficacy of his method. Out of these 1,700, there were ten fatal cases, that is one per 170. This, Pasteur affirms, would be under any circumstances an extraordinarily low percentage of mortality for rabies, and may be contrasted with the relatively high death rate of the bitten, not vaccinated, estimating the value of preventive inoculations. Before Pasteur's preventive system had come in vogue, there was, he states, an average mortality in the hospitals of Paris of 12 per annum; since November, 1885, there have been but two deaths from hydrophobia in Paris hospitals, and these were persons that had not been inoculated.

Concerning the fatal cases which had been under the preventive treatment, Pasteur reasons in this way: The greater number that succumbed despite the inoculation, were children that were bitten in the face, and only the simple treatment was applied to these cases. Now experience has demonstrated that the grave wounds require a more rigorous treatment. This was illustrated by the case of the Russians that came from Smolensk. These were 19 in number, had been bitten by a mad wolf, and three of them died, the first during treatment, the second and third several days after treatment was completed. "Dr. Grancher and myself," says Pasteur, "were troubled. Were the other sixteen going to succumb to the dreadful malady? Was our method powerless against wolf rabies? Remembering then that all the dogs which I had vaccinated with success had received for their last protective inoculation, matter from a virulent spinal cord, extracted that very day, and that Meister, the first one vaccinated, had completed his treatment by being inoculated from a cord extracted the evening before, we subjected the sixteen surviving Russians to a second and third treatment, going from the least virulent cords to those of four, three and two days. It is to these repeated treatments that we are in all likelihood to ascribe the immunity from rabies of these sixteen Russians."

Taking a hint from this experience, Pasteur has of late modified his treatment in the case of grave bites (wolf bites, bites about the head and face, deep bites) and this is now his procedure: "The first day we inoculate with cords of the twelfth, tenth and eighth day at 11 o'clock, A. M., at 4 P. M., and at 9 P. M.; the second day we use the cords of the sixth, fourth and second day, at the same hours; the third day we inoculate with cords one day old. Then the treatment is repeated; the fourth day with cords of eight, six and four days; the fifth day with cords of the third and second day; the sixth day cords of one day are employed; the seventh day, cords of four days; the eighth day, cords of three days; the ninth day, cords of two days; the tenth day, cords of one day. Three treatments occupying a space of ten days are thus pursued, each treatment ending with the freshest and most virulent cords."

This modified and greatly intensified treatment has, Pasteur thinks, since the time of its adoption, August last, been attended with results as gratifying as could be desired; of ten children grievously bitten about the face and head, and who have been subjected to this new method, not one has as yet succumbed to rabies. It being rare that children bitten on the head or face escape having hydrophobia within from four to six weeks, Pasteur thinks that the present immunity of these ten children is a proof of their being permanently protected.

Pasteur concludes his communication by reporting to the Academy the results of seven new experiments on dogs:

"It may be objected to the ordinary practice of vaccinating human beings *after* being bitten, founded on the vaccination of dogs *before* being bitten, that the immunity of the animals had not been sufficiently demonstrated after their certain infection by the virus of rabies. To reply to this objection, it suffices to refer to the refractory state of dogs after trepanation and intra-cranial inoculation of the virus of ordinary rabies. Trepanation is the most certain mode of infection, and its effects are constant.

"My first experiments on this point date from August, 1885. The success was partial. During the last few months I have taken up again these experiments, and these are the conditions of success: The vaccination must begin almost immediately after the inoculation (as soon even as the next day), and must proceed rapidly, so that the entire series of protective cords must be applied within twenty-four hours, then the treatment must be gone over again — once or twice — in the same manner, the vaccination being repeated every two hours.

"The immunity conferred under such conditions is the best proof of the excellence of the method."

MEDICAL NOTES.

— Cholera is reported as having appeared at San Rosario, Buenos Ayres, South America. With the large and constant emigration which is taking place from Italy to Buenos Ayres, there have doubtless been many opportunities for the transportation of the disease.

— The fasting mania has broken out in Europe, two Italians having attracted considerable notoriety in Paris, by long fasts. One of them is said to have previously fasted thirty days in Italy. Prof. Germain Sée, who has examined him, considers him a victim of nervous derangement, as it appears that the man had twice been an inmate of an insane asylum.

— A coincidence showing a probable septic origin for pneumonia, is reported in the *Lancet*. On the 18th of October, a man and his wife were admitted into St. Thomas's Hospital, suffering from acute pneumonia of respectively three and four days' duration. Each was aged thirty-two years. The disease ran an acute course, being little influenced by treatment, and they died at the end of four days within a few hours of each other. At the post-mortem examinations which were made on the same day, acute inflammation of the right lung were found in each; this had attacked chiefly the base in the case of the man, and the apex in the woman. It would appear that they had left their house, and moved into lodgings only two or three days before the commencement of the disease, on account of the bad smells, making it probable that the disease was of septic origin.

— Students of physiognomic science assert that, in estimating human character, the ear affords a better criterion than any of the other features, for which expression serves as a mask. The unelaborate ear, presenting no well-defined elevations and depressions, is thought to indicate selfishness and want of delicacy of perception. The possessor of a thick, well-shaped, highly-tinted aural appendage, set well forward, is usually ungrateful, grasping, and lacking in depth of feeling. A thin ear indicates keen susceptibility, and an ear that projects from head alertness. A small, soft ear, with no decided lines, is symptomatic of an hysterical, emotional, and shallow nature. A long, narrow ear belongs, in most cases, to a person of delicate perceptions. A broad ear is more coarsely practical. An ear, the cartilage of which is soft, indicates weakness, mental and moral. The creative ear has numerous and clearly-defined convolutions, but the perfect ear, which is the most beautiful, lies close to the head, gracefully rounded with pretty curves, strong lines, and firm, delicately-tinted cartilage.

BOSTON.

— A letter was received by the President of the Boston Druggists' Association on Thursday evening, the 18th inst., from the Board of Police Commissioners, requesting a conference with the officers of the Druggists' Association, in regard to the recent decision of the Supreme Court relative to closing places of business on Sunday. Agreeably with this notice, officers of the Association called at the office of the Board of Police, and were advised that the recent decision of the Supreme Court on the Sunday law would render an apothecary keeping his store open on Sunday liable to prosecution. An apothecary might be in his store to put up prescriptions or sell medicine only, when called for, but must keep the store door locked, opening it only when customers call.

In accordance with the recommendation of the Druggists' Association, its members generally complied with this order on Sunday, the 21st. Notices of various character, from grave to gay, were posted in the windows, informing would-be customers as to where the line regarding sales would be drawn. Prescriptions for medicines, however, were not required in all instances to be couched in the Latin tongue, nor even to be always reduced to writing. For some such cases, the direction was simply *fiat haustum, aegro stante.*

NEW YORK.

— The wife of Dr. C. R. Agnew and Miss Grace Dodge, a daughter of the late William E. Dodge, have been appointed by Mayor Grace, Commissioners of the New York Board of Education.

— Dr. Thomas F. Cleary, who was lately made Post-mortem Examiner of the Eastern District of Brooklyn, died November 19, from blood-poisoning caused by a dissecting wound.

— On the evening of November 18th, the anniversary address before the New York Academy of Medicine was delivered by Dr. William H. Draper, his subject being "The Principles and Progress of Modern Therapeutics."

— The twelfth annual meeting of the New Jersey Sanitary Association was held in the State House, at Trenton, on November 19 and 20. The address of the President, Prof. James M. Green, of Long Branch, was on "The Physiological Side of Education."

— The indictment against the Charities Commissioners of Brooklyn for their alleged neglect to properly care for the insane at the city asylum at Flatbush has been withdrawn, as the district attorney reported that sufficient evidence could not be obtained for their prosecution. Dr. Shaw, the medical superintendent of Flatbush Asylum, has resigned, and his resignation has been accepted.

— Mr. E. Heron Allen, an Englishman who has had much fashionable success at home, and is now giving seances in New York on "Practical Cheirosophy," or the science of the hand, has in his possession a magnificent album, containing representations of the hands of a large number of prominent persons. Under that of the Rev. Henry Ward Beecher is the following autograph note: "My father used to practise palmistry, but under afflictive circumstances, which disgusted me early with this science applied."

— The New York Flower and Fruit Mission, which recently closed its work for the season, reports that between May 17 and October 21, 89,205 bouquets

were distributed to the sick in hospitals and tenement-houses. Over 1,700 jars of condensed milk, beef extract, and jelly, with large quantities of berries, oranges, grapes, fresh eggs, and other delicacies, were also taken to the sick poor in their homes. The actual expense of the total distribution was less than $30, all contributions of money having been used for the purchase of suitable nourishment for special cases of illness.

Miscellany.

AN ANODYNE FOR USE IN VESICAL IRRITATION.

Dr. W. P. Copeland, of Eufaula, Ala., writes as follows to the *Medical Record:* "In almost every community there are old men who suffer from enlarged prostates, accompanied with a chronic inflammation of the neck of the bladder, rendering them miserable sufferers and a care and anxiety to their friends and families. Having had the professional care of several of this class of cases, and dreading the tendency they so frequently acquire to the administration of opium for the relief of pain, I resorted to various washes for injecting the bladder, resulting in my adopting a solution of benzoate of soda, ten grains to one ounce of water, with twenty to thirty drops of the green tincture of gelseminum; this is warmed and injected by the patient through a soft rubber catheter, whenever the pain is severe, and the catheter withdrawn, leaving the medicine to be voided in twenty to thirty minutes; or, where he is not able to pass anything from the bladder, the catheter is reintroduced and the medicine allowed to escape. My experience with this treatment has been so satisfactory that I cannot refrain from giving it publicity to the profession."

LOSS OF WEIGHT IN EPILEPSY.

Dr. F. Hallager, assistant physician to the lunatic asylum at Viborg, has according to the *Lancet* (August 21, 1886), endeavored to find an explanation of the diminution of the weight of the body after an epileptic attack. Kowalewsky was the first to draw attention to this fact. He states "that all persons suffering from any form of epilepsy lose in weight after each attack." "This occurrence is not equally great in every case, but depends on the duration of the disease and the intensity of the attack. The loss of weight is greatest after the first attack of a series of epileptic fits." Dr. Hallager has drawn up a table indicating the weight of the body and the quantity of urine and fæces excreted by the patients each day during his researches. Solid or liquid nourishment was given to the patients in proportion to the frequency and violence of the attacks. By a chart accompanying the paper in the *Nordisk Med. Arkiv*, it appears that whenever the curve of weight is considerably depressed after an attack there is also a corresponding elevation in the urine curve, of which no explanation is afforded by an increase of diet. When a loss of several pounds takes place, it is owing to the secretion of an abnormal quantity of urine. Dr. Hallager has been unable to determine whether the production of urea is also increased by the attack, but he believes the increased formation of urea is not sufficiently great to be of importance in the loss of weight. The diminution of weight caused by an epileptic attack he considers to be due to an increased secretion of urine after the fit. M. Kowalewsky insisted that psychic epilepsy, as well as the *grand* and *petit mal*, is followed by a diminution of weight. This is contrary to Dr. Hallager's opinion, who believes that there is no diminution during this psychic state except when the patient refuses all nourishment, and that the quantity of urine secreted is much less than normal. This is no doubt due to a reaction after the preceding augmentation. The fact that psychic troubles of an epileptic origin (especially when of long duration) may, like other maladies, cause a loss of weight, is natural; but this loss, which arises from general emaciation, has nothing in common with the diminution of weight after an epileptic attack, which results from a diminution of the quantity of water in the body, due to preceding augmentation of urine.

CASES OF REUNION OF CUT-OFF FINGERS.

Apropos of the discussion lately provoked in our columns, and continued by a correspondent in the present issue regarding the possibility of reunion of severed digits, we note the following cases in the *Medical and Surgical Reporter*, the first two being quoted from the *Russkaia Meditzina*, in which Dr. S. D. Ivanoff, of Briansk, furnishes details of interesting cases occurring in healthy soldiers, one of whom had accidentally cut away, by a stroke of an ax, the second phalanx of of his right forefinger, while another had severed in the same way, the second phalanx of his left thumb. In the former, the part hewn off was still united to the hand by means of a bridge of skin about two centimetres in breadth, the ax having passed through the first interphalangeal articulation, and chipped off a part of the base of the second phalanx. In the other case, the chopped off part was brought away in a glove; the weapon cut transversely a little above the interphalangeal articulation. In both of the cases the cut was clean, without any crushing of the parts. The first man was seen two hours after the accident; the second, three hours. The wounds were washed with a corrosive sublimate or carbolic solution, and the severed parts were accurately fixed by sutures in their normal situation, after which an iodoform dressing was applied. In both, perfect union by the first intention ensued, with return of sensibility and (limited) mobility.

A still more remarkable case was described by M. Thomas, of Tours, to the Paris Society of Surgeons. One of his patients, going home late without his key, wished to climb an iron railing with sharp-pointed tops. When dropping down, he felt himself retained by his third finger, which gave way at last; and, going into his room, he found that his finger was completely stripped of its integuments. A medical man, called at once, found the finger caught on the railing by a ring. The finger appeared complete, but was without the bone. M. Thomas was called an hour after, and reintroduced the bone into the finger. He applied two sutures, and bandaged the hand. The extremity of the finger became gangrenous. How-

ever, the patient had from this attempt the benefit of preserving nearly a phalanx and a half of his finger. M. Thomas has not found any such case on record.

THE TREATMENT OF TYPHOID FEVER IN THE NEW YORK HOSPITALS.

THE New York correspondent of the *Atlanta Medical and Surgical Journal* gives an interesting *résumé* of his inquiry as to the methods of treatment for typhoid fever in vogue at the larger hospitals of that city. At the New York Hospital calomel is occasionally given early in the disease if constipation exists. This condition is afterwards relieved if necessary by enemata. Antipyrine is given in drachm doses by the rectum, and repeated every three hours if required. It is not administered with stimulants, and no cases of collapse have occurred from its use. Sponging and the bath are also resorted to. During the year the death-rate from this disease was twenty per cent. At St. Vincent's Hospital no cathartics are given in typhoid. To reduce temperature quinine is administered in doses of ten to twenty grains. Here they do not give antipyrine, or employ sponging, wet packing or baths. The mortality is forty per cent. At the Roosevelt Hospital calomel is occasionally given early in the constipated cases. Antipyrine is used and cold water applied to the surface by the different methods. Constipation during the course of the disease is relieved by an enema every third day. Ten per cent. of the cases died. At St. Francis Hospital calomel is frequently given during the early part of the fever. Antipyrine has been used in large doses, but fifteen grains is now considered enough at once. Cold sponging is also resorted to. The death-rate here was seventeen per cent. Cathartics are not given at the Presbyterian Hospital. Antipyrine is used either in fifteen grain doses every three hours, or thirty grain doses when the temperature rises above 103° F. The bath and Kibbee cot are occasionally employed. For constipation enemata are administered. The death-rate was twenty per cent. At the Mount Sinai Hospital cathartics are omitted in this fever. Antipyrine is largely used. Local application of cold water is rarely made. Here the death-rate during the year was eleven per cent. In the German Hospital from fifteen to twenty grains of calomel are always given if the patient be admitted before the end of the second week. After this a daily enema is administered if constipation is present. Antipyrine is always accompanied with stimulants, and in two patients taking half drachm doses temporary collapse occurred. Musk in seven grain doses is considered here a brilliant heart stimulant, and is used three or four times daily in severe cases. Camphor ether is also used for the same object. The mortality was twelve per cent. In all these hospitals milk is the principal food in typhoid fever, and stimulants enter largely into the treatment of nearly all cases.

Correspondence.

A SIMPLE AND READY METHOD OF INFLATING THE INTESTINE.

BOSTON, 161 Beacon Street, November 22d, 1886.

MR. EDITOR,— In April, 1886, a gentleman came from New Brunswick to consult me in regard to an abdominal tumor. As he had come from a great distance, I felt that he ought to have other opinions besides mine, and I suggested that he should come to the Massachusetts Hospital and I would ask my colleagues to examine him with me. The other visiting surgeons and Dr. E. G. Cutler and Prof. R. H. Fitz, were kind enough to examine the case. After the patient was etherized it was suggested that the relations of the colon to the tumor could be better made out, if the intestine was inflated. One gentleman suggested putting some carbonate of soda in the bowel and then injecting an acid; another, the employment of a pair of bellows. In the mean time, a long tube had been passed up the rectum and its end was hanging out of the anus. It suddenly occurred to me that I could blow this up as well or better than any bellows could, and I took the end of the tube in my mouth and with very little exertion blew up the colon so that its outline stood out clearly; with a little more exertion the whole abdomen became tympanitic and distended. I used, I should think, about a third of the air in my lungs and I was quite surprised at the ease with which the intestines were blown up. Of course the surgeon need not do the inflating; with a long enough tube the patient might blow himself up unless he was etherized.

Very truly yours,

JOHN HOMANS, M.D.

CARDED *vs.* ABSORBENT COTTON.

SALEM, Nov. 17, 1886.

MR. EDITOR,—During the last ten years, the writer has used cotton-batting as it comes from the card-room as a light, protective dressing over the eye after the extraction of cataract. Unlike absorbent cotton, it retains its elasticity and does not become sodden and hard when wet, thus acting like a poultice, as does the patented article, neither is it irritating, as wool may be. Because of these qualities it would seem to be well-adapted for vaginal tampons as well as for the ordinary surgical use.

It can be readily sterilized by subjecting it to a high temperature, but this may be deemed hardly necessary, considering that the cotton comes into contact only with machinery from the time the balls are picked until the cotton leaves the carding-machine.

As the cheapest is sometimes the best, it may be stated that cotton mills (at least it is true of the one in Salem) will furnish carded cotton, in rolls, for fifteen cents per pound, while absorbent cotton costs nearly four times as much.

Very respectfully,

D. COGGIN, M.D.

REUNION OF SEVERED DIGITS.

LYNN, Nov. 16, 1886.

MR. EDITOR, — Apropos of severed digits, I can report a measure of success and of failure. Mr. Woods, in his haste to prepare kindlings for the morning fire, brought the axe down upon his thumb, severing the end in a diagonal line extending from the base of the nail downward nearly to the joint. The fragment dropped among the chips and the man had run a distance of twenty feet when he bethought him of the valuable piece left behind, and, returning, he picked it up, wiped it, and replaced it. The piece was secured by strips of plaster over the end, and no sutures were taken, for fear that the threads would produce a little pus which might burrow between the united surfaces and prevent a first intention. The thumb is now nearly as good as before, the only sequel being a diminished sense of touch.

A young man called upon me last summer who had just had the tip of his forefinger torn off at the base of the nail by a projecting nut in a revolving lathe chuck. As he was particular about appearances, an attempt was made to save the piece as in the above case. The case progressed well until I lost sight of the patient, two weeks later, when the fragment still remained in place. It had not a thor-

oughly healthy color, and sensation had returned but slightly. Some time after I learned that the piece shrivelled and came off. This case differed from the first in presenting a rough and mangled surface for apposition in place of a clean cut.

My father, Dr. I. F. Galloupe, had a patient some years ago whose finger was severed at its base in a sole-cutting machine. After running the length of the shop, the man returned for the fragment, in all a distance of two hundred feet, and replaced it. A perfect union resulted, and the finger regained complete motion, but sensation remained impaired. Another case occurred soon after in which the fragment united, but later it shrivelled and became practically worthless.

I think an attempt should be made to save the digit whenever the wound is a clean cut, and but little time has been lost in replacing it. Respectfully,

CHARLES W. GALLOUPE, M.D.

A MEDICAL BLACK LIST.

52 W. Cedar St., BOSTON, Nov. 18 1886.

MR. EDITOR, — Would it not be wise for neighboring physicians in the city to co-operate by mutual interchange regularly of the names of patients who do not promptly pay their medical dues, as well as of the names of acknowledged dead beats however respectable, for these classes are on the increase, and only by some such co-operation can a stop be put to their hateful form of swindle, which is founded on the credit-system in a great degree.

If the profession would adopt and force a cash system in practice, no need for mutual protection, such as is above referred to would ever be felt. In a small way this has been talked of in my neighborhood lately, and favored; it is a matter needing open discussion and attention. Very truly yours,

JOHN DIXWELL, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 13, 1886.

Deaths reported 1,966: under five years of age 697: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 392, consumption 311, lung diseases 221, diphtheria and croup 161, diarrhœal diseases 67, typhoid fever 47, measles 52, cerebro-spinal meningitis 17, malarial fever 17, scarlet fever 11, erysipelas nine, whooping-cough eight, puerperal fever one. From measles, New York 42, Pittsburgh ten. From cerebro-spinal meningitis, New York ten, Philadelphia two, Baltimore, New Orleans, Pittsburgh, Nashville and Worcester one each. From malarial fevers, New York nine, New Orleans six, Philadelphia and Baltimore one each. From scarlet fever, New York and Philadelphia four each, Pittsburgh two, Boston one. From erysipelas, New York four, Philadelphia three, Boston and Pittsburgh one each. From whooping-cough, New York three, Philadelphia two, Baltimore, District of Columbia and Nashville one each. From small-pox, New York and Brooklyn one each. From puerperal fever, Pittsburgh one.

In the 19 cities and greater towns of Massachusetts, with a population of 965,628 (population of the State 1,941,465), the total death-rate for the week was 19.33 against 19.80 and 18.07 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,095,817, for the week ending October 30th the death-rate was 18.5. Deaths reported 3,220: infants under one year of age 891; acute diseases of the respiratory organs (London) 295, diarrhœa 130, scarlet fever 84, measles 72, fever 63, diphtheria 35, whooping-cough 17.

The death-rates ranged from 11.9 in Derby to 30.0 in Wolverhampton; Birmingham 15.4; Hull 19.1; Leeds 22.0; Leicester 17.9; Liverpool 22.4; London 17.4; Manchester 24.5; Nottingham 21.6; Portsmouth 15.3; Sheffield 16.1.

In Edinburgh 13.9; Glasgow 23.4; Dublin 21.9.

The meteorological record for the week ending November 13, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps: —

Week ending Saturday, Nov. 13, 1886.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 13, 1886, TO NOVEMBER 19, 1886.

GREENLEAF, C. R., major and surgeon. Relieved from duty at Columbus Barracks, Ohio, and ordered for duty as attending surgeon at headquarters, Division of the Missouri, and examiner of recruits at Chicago, Ill. S. O. 268, A. G. O., November 17, 1886.

TILTON, HENRY R., major and surgeon. Relieved from the duties of attending surgeon at the headquarters, Division of the Pacific and Department of California. S. O. 96, Division of the Pacific, November 9, 1886.

WATERS, W. E., major and surgeon. Ordered from Fort Spokane to Vancouvre Barracks, Wash. Ter., for duty at that post. S. O. 197, Department of Colorado, November 8, 1886.

Paragraph 8, S. O. 257, A. G. O., November 4, 1886, is so amended as to direct Major V. B. Hubbard, Surgeon, to report in person to the commanding officer Columbus Barracks, Ohio, for duty. Paragraph 3, S. O. 268, A. O., November 17, 1886.

SMART, CHARLES, major and surgeon. Granted leave of absence for one month. S. O. 265, A. G. O., November 13, 1886.

CALDWELL, D. G., major and surgeon. Granted leave of absence for one month, with permission to apply for twenty days' extension. S. O. 150, Department of Platte, November 12, 1886.

MACAULEY, C. N. B., first lieutenant and assistant surgeon. Granted leave of absence for twenty days. S. O. 118, Department of Dakota, November 8, 1886.

CROSBY, W. D., first lieutenant and assistant surgeon. Ordered from Fort McDowall, A. T., to Fort Bowie, A. T. S. O. 110, Department of Arizona, October 29, 1886.

MORRIS, E. R., first lieutenant and assistant surgeon. Ordered from Fort Bayard, N. M., to Fort Thomas, A. T. S. O. 110, Department of Arizona, October 29, 1886.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING NOVEMBER 20, 1886.

NASH, FRANCIS S., passed assistant surgeon. Ordered to special duty Smithsonian Institution, November 26, 1886.

RHOADES, A. C., medical inspector. Ordered to special duty attending officers and families, New York City.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE FOR THE WEEK ENDING NOVEMBER 13, 1886.

AMES, R. P. M., passed assistant surgeon. To proceed to Vineyard Haven, Mass., as inspector, November 10, 1886.

URQUHART, F. M., passed assistant surgeon. Granted leave of absence for seven days, November 8, 1886.

WASDIN, EUGENE, passed assistant surgeon. Granted leave of absence for seven days, November 11, 1886.

MAGRUDER, G. M., assistant surgeon. Relieved from duty at Norfolk, Va.; assigned to duty at Marine Hospital, Chicago, Ill., November 10, 1886.

DEATH.

Died in Pau, France, November 19, 1886, Luther Parks, M.D., M.M.S.S., aged sixty-three years.

SOCIETY NOTICES.

NORFOLK DISTRICT MEDICAL SOCIETY. — A meeting for Scientific Improvement will be held at the Hall of the Roxbury City Guard, 67 Warren Street, Roxbury, November 30, at 7.45, P.M. Communications: I. "Puerperal Eclampsia, with Cases," Isaac W. Starbird, M.D. The discussion will be opened by Sarah M. Crawford, M.D. II. "Notes on Abscess of the Liver, with Cases," Daniel D. Gilbert, M.D. The discussion will be opened by John A. Tanner, M.D. III. "A Case of Chronic Cirrhosis of the stomach, with Specimen," Wm. P. Bolles, M.D.

S. ALLEN POTTER, M.D., *Secretary.*

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION. — There will be a meeting of this Section on Wednesday evening, December 1st, at eight o'clock, at 19 Boylston Place. Dr. John Homans will show a patient upon whom he has successfully operated after the method of Mr. Adams for the relief of Dupuytren's contraction of the palmar fascia. Dr. E. H. Bradford will read a paper on "Amputation of the Hip-Joint in Hip Disease." Dr. Royal Whitman will report four cases of Excision of the Hip performed in 1882, and will exhibit one patient.

GEORGE H. MONKS, M.D., *Secretary.*

J. COLLINS WARREN, M.D., *Chairman.*

NOTE.

The Archives of Gynæcology, Obstetrics and Pædiatrics, New York, will be issued monthly, and commencing January, the parts will so appear, instead of bi-monthly as heretofore.

BOOKS AND PAMPHLETS RECEIVED.

Transactions of the New Hampshire Medical Society at the Ninety-Sixth Annual Session. Held at Concord, June 15 and 16, 1886.

First Annual Report of the State Board of Health and Vital Statistics of the Commonwealth of Pennsylvania. Harrisburg, 1886.

Smithsonian Miscellaneous Collection. No. 490. Additions and Corrections to the List of Foreign Correspondents, to January, 1885.

A Manual of Diseases of the Nervous System. By W. R. Gowers, M.D., etc. Vol. I. Diseases of the Spinal Cord and Nerves. Philadelphia: P. Blakiston, Son & Co. 1885.

Diseases of Tropical Climates. Lectures Delivered at the Army Medical School. By William Campbell Maclean, M.D., C. B., etc. London and New York: Macmillan & Co. 1886.

Transactions of the American Surgical Association. Volume Fourth. Edited by J. Ewing Mears, M.D., Recorder of the Association. Philadelphia: Printed for the Association, and for sale by P. Blakiston, Son & Co. 1886.

Smithsonian Contributions to Knowledge. No. 647. Researches upon the Venoms of Poisonous Serpents. By S. Weir Mitchell, M.D., and Edward T. Reichert, M.D. Washington: Published by the Smithsonian Institution. 1886.

Eighth Annual Report of the State Board of Health of Illinois, with an Appendix embracing (*a*) Report on Disinfection and Disinfectants; (*b*) Coast Defenses against Asiatic Cholera; (*c*) Report of Proceedings, Sanitary Council of the Mississippi Valley; (*d*) Meteorological Tables; (*e*) State Sanitary Survey and House to House Inspection; (*f*) Vital Statistics of Illinois and Coroner's Inquests; (*g*) Medical Education in the United States and Canada, 1765–1886.

Lecture.

ON DIET IN ALBUMINURIA.[1]

A LECTURE ON ALIMENTARY THERAPEUTICS.

BY PROFESSOR DUJARDIN-BEAUMETZ,
Physician to Cochin Hospital, etc., Paris, France.

GENTLEMEN: In the foregoing lecture, we studied the alimentary regimen of diabetes; I shall devote the present lecture to the subject of diet in albuminuria. Nothing is more natural than to compare diabetes with albuminuria. Has it not been shown again and again, since the first experiment of the kind made by Claude Bernard, that, in injecting albumen into the blood, you determine its passage in the urine? Have not Hammond and Parkes pointed out that an exclusively albuminous diet provokes albuminuria? The carefully-conducted experiments of Semmola are equally to the point, in showing that it suffices to inject under the skin of dogs a certain quantity of albumen, to see the latter speedily make its appearance in the urine.

These last experiments present the greatest interest, and in a recent communication made to the Academy of Medicine, Semmola has indicated their high importance. In injecting under the skin of dogs, for five or six days in succession, fifteen or twenty grammes of white of egg daily, in four or five hypodermic injections, you determine in these animals an experimental Bright's disease, that is to say, albuminuria, the albuminous dyscrasia, with progressive diffusibility of the albuminoids of the blood, diminution of the ordinary amount of urea-production, dropsies, and lastly, renal lesions absolutely like those that are observed in Bright's disease.

Hence it is that many authorities, struck by the points of resemblance between diabetes and albuminuria, have not hesitated to regard the latter as the result of an augmentation of the albuminoid principles of the blood; in fact, of a hyper-albuminosis, comparable to hyper-glycæmia. Gubler, who has the most completely developed this theory, in order well to indicate the points of contact which exist between diabetes and albuminuria, has described the latter under the name of *leucomuric diabetes*, thus modifying the appellation of leucomatic diabetes, which Paulinier, in 1814, had given to this disease.

But when you investigate more deeply this physiological and clinical problem, you see how great is the difference between these two forms of diabetes, glycosuric and leucomuric diabetes. First, while we know with tolerable clearness the nature of glucose and its modifications, we are still profoundly ignorant as to the composition of the different albumens, and we are hardly able to distinguish the albumen of egg from that of blood (serum). This, however, is only one of the small aspects of the question; the capital point is that the quantity of albumen which one finds in the urine is only secondary, and it is the renal alteration which plays the most important part. One patient, for instance, may void quantities of albumen, eight to ten grammes a day, and his general health remain relatively good, while another, in whose urine you will find scarcely a trace of albumen, presents all the symptoms of a fatal uræmia.

Wherefore this difference? It is due altogether to the state of the renal filter. Without entering here into the discussions which have been carried on between the humorists and the solidists relative to the pathogeny of Bright's disease, it must be borne in mind that when we are called to treat a case of chronic albuminuria, it is at an advanced period of the affection, that is to say, when the lesions of the kidneys are more or less pronounced. The prognosis, then, depends not on the hyper-albuminosis, but on the more or less profound alterations of the kidneys, and the retention therefrom resulting, of extractive matters, and of those toxic products which Bouchard has made known to us under the name of *urotoxine*. Uræmia, the terminal period of albuminuria, depends, then, not on the quantity of albumen contained in the urine, but on the state of the renal filter.

We cannot, then, in treating albuminuria, take as our guide the mere decrease of albumen in the urine; hence our indications are necessarily somewhat vague, and based rather on empiricism than on sound physiological data. The hygienic treatment of albuminuria ought to fulfil several indications, which Semmola has summed up in the following terms:

(1) To furnish to the patient a diet which shall be readily assimilable, requiring the least possible labor for its preparation on the part of the digestive organs; (2) moderately to excite the cutaneous functions, and promote elimination thereby; (3) to facilitate the assimilation and combustion of albuminoids introduced by the food.

Before taking up the first of these indications, which will demand our principal attention, I must say a few words about the second and third. It is a matter of capital importance to promote the cutaneous functions, and Semmola, in a very interesting communication, has shown us that in true Bright's disease there are alterations of the skin characterized by an atrophy of the malpighian layer and of the sudoriferous glands, and since 1861,[2] he has pointed out the importance of the care of the skin in this disease. Hence he recommends methodical and repeated applications of dry frictions and massage, combined with hot-air baths, to favor sweating; he approves of the Scotch douche, but discards altogether the cold water treatment. He also disapproves of forced muscular exercises.

As for the third indication, which consists in favoring the combustions of albuminoid substances. Semmola recommends living in a mild, dry air, and particularly in a climate with a constant temperature; therefore, the professor of Naples advises patients living in variable climates not to quit their rooms, and to take abundance of muscular exercise in an apartment maintained at a constant temperature of from 19° to 20° C. He rightly insists on the extreme impressionability of the skin in Bright's disease, and compares it to a very sensitive hygrometer. To these means should be joined inhalations of oxygen, and baths of compressed air. I have often seen albumen disappear from the urine under the influence of this atmospheric treatment.

Let us now return to our first indication, and study the dietetics of albuminuria. As a guide in the alimentary treatment of Bright's disease, I shall follow chiefly the directions of Semmola, Senator, and Bouchardat, and I shall also avail myself of personal researches which I have made on this subject, many of which have been embodied in the thesis of my pupil,

[2] Semmola. Gazette des Hôpitaux, August 29, 1861.

Nollet.[3] The general notion which has directed the dietetic rules applicable to the albuminuric has been borrowed from the doctrine which has established the alimentary hygiene of the diabetic. Just as in accordance with what we saw in the last lecture on "Diet in Diabetes," it has become a custom to suppress from the diet of the glycosuric all alimentary substances containing starch or sugar, so, also, has it been proposed to prescribe for patients with Bright's disease a diet containing the least possible quantity of albumen, and abstinence from albumen has been regarded, in the latter case, as almost of as much importance as abstinence from sugar in the former.

But before taking up the details of this kind of dietetics, I must speak of a food whose favorable effects in Bright's disease are universally acknowledged. I refer to milk. Milk diet has been applied in the treatment of anasarca from the most remote antiquity, and we see the father of medicine recommending milk in the treatment of dropsies. This traditional practice was observed down to the beginning of this century, and even furnished Guy Pastin with his savage remark *à propos* of Mazarin, whom he detested: "We have him with us still; he is dropsical, lives on milk and will not die." But it must be remembered that it was Chrestien, of Montpelier, who, in 1831 again called the attention of the medical world to the utility of milk in the treatment of albuminuria and nephritis. Pecholier and Guignier, belonging to the same school, next showed all the advantages of the method counselled by Chrestien, while still later, Jaccoud, and his pupil Lemoine, have reported excellent results from a regimen of pure milk in all forms of nephritis. Therefore, we are justified in saying that to-day the application of milk diet to the treatment of albuminuria is accepted by all authorities, and everywhere now nephritic patients are subjected to this regimen as a matter of routine.[4]

As I have told you before, the mere fact of albumen in the urine is not of chief importance, but rather the degree in which the kidneys are affected, and you readily understand that the milk diet must be powerless to restore the malpighian bodies and tubules when they are clogged and destroyed by the renal sclerosis. In any event, it is always milk which should serve as the basis of your regimen. But as milk diet cannot be indefinitely continued, and as there are, moreover, patients to whom its usage is repugnant, it is necessary to have recourse to other kinds of food, and here it is that the rules laid down by Semmola and Senator, and which pertain both to the quantity and quality of aliments find their applicability.

As for the quantity, it has been observed that the proportion of albumen in the urine always augments after a too copious repast. You should then always insist that your albuminuric patient shall eat but little at a time, and that they shall have numerous light meals during the day. As for the quality of the food, those suffering from Bright's disease ought to make a judicious choice of alimentary substances and absolutely discard certain articles of diet, and first in the category of things prohibited we should place eggs. You know that an experimental albuminuria has been determined by an exclusive diet of whites of eggs. Stokvis has studied quite thoroughly the influence of white of egg in albuminuria, and he has shown, as previously Legart, Brown-Séquard, and Hammond had done, that two conditions are necessary in order that albumen ingested may pass out in the urine: first, that nothing but eggs shall be eaten; and second, that they shall not be cooked.[5] In fact, it takes but little cooking to prevent the filtration of albumen through the kidneys. I ought, however, to remind you of the curious experiment that Claude Bernard performed upon himself. This celebrated physiologist relates that having eaten several hard-boiled eggs after a short period of fasting, he was surprised to find his urine albuminous. Hence, while admitting as scientifically demonstrated, the facts as related by Stokvis, I nevertheless believe that it is better to be chary in the employment of eggs, even when cooked, in albuminuria.

As for meat, Senator is of opinion that it should be suppressed from the diet of the albuminuric, or at least, that usage should be made of only a little white meat; while, on the other hand, he recommends a vegetable diet under all its forms, as well as fats. I have made large use of vegetable diet in albuminuria, and must acknowledge that in a great number of cases I have derived much advantage therefrom. Amylaceous substances, vegetables, fruits, along with fats and milk, compose quite a sufficient dietary.

Among vegetables there is one which plays an important rôle in the treatment of albuminuria; I refer to the bulb of the *allium cepa* or the onion. Lerres, of Alais, in 1859[6] maintained that with the onion, which should be eaten raw, one might cure Bright's disease. But what detracts very much from the conclusions of Lerres, is that he ordered at the same time a milk diet, so that it is difficult to say how much credit was due to the onions for the good results obtained; and although Claudot and Pantiea have reported similar cases, there is reason to doubt the curative properties of the onion in this disease. At the same time, as this vegetable is relished by most patients, there is no reason why they should not be allowed to eat freely of onions in their soups or in other ways.

At the same time there are patients who cannot get along without meat, and in such cases pork has seemed the least to augment the proportion of albumen in the urine; hence I have been in the habit of recommending to my albuminuric patients to eat ham, or cold roast pork, and the fatter the better.

Senator counsels fish; I am inclined to think, however, the fish is not a good food in Bright's disease, and that it notably increases the amount of albumen.

The same prescription should be made of cheese, which is a highly azotized nutriment.

As for drinks, it is still milk which you should order to be taken most abundantly, and which you shall insist upon unless its usage is absolutely repugnant to the patients. When milk cannot be taken, you can make use of wine, and especially port, which contains considerable tannin, dilating it with Vals or Vichy

[3] See and compare: Semmola's works, 1800 to 1885; Senator, "On the Hygienic Treatment of Albuminuria" (Berlin, Klin. Woch., December 4, 1882). [6] Bull. Gen. de Th., t. xlv, p. 39.

water; pure wine should be forbidden, as well as brandy and other spirituous liquors. Beer must also be interdicted, as all observers are agreed that the use of beer augments the figure of albumen, and congests the kidneys.

As I am on the subject of drinks, let me call your attention to a potion which Semmola has called "Anti-Brightic," and whose composition is as follows:

Iodide of Sodium	1 gramme.
Phosphate of Sodium	2 grammes.
Chloride of Sodium	6 grammes.
Aqua Fontanæ	1 litre.

The Neapolitan professor recommends that this potion should be drunk every day, pure, or mixed with milk, and claims good effects from it.

Such are the dietetic rules applicable to albuminuria. These rules, it must be borne in mind, are directed by empiricism and are far from having as high value as those which preside over the alimentation of the diabetic. I have given you the reasons before, namely, that the augmentation or diminution of albumen in the urine plays but a secondary role in Bright's disease.

But as the symptoms of uræmic poisoning, whether produced by urea or urotoxine, are augmented by an azotized diet, it seems to me reasonable and physiological for persons affected with this disease to diminish, as far as possible, the usage of azotized substances and to employ instead a vegetable diet and milk.

What result may you obtain from these dietetic rules rigorously carried out? They are very variable, and depend entirely on the greater or less extent of the renal lesions, and also on the nature of the lesions. I have seen in children severe cases of Bright's disease get well, and the most curious instance of the kind was that of a little boy, twelve years old, whom I saw at Compiegne, with Dr. Chevalier; this patient was voiding nearly an ounce (25 grammes) per quart of albumen in his urine. At the time of my visit there were marked symptoms of uræmia present, but at the end of three months, by following a severe dietetic regimen, of which milk, vapor baths, and massage were the principal factors, this young patient completely recovered.

Unfortunately, you are generally called at an advanced stage of the disease, when little can be done, and your duty will consist in an endeavor to keep the patient alive as long as possible, and to prevent uræmic complications. You will be able, in a measure, to attain this end by remembering that the intestine has a vicarious office with regard to the renal and cutaneous functions, and that you may to a certain extent by repeated purgatives relieve the kidneys of a part of their burden, and give issue to toxic materials which accumulate in the blood, thus preventing uræmic poisoning.

— The *Polyclinic* speaks editorially of medical extravagance in the number of societies for medical improvement which exist, and which are a burden to the physician's pocket and time without an equivalent return to him. In Philadelphia a man cannot well avoid belonging to three societies which cost him $25. A heavy assessment from the county society goes yearly to printing the State society's proceedings which are made up with so little censorship that men generally do not take the trouble to call for copies.

MEDICAL EXPERT TESTIMONY, AS GIVEN IN THE COURTS AT PRESENT.[1]

BY A. F. HOLT, M.D.,
Medical Examiner, Middlesex County, Mass.

Another cause which has contributed largely towards bringing about the condition of things we are discussing is the bias of mind with which the expert goes on to the witness-stand, a bias toward the side which has called him. This shows itself the most forcibly where the expert has been the medical attendant in the case, and it is almost the invariable rule in these civil suits where claim is made for damages for injuries to summon such a one, nŏt only to testify to matters of fact that have come to his knowledge by reason of this relation to the claimant or otherwise, but also to examine him as an expert. The human mind is such that I do not believe it is possible for any one, no matter how upright and honorable he may be, to clear himself from this influence so as to become an impartial witness.

The relations of physician and patient are among the very closest and confidential of any in life; the former is the friend the adviser of the latter, and he listens to the story of his injuries and feelings without a thought that it may contain exaggerations or mis-statements, and accepts it as unquestioned truth from which he is to draw his conclusions as to the extent of the injury. While, on the other hand, the patient who has called him expects, as a matter of course, that he will not only take the same view of the case so far as its seriousness is concerned, as he himself does, but, that he will, when he comes to court, present it in the best light for his patient's benefit, that he will keep back what may be damaging to the latter, that the weight of his character, professional reputation, position, influence, in fact everything will all go to favor the interests of his patient, for whose cause he stands there as the champion for whom he is to win the highest possible verdict. The medical man, called into the case simply for the purpose of testifying, has something of this same bias to influence him: and so has the expert called for the defence. It is to witnesses testifying under such a pressure, such a bias, that courts and juries have to look for the solution of questions involving medical science, questions that are, as a rule, the very foundation of nearly all of these suits for damages for personal injuries. Is it a wonder, I say again, that such testimony sometimes falls short of what is expected of it?

This influence which we are considering has another effect on the testimony of experts, and one that must have become manifest to any one who has paid any attention to this subject, and that is this, it leads them, to construct theories favoring their side of the case that do not have the proper data for a basis. Often I have known medical witnesses to draw the most positive conclusions from the existence of a single sign or symptom of injury or the result of injury. Perhaps a single example of this kind of reasoning may make this point clear. A few years ago I was interested on the side of a defence in a case where suit had been brought to recover damages for injuries received from being thrown from a team. The plaintiff, a young man, recovered consciousness soon after the injury,

[1] Concluded from page 496.

and was then sent to a hospital, the record of the case there, being as follows: "Two small cuts on the head, one of them requiring stitching, and a severe sprain of the ankle." He remained there a few days when a plaster-splint was applied and he was allowed to go to his home. The injury to the head was looked upon as a slight one. On account of the injury to the ankle, he was seen once or twice as an out-patient by the hospital authorities, after which he went into the hands of his own physician. This young man, when he came to the witness-stand, after describing the condition of his ankle, which he claimed was still quite lame, testified "that after he had been in the hospital three or four days, he discovered a discharging of bloody matter from one of his ears; that he had never had any trouble with his ear before the injury, and that it was still discharging."

The medical expert, his physician, testified "that this plaintiff had never complained or called his attention to his ear until the night before the trial; that he then examined it, and found the drum extensively ulcerated, disease of the internal ear, and a foul discharge." He gave, as his opinion, "that this young man, at the time of the accident, and as the result of it, sustained a rupture of the drum, and that this occurred by *contre coup*, the cuts being on the opposite side of the head; and further, that he also probably received a fracture of the base of the skull, and that one of these injuries was the cause of the discharge from the ear."

Another expert testified unqualifiedly, "that this man sustained a fracture of the base of the skull as the result of the injury, and that the discharge from the ear came from the inside of the skull." That is, these opinions were founded on one single symptom, and that one described to the experts by the plaintiff, and, of course, an interested party; and furthermore, a symptom by no means a constant one in the case of fracture of the base of the skull, and one, when considered by itself, in no way diagnostic. An expert summoned by the other side testified "that he had made careful examination of this disease of the ear, as well as of the pharynx and nostrils, and that he found pronounced evidences of an old chronic catarrhal inflammation of these parts; and he gave, as his opinion, that the loss of the ear-drum, and the disease of the internal ear was the result of this disease." I might add, by the way, that notwithstanding this man had sworn he never had had any disease, or treatment of the ear prior to the injury, a searching of the records of the Eye and Ear Infirmary soon after the trial revealed the fact that a person of the same name and residence had been so treated in that institution more than two years before. This physician, the medical attendant, said to the expert for the defence, after hearing his testimony: "Why, Doctor, you have damaged our case more than a thousand dollars." Yet this physician stands among the most high-toned and honorable men in our profession, his integrity is above suspicion, and his capacity and training in medicine eminently qualify him to testify as an expert in anything pertaining to his profession. You will ask, I presume, how can one reconcile learning and capacity with such testimony and such conclusions. I answer, simply in this way: this physician had never thought of or even conceived of the high purpose for which he was called into court. It had never occurred to him that he was called there by justice herself to assist in the proper and just decision of the cause in which he was engaged. He had rather looked upon himself as the friend of his patient, who had called him as a witness, and that to him alone he owed allegiance.

So this influence of bias of mind asserts itself in other directions; it leads the medical witness to give undue prominence to minor symptoms, when, by so doing, it will strengthen his side and his theory of the case. It also prompts him to refer all other symptoms, however vague or indefinite, to the original injury. The reasoning and study of the case under this pressure of bias is from an entirely different standpoint from what it would be if one was examining a patient for the purpose of determining the relations of cause and effect and treatment, for, in this case, there is no preconceived theory to support, and every fact weighs for what it is worth in making up an opinion. On the other hand, the expert, under this influence, twists and distorts the facts to suit his theory, although, as a rule, he does this honestly and sincerely, with no thought of wrong-doing. So, in these suits for money damages for personal injuries, whatever may have happened to the claimant between the time of the accident and the trial in the way of sickness, he is sure to claim it as one of the results of the injury, and he usually finds medical testimony to support this theory. In a case that came under my observation some time ago, the party bringing the suit had received a sprain of one of the large joints. Some months after he had an attack of inflammatory rheumatism, and his medical attendant testified "that, in his opinion, the rheumatism was the result of the injury, and that injuries such as this man received (a sprain) was one of the common causes of this disease."

One of my earliest experiences in court was in connection with a case where a woman claimed, as the result of an injury, spinal irritation. Some time after she showed signs of lung disease, and at the time of the trial, these had developed into a well-marked case of what was then called chronic catarrhal pneumonia. As usual, the claim was made that this disease was the result of the spinal irritation. After a long search of works on diseases of the nervous system, I found one or two authors who enumerated, among many other diseases that might result from spinal irritation, disease of the lungs; and on this doubtful authority, three physicians, myself among the number, testified that lung disease might result from spinal irritation.

Had we spent the time consumed in looking up authorities to support conclusions drawn in the interest of the plaintiff in studying the objects of medical expert testimony, I am sure none of us would have been found in the witness-box bolstering up such a theory.

The appearance of the expert witness, as he presents himself on the stand, has much to do with the amount of influence he may exert on the judge or jury. This appearance is, of course, made up very largely of the personalities of the witness, and these are not proper matters of criticism or discussion. But there are certain other faults that are not uncommon to the medical expert that not only detract from his good appearance, but also seriously lessen the weight of his testimony. One of the most common of these faults is lack of attention to the interrogatories put to him. It is not uncommon to hear a medical witness ask the questioner, and particularly one that is a little embarrassed, to repeat the inquiry, and sometimes this

request is even repeated in connection with the simplest question. This fault does not come from lack of comprehension, but rather from inattention. The witness hears the first part of the inquiry, then his mind begins to formulate the answer, and when he is ready to reply, he has really forgotten what he is to answer. So, sometimes, one answers without a clear understanding as to what the inquiry is, and such a course is almost sure to get him into trouble. Also, in cross-examination, a question is put in such a way that the correct answer is apparent to everybody, and still that answer does not convey the honest opinion of the expert in relation to the subject under inquiry. Some witnesses evade such a question, either by discussion with the attorney, or by making an indefinite evasive reply, but the questioner is sure to press the matter, and the expert must, as a rule, in the end answer it as the attorney intended he should, and he usually winds up such a contest by asking the witness "why could you not answer that in the first place?" A better way to treat such questions is to answer at once, and then to ask for an opportunity for an explanation; this is always granted, and under this broad authority anything in relation to the matter can be set right. If one pursues the former course, he often, although very unjustly, gets the reputation of being an unfair and one-sided witness.

These causes that have been discussed in the last few pages, seem to me to be among the most prominent of those that have contributed largely toward lowering the position of the medical expert witness, and these can fairly be laid at the door of the medical profession, but this profession is not responsible for all the sins that are heaped upon the head of the medical expert, for the legal profession has its share of responsibility for bringing this witness into such disrepute, and that share is a very large one. The attorney who brings one of these suits for damages for personal injury, is sure to try and procure the kind of medical testimony that will put the damage done to the body of his client in the strongest possible way. He not only drills his medical witness in the art of testifying, but by skilled argument he tries to impress him with his own ideas as to the extent or nature of the injury, and whether he succeeds in this or not, when he gets into court, he knows just how far to go in his questioning, being sure to bring to light only such facts as will help his side of the case. So the cross-examiner of one side or the other puts his inquiries with the sole object in view of getting responses that will strengthen his side. The attorney for the plaintiff formulates his hypothetical questions with all the skill and ingenuity of which he is master, not for the purpose of getting facts that will lead to correct and just conclusions, but with the idea of getting testimony that will lead to the largest money verdict. What wonder, I say once more, is it, that he often leads the medical witness to appear as a partizan, rather than as instructor of the court?

Now we come to the most difficult part of this question, and that is, what is the remedy? How can we remove this dark blot from the otherwise fair fame of the medical profession? The short-comings that I have mentioned that the medical witness reveals on the witness-stand, can only be overcome by individual effort, assisted by the medical fraternity as a body. But the great fault, the foundation of the whole matter, lies deeper; in fact, it is in the custom itself, as it stands to-day. How can this be improved? Some have suggested that medical expert witnesses be summoned by the justices of the court. This plan would no doubt greatly improve medical testimony; it would certainly do away with the bias men have, who are called as they are to-day. The justices of the courts of Massachusetts have ever been men of honor and integrity, still they are not free from the influences that make men entertain visionary and unsustained views in relation to many matters of science. Only last winter I heard one who had held the position of a judge in one of our courts for more than a quarter of a century, testify before a committee of the legislature in opposition to a bill regulating the practice of medicine, "That he knew of a case where a boy was seriously shot in the abdomen, the charge entering the peritoneal cavity and producing serious bleeding; the boy's mother placed her hands upon the wound, and by reason of some peculiar power she possessed, the bleeding ceased and the wound healed;" he further testified, "That the boy would have died at once, had it not been for this treatment." A justice holding such notions of medical practice and surgery, would not, I fear, be very judicious in making his selection of medical experts.

The principal objection to this suggestion, is to my mind, however, that it is impracticable, for this reason: there is no probability that the necessary legislative action to bring about this change, could be procured, as a move in this direction would arouse the opposition of a large majority of the rank and file of the legal profession, they knowing that the basis of these claims for damages for personal injuries and their support before the courts, depends very largely upon the medical testimony, and just such testimony as they are able to get under the present system, and furthermore, I am sure the people would look upon such legislation as an effort to take away one of their rights.

It has also been proposed that the courts be empowered to call experts, and still allow the parties to the suit to put in such medical evidence as they may desire. I do not see how such a plan would improve the matter. It is often the case now that clear and well-founded medical opinions are given in the courts, opinions as able and trustworthy as could be procured from any expert, no matter by whom summoned, but the difficulty is in these cases where such opinions have been given, the other side calls a medical man who arrives at a different conclusion, and supports his opinion by what seems to be, to the unprofessional mind, as plausible argument as that of the expert of the other side. Who are the jury to believe? The expert summoned by the court? or the one called by the parties themselves. The advocate on the one side argues that the witness that gave testimony favoring his view of the case, ought to be believed, and so does the advocate on the other side. The presiding justice can lay down the principles of law, but he cannot prescribe who is to be believed, and not believed, for that is a province of the jury, and a question they must always settle, therefore, it seems to me clear, that the carrying out of such a suggestion, would leave this matter of expert testimony just where it now stands.

There are no doubt other plans requiring legislative action, that would correct this matter and put the medical expert in his proper place before the courts, and give to medical testimony the respect and weight to which it is entitled, but the present custom is so thoroughly bound up in our judicial system, I do not

believe that any such could be devised that would not arouse sufficient opposition to ensure its defeat. I am satisfied that whatever is done in the near future, at least looking to the removal of this dark stain from this great and otherwise honored profession, must be done in our own ranks by both combined and individual effort.

The last quarter of a century, so far as the development of medicine is concerned, has been the grandest in all its two thousand years of history, and in that short time it has advanced a long way over the road that leads from the darkness, the groping and uncertainty of the practice of an art toward the broad, bright daylight of exact science, until the teachings of to-day are founded on the results of observation and experiment, rather than on those of speculation and theory as formerly. In this grand march, surgery, chemistry, physiology, pathology and sanitary science, have all taken part, and now Theory and Practice is beginning to feel this influence that has pushed the other branches of medical science so well forward, and *it* is moving in the same direction. Certainly there never was a more opportune time than the present for the medical profession to develop medical jurisprudence, and that by a more careful study of its duties and responsibilities and by a just appreciation of its high importance in both civil and criminal causes. By so doing we shall not only bring credit to ourselves, but add another benefit to the long list the world already owes to medical science.

NOTES ON THE TREATMENT OF STONE IN THE BLADDER.[1]

REPORT OF TWENTY-FOUR CASES. RECURRENCE OF STONE. LITHOLAPAXY IN THE FEMALE BLADDER. FISTULA AFTER LATERAL LITHOTOMY. CALCULUS WITH SHOE-STRING NUCLEUS. STRICTURE OF THE URETHRA COMPLICATING LITHOLAPAXY.

A. T. CABOT, M.D.
Surgeon to the Massachusetts General Hospital. Surgeon to the Boston Children's Hospital

IN no branch of surgery has there recently been so complete a change of practice as has come about in the treatment of stone in the bladder. Within the past eight years, two operations have come to the front and have rapidly superseded the older methods. Of these, one, litholapaxy, is new, and the other, supra-pubic lithotomy, although old, was not formerly in good repute. A brief review of the steps in this radical change may be of interest, and will serve as an introduction to a short series of cases treated in accordance with modern ideas.

Ten years ago, it was the generally received practice among those who might be regarded as authorities in this branch of surgery, to crush only those stones which could be satisfactorily disposed of in three or four sittings by the lithotrites then in use. So great was the fear of instrumentation in the bladder, that it was thought important for these sittings to be very short (from three to four minutes). Evidently, therefore, the stones considered proper for lithotrity were small or soft. Larger and harder stones were submitted to lithotomy, and the lateral operation was the favorite one for these cases. The central perineal operations had some strong advocates, but were only useful for stones of moderate size.

[1] Read before the Boston Society for Medical Improvement, November 23, 1886.

Supra-pubic lithotomy was generally looked upon as a dangerous method, only to be resorted to with stones of large size which could not be safely dragged through the perineum.

At about the time of which we are speaking, the antiseptic method of treating wounds came to a general adoption and the consequent improvement in the results after lithotomy was so considerable as to threaten to place still closer limits to the field of lithotrity.

In the year 1878, Dr. H. J. Bigelow published his first paper introducing the operation of Litholapaxy, which was rapidly adopted, and is to-day the generally accepted method of dealing with the great majority of cases. With the efficient lithotrites and evacuator which made "lithotrity at one sitting" possible, it is now usual to remove stones of considerable size and hardness, and practically it has been found that under ordinary conditions in adults, any stone which is suitable for lateral or other perineal lithotomy is suitable for litholapaxy, and that even stones so large that they would require a supra-pubic incision if they were removed by the knife, may, when soft and friable be safely crushed and pumped out.

The exceptional cases in which litholapaxy cannot be used are as follows: (1) A very large and hard stone may resist every attempt at crushing. (2) A stone may have as a nucleus a foreign body, such as a piece of necrosed bone or a bullet, too hard to crush and too large to come through a tube. (3) An encysted stone may be out of reach of the lithotrite. (4) Some writers consider that stricture of the urethra may prohibit litholapaxy. This cannot often happen, for strictures, however close, yield readily to divulsion which may be immediately followed by the crushing and evacuation of the stone. I have so often seen these two operations successfully done together on an etherized patient, that I can but think this the best practice. While it economizes time, it saves the patient much needless manipulation. (5) False passages may exist, which so interfere with the introduction of instruments that the dangers of the operation are greatly enhanced, and the question of lithotomy is to be entertained. (6) The hip may be anchylosed, in a position which interferes with the use of urethral instruments.

It at first seemed unlikely that "lithotrity at one sitting" would ever be applicable to children. Before puberty the urethra is so small that instruments of any considerable size cannot be used through it. Quite recently, however, Dr. Keegan,[2] of India, has published a series of fifty-eight cases of stone in children, in which he used litholapaxy, and with only one death. Such results must command our attention and make us reconsider the matter, although it is hard to believe that the present very low death-rate after lithotomy in children can be improved upon.

In any of these exceptional cases to which litholapaxy cannot be applied and in which a cutting operation is required, we have, as has been said, three general methods to choose from. The median perineal, the lateral perineal, and the supra-pubic operations.

Median perineal lithotomy, in which the membranous urethra is opened, and the prostate then either dilated or incised on the middle line is only applicable to small stones, and finds but little use at the present time. In case of a foreign body of small size, it might be employed.

Lateral lithotomy has a much wider field, being

[2] Indian Medical Gazette, May, 1884.

competent for the removal of stones of considerable size. It has the disadvantage of necessarily wounding the urethra and prostate, at the same time putting the seminal ducts and rectum in danger. It also exposes the patient to certain risks from hæmorrhage.

On the other hand, owing to the dependent position of the wound, it has the decided advantage of providing thorough drainage to the bladder.

In the treatment of stone in children lateral lithotomy has had its greatest success, the death-rate being very low (from five to seven per cent). Dr. Freyer has even achieved the feat of completing one hundred and forty-three operations without a death.

Lastly, we come to the supra-pubic operation, with the recent great improvement in its technique.

In the year 1878, which was an eventful one in the history of stone operations, a few months after the publication of Professor Bigelow's monograph, there appeared in the *Edinburgh Medical Journal*, an article by Dr. Garson, upon the influence which distension of the rectum had upon the position of the bladder and the pre-vesical fold of peritoneum. This paper attracted but little attention at the time, but was followed two years later by another upon the same subject by Petersen, in the *Verhandlungen der Deutschen Gesellschaft für Chirurgie*, 1880.

These observers showed that by filling the bladder with water and then distending a colpeurynter introduced into the rectum, it was possible to lift the parts so as to very materially raise the peritoneum and thus widen the space between it and the pubes through which the bladder could be reached. The distension of the rectum pressed the bladder forward and held it firmly against the abdominal wall, so that it could be easily recognized and readily opened. It also, by raising the vesical floor brought all parts into easy reach of the finger and eye, making thorough exploration possible.

By the previous methods of operating, the two principal dangers were: *first*, of wounding the peritoneum; and *secondly*, of infiltration of urine with septic processes starting in the wound. The first of these dangers was one which could be avoided with care, but, this very care in separating the parts, and bringing the bladder into view, opened the cellular spaces about and greatly increased the danger of septic absorption. The new method not only rendered the danger to the peritoneum more trifling than it had been before, but also by bringing the bladder into easy reach rendered much manipulation unnecessary and made it possible to open it by a clean, direct incision without interference with its cellular surroundings.

The German surgeons quickly put this improvement into practical use, and the operation became at once a popular one with them; It was almost simultaneously adopted in France and soon found its way to England and to this country. So firm a hold did it take upon the German mind, saturated with an enthusiasm for antiseptic surgery that at Magdeburg in 1884, Volkmann of Halle, who was one of Lister's earliest and most strenuous advocates, declared it as his belief that lithotomy was the proper operation for stone, and that "the various methods of crushing only deserved a place in the history of medicine." He was supported in this view by Bergmann: their opposition to litholapaxy being based on the supposition that it could be successfully practised only by especially skilful and experienced surgeons.

This theoretical position was ably opposed by Professor Dittel and others of large experience in genito-urinary surgery, who held the same high opinion of litholapaxy that prevails in France, in England, and in this country. The best answer to so speculative an opinion as that of Professor Volkmann, is, however, an appeal to facts; and the lithotomist who hopes to establish his pet operation in advance of all others for the treatment of stone, must show that it is capable of saving more than ninety-seven per cent. of ordinary adult cases, for this is about the percentage of recovery after litholapaxy.

From this brief sketch it will be seen of how recent a date are the two operative procedures for the treatment of stone in the adult, that now meet with the most favor, and which have within six years to a great extent displaced the perineal operations, that up to that time had been in highest repute. The modern treatment of stone in the bladder may then be briefly summarized as follows:

Litholapaxy is to be used in all ordinary adult cases. How far this operation can be applied to children is still doubtful.

Supra-pubic lithotomy is to be employed in cases where the stone is too large and hard to be crushed, or when an impervious stricture makes the introduction of a lithotrite or staff impossible. In case of an encysted stone the high operation is also the best, as the thorough inspection of the bladder which it makes possible, enables us to treat the condition intelligently.

Perineal lithotomy may be reserved for occasional use upon stones of moderate size where false passages or anchylosis of the hip make litholapaxy impossible or when a stone has a foreign body as a nucleus. It is possible that the supra-pubic incision may eventually prove to be the best for even these cases; but at present the percentage of recovery after lateral lithotomy, in cases of small calculi, is better than the high operation can, or at any rate has, produced.

The treatment of stone in children is just now more unsettled than in any other class of cases. Litholapaxy and supra-pubic lithotomy are both putting in their claims, but thus far the best authentic results are from lateral lithotomy. Dr. Keegan's results from crushing are, it is true, better than the average results from the lateral operation; but until they are confirmed by other operators, they must be looked upon as exceptional and are far excelled by Dr. Freyer's success with lithotomy (one hundred and forty-three cases without a death). Whether supra-pubic lithotomy can accomplish something better still, has not been shown.

REPORT OF TWENTY-FOUR CASES.

The cases to which reference will be made in this paper are twenty-two in number, and comprise all of those operated upon by the writer up to this time. Twenty of these operations were by litholapaxy, one by lateral lithotomy and one by supra-pubic lithotomy.

The following table gives the essential facts in regard to them.

It will be seen that in but one case did death follow the operation, and I will give that patient's history somewhat at length.

M. M., a laboring man, sixty-nine years of age, entered the Massachusetts General Hospital January 20th, 1885. He gave a history of frequent, painful

micturition with an occasional sudden stoppage in the full stream, hæmaturia and pain on riding in a wagon. These symptoms had existed for about a year, and Dr. H. E. Marion, of Brighton, had sounded him, and detecting a stone, had sent him to the hospital. The patient was a feeble old man with a weak pulse. An examination of the urine showed nothing beyond alkaline fermentation with purulent sediment. By the kindness of Dr. Bigelow, in whose ward he entered, I operated on January 21st. The stone was small and soft, weighing only ninety-eight grains, and the lithotrite was introduced but twice. On the following day he was very comfortable, was passing urine in good quantity, and had no tenderness or discomfort about the bladder. He had, however, a troublesome cough with profuse purulent expectoration.

January 25th, his cough was worse. Abundant sonorous and sibilant râles were to be heard over both sides of his chest with fine moist râles over the right lower front. There was considerable dyspnœa and his breath was very foul. The urine was almost clear and he had no bladder symptoms whatever.

From this time the condition of his lungs gradually became worse and he finally died on the 30th of January, nine days after the operation. No autopsy was allowed, but clinically it was evident that the fatal issue resulted from bronchitis and secondary pneumonia, and that his bladder was in good condition at the time of his death.

In only one case (No. 11), did any serious symptoms result directly from the operation. This patient was a man of sixty-seven, and infirm for his age. I saw him in October, 1885, in consultation with Dr. J. P. Reynolds, who kindly transferred him to my care.

For one and a half years he had had frequent, painful micturition, with a good deal of pain through the penis, which was greatly aggravated by riding. For the previous eight months he had had frequent attacks of hæmaturia. Otherwise the urine was that of an ordinary cystitis. For a long time he had lived alone, and, eating but little, had gradually acquired the habit of taking a good deal of stimulant, often more than a pint of whiskey in a day.

The sound touched a stone and on October 23d, 1885, I operated by litholapaxy under ether. A hard, uric-acid stone of good size was crushed and removed. At the first use of the evacuator, a sharp, angular fragment caught in the eye of the tube and scratched the urethra considerably in its withdrawal. With this exception the operation went smoothly and at the third pumping, the bladder was found to be empty. On the following day there was a considerable rise of temperature (102.5° F., in the evening), and on the second day after the operation it rose to 104.5° F. At this time no casts could be detected in the urine.

On the fourth day the temperature fell to about 100° F., but on the fifth day it again suddenly rose to 104.6° F., at night, and the patient became delirious and tremulous. On this day an epidydimitis started in the right testicle. On the sixth day, the fever continuing, the urine contained a trace of albumen and a few hyaline, granular and epithelial casts.

It was now found that by increasing the amount of stimulus to about a pint of whiskey a day, the tremulousness and delirium could be controlled. As the epidydimitis subsided, the fever slowly left him and the casts and albumen disappeared from the urine. Convalescence, although tedious, was steady, until he left the Hospital, six weeks from the time of operation.

(To be continued.)

REPORT ON PROGRESS IN OPHTHALMOLOGY.

BY O. F. WADSWORTH, M.D., AND MYLES STANDISH, M.D.

STILLING[1] asserts that no one of the theories of the cause of myopia hitherto formulated has taken firm root. The accommodation theory is now generally disbelieved. There are strong arguments against the convergence theory; Arlt has pointed out that staphyloma is never developed in convergent strabismus; and myopia and staphyloma have developed in eyes which never had binocular vision.

The chief element in the production of myopia is to be sought in the action of the muscles, and especially in that of the superior oblique, which, with the inferior rectus, is in a state of continued contraction during near work. Examination of fifty eyes *in situ* showed that the course and insertion of the superior oblique is extremely variable, and its action, therefore,

[1] Bericht der Ophthalmologischen Gesellschaft, Heidelberg, 1881.

very inconstant. It may run nearly transversely, or so obliquely as to approach a median direction; may be inserted far from the optic nerve, or send prolongations close up to the nerve or to its outer side. According to these variations, contraction of the muscle either causes compression and dragging, compression or dragging alone, or neither of these effects. These observations awakened the idea that the constant pressure of the muscle in reading and writing during the period of growth of the eye might produce myopia, and that the variations in direction of the staphyloma and in the shape of the disc might be explained by the different insertions of the obliquus tendon. To decide this point a second series of fifty eyes was examined in company with the anatomist Pfitzner, and it was demonstrated that the course and insertion of the obliquus was in close correspondence with the form of the eye and the shape of the disc. Stilling states that it is a mistake to consider the normal eye a quite regular structure; that this is true only of the anterior portion, but behind the ciliary body there are often irregularities of shape.

Further, a number of myopic eyes were examined. Two of these were of special interest because the refraction during life (M. 5 D.) was known. The only abnormity in these eyes was a slight enlargement of the outer part and a corresponding distortion of the papilla. These eyes were normal, the moderate increase in length was in exact correspondence with the insertion of the obliquus. One was 25 mm., the other 26 mm. long, yet both had the same refraction. This fact led to the measurement of the radius of curve of the cornea in a number of myopic eyes to determine its influence. In the weaker degrees of myopia it was found larger, in the higher degrees smaller. The curve of the cornea, Stilling believes, determines the degree of the myopia.

The ordinary myopia, Stilling concludes, is due to the influence of pressure during growth; but such a myopia is not disease; the eye is not diseased, but only slightly deformed.

It is different with the highest degrees of myopia; there is disease, a hydrophthalmus; yet the eyes are not diseased because they are myopic, but myopic because they are diseased. It is only in such diseased eyes that the widening of the space between the nerve sheaths and the separation of the outer sheath from the sclera is found. The two forms of myopia should be distinctly separated.

In the discussion which followed the reading of Stilling's paper, Cohn, while protesting against the view that the so-called school-myopia was not important as a disease, agreed with the opinion expressed that all the theories of the cause of myopia were unsatisfactory. Against the convergence theory particularly he adduced his recent investigations of watchmakers. He had examined one hundred watchmakers in Freiburg who never used the magnifying lens. These men worked on the finest machinery, pivots, screws of 1–2 mm. diameter, twelve hours daily; their eyes were generally but six inches from their work. Yet in spite of all this, only three of the hundred had during many years' work acquired myopia, and in the three it was only of small degree. The light was indeed excellent, but although converging excessively all day, and beginning at fourteen years of age, an age at which myopia often begins at school, these men had not become myopic. He had also examined a large number of seamstresses who had been occupied for years all day long over the finest embroidery, and found none myopic. Furthermore, it was a matter of common observation that proportionally very few myopic tailors present themselves at the policlinics. It was a probability that he had already suggested, that the close observation of small but fixed objects, as is the habit with watchmakers, is less harmful to the eye than the following of the lines in reading, writing and drawing, with the ocular movements which these occupations necessitate.

MEANS FOR THE PREVENTION OF MYOPIA.

Priestly Smith[2] in an article on "Means for the Prevention of Myopia," enumerates the following essentials for a school desk:

(1) The seat must be of such a height as will allow the scholar's feet to rest flat on the floor or footboard, and broad enough to support the greater part of the thigh.

(2) The seat must have a back placed at such a height as to fit the hollow of the back below the shoulder-blades, and support the body in a vertical position.

(3) The near edge of the desk must be just so high above the seat that when the scholar sits square and upright, with elbows to the sides, the hand and forearm may rest upon the desk without pushing up the shoulder.

(4) As used in writing the desk must have a slope of ten to fifteen degrees (about 1 in 5); as used in reading it must support the book at an angle of about forty-five degrees, and at a distance of at least twelve inches from the eyes — sixteen inches is better.

(5) As used in writing, the edge of the desk must overhang the edge of the seat by an inch or two, in order that the scholar shall not need to stoop forwards, and that the support to the back may be maintained.

(6) Either the desk or the seat, or some part thereof, must be movable at pleasure, so that although the desk usually overhangs the seat, the scholar may be able at any time to stand upright in his place.

(7) The desks and seats must be of various sizes, in order that the foregoing conditions may hold good for scholars of various ages.

DIRECTION OF LYMPH STREAMS IN THE EYE AND THEIR INFLUENCE IN SYMPATHETIC OPHTHALMIA.

Gifford[3] reports the results of forty experiments on rabbits undertaken for the purpose of determining the direction of the lymph streams in the eye. The results obtained were definite and constant.

A small drop of sterilized water containing india-ink or cinnabar in suspension was injected into the vitreous. There was generally little or no reaction, and on the next day or later, the particles could be seen, by the use of the ophthalmoscope, collecting in the optic excavation, and if the animal was killed a day or two after this, the microscopic examination of longitudinal sections of the optic nerve showed the whole course of the central canal marked by a line of the pigment, which passed out of the nerve with the vessels and could be traced toward the rear of the orbit.

Microscopically it could be seen that the granules were contained in the lymph spaces around the vessels, partly free, and partly enclosed in connective tissue corpuscles and the occasional leucocytes. Besides the

[2] Ophthalmic Review, June, 1886.
[3] Archives of Ophthalmology, 1886, p. 153.

granules along the main trunks, they were also present along all the smaller branches which radiate into the choroid and, farther back, into the periphery of the nerve. When the pigment was introduced near the posterior pole of the eye, it was discharged very promptly. The farther forward the injections were made, the longer the time required for the powder to reach the papilla, and the smaller the proportion of free granules. Outside the optic nerve the pigment kept close to the sheaths of the vessels and was traced to the posterior end of the orbit; here in all probability it entered the cranial cavity through the sphenoidal fissure. A small quantity of anthrax culture was injected into the posterior portion of the vitreous, and on the following day an exudation could be seen filling up the optic excavation and often concealing the papilla. The bacilli followed precisely the same channels as those into which the granules were carried, except that they did not enter the finest channels. As they multiplied wherever they were carried, they were found in considerable numbers in the orbit. From here, as will be shown in what follows, they were carried down into the intervaginal space of both nerves. These experiments were repeated on cats, dogs, and guinea-pigs, and, ophthalmoscopically, the accumulation of granules on the papilla was observed in these cases as in the experiments upon rabbits.

In regard to the lymph stream in the intervaginal space, our author's experiments were entirely confirmatory of Quincke's in 1872. The latter trephined the skull and injected cinnabar in suspension into the subdural space of rabbits and dogs: he found that the powder, besides reaching the spinal canal, was invariably carried down in considerable quantities, sometimes within a few hours, between the optic sheaths in both subdural and subarachnoidal spaces to the globe. The greatest quantity was always found next the eyeball. Cinnabar, anthrax bacilli, and blood, brought down in this manner from the cranium to the globe, are severally carried out into the orbit by the posterior vitreous stream. On the other hand, this latter shows not the slightest tendency to pass into the subvaginal space. With regard to the passage into the supra-choroidal space, it was noted in three cases that anthrax bacilli carried down between the sheaths from the brain, could be clearly traced for half a millimetre between the choroid and sclerotic. With regard to the outflow from the vitreous around the lens, our author reserves his experiments for another paper, but states that "the results of the experiments already made, have convinced me, rather against my will, that besides the posterior vitreous stream there is also an anterior stream flowing forward around the lens; as is, of course, generally accepted.

Gifford[4] follows this article by another upon the influence of these lymph streams in the propagation of sympathetic ophthalmia.

Deutschmann, as is well known,[5] by injecting into the vitreous of rabbits the ordinary white and yellow pus-cocci, was able, almost without exception, to obtain well-marked sympathetic neuro-retinitis of the fellow-eye. The time required for its development varied from a few days to three weeks. With the microscope the micrococci could be traced from one eye to the other by the way of the optic nerves, their sheaths, and the chiasma.

[4] Archives of Ophth., 1886, p. 280.
[5] See Journal, Vol., xiii, p. 176.

Our author failed altogether to obtain an unquestionable inflammation in the fellow-eye in twenty-one cases in which he inoculated the vitreous of rabbits with pure cultures of pathogenic cocci. Staphylococcus pyogenes aureus was used in nine cases; staphylococcus pyogenes albus in eight cases; and streptococcus pyogenes albus in four cases. The inoculated eye invariably underwent a severe inflammation, which generally became chronic and ended in more or less pronounced phthisis. The microscopic examination showed, according to the stage, the vitreous chamber filled with a purulent or semi-caseous exudation, and the layers of the choroid pressed apart by a dense infiltration of round cells; the deep physiological excavation plugged with the same; and the retina, more or less thoroughly disorganized. The lymph spaces around the central vessels of the optic nerve, the orbital tissue below the nerve itself, for a distance of 3-4 mm. back of the eyeball, were all markedly infiltrated with round cells. The orbital tissue and the pial sheath were especially strongly affected in the neighborhood of the exit of the central vessels from the nerve into the orbit.

The difference between Deutschmann's observations and Gifford's, is as follows. Deutschmann describes the micro-organisms as occurring all through the first eye and in both optic nerves and their sheaths, without mentioning any special relation to blood or lymph vessels. In Gifford's cases they were generally limited to the vitreous of the inoculated eye, occurring in greatest numbers in the exudation just before the papilla and just behind the zonula. In no case were they found farther back than the bottom of the physiological excavation. In the infiltration filling the central canal, along the small vessels of the nerve, in the sheaths, subvaginal space, and orbital tissue, he searched for them long and in vain. Why the micrococci are not swept out into these canals and spaces, as it has been shown in the previous paper, particles of india-ink and cinnabar are, depends, in all probability, on the choking of the lymph vessels with leucocytes, which was a marked feature of all these cases.

Convinced by these experiments that with the rabbits obtainable at Erlangen and Zurich, it was practically impossible to produce sympathetic ophthalmia with a fungus that excited a quick and strong reaction, and equally convinced by experiments with amorphous powders that a micro-organism capable of living in the lymph without exciting too intense an inflammation, must of necessity be carried around from one eye to the other, our author found such an organism in the bacillus of anthrax. This bacillus Gifford succeeded in tracing from the vitreous of one eye around to the perichoroidal space of the other, although the course was completed in but three out of twenty-five cases, owing to the rapidity with which the animals die when the subconjunctival tissue is inoculated, and in making injections into the vitreous, it is exceedingly difficult to avoid such inoculation.

We must now consider how far these results can be used in explaining the phenomena of sympathetic ophthalmia in man. First, with regard to the lymph stream from the vitreous, our author assumes that a condition occurring in animals so widely separated as cats and rabbits, also exists in man, there being no anatomical peculiarities to make it unlikely. This also holds good of the stream in the intervaginal space. When, however, we come to the passage from the

latter into the space around the choroid, we have the well-known fact that the supra-choroidal space can be injected from the intervaginal space with ease; the papilla and retina, on the contrary, with difficulty or not at all. With regard to the clinical history of these cases, the most difficult point to explain is why we have no cranial nor orbital symptoms in sympathetic ophthalmia if the micro-organisms pass through these cavities on the way to the second eye. Our author's explanation is that there undoubtedly is a slight lymphangitis in the orbit and meningitis at the anterior part of the base of the brain, but that the lymph stream generally keeps the micro-organisms from collecting in sufficient numbers to do serious mischief at these points, and he reminds us that certain pathogenic bacteria, as pus-cocci, pass from one part of the body to another, producing merely a slight lymphangitis on the way, and causing no severe inflammation until they accumulate, as, for instance, in the lymphatic glands.

The fact that in so many of these experiments the posterior lymph channels were quickly closed against the passage of micrococci, Gifford thinks explains the non-occurrence of sympathetic trouble in many cases where the primary inflammation in the first eye is violent. Leber and Deutschmann have sought the explanation of this non-occurrence after panophthalmitis, in the supposed destruction of the fungi by the violence of the suppuration and in the emptying of the infectious contents when the eye bursts.

INNERVATION OF PUPIL AND CILIARY MUSCLE.

Mr. Jessop [5] has brought forward arguments to show that the fifth nerve is concerned in some of the functions of the pupillary and ciliary muscles. The pupil not only contracts when the ciliary muscle does so, but also dilates when the latter relaxes; the latter act, Mr. Jessop states, is carried out through the intermediation of the long ciliary nerves from the nasal branch of the fifth. The ordinary light-reflex of the pupil takes place through the agency of the third nerve; and the cervical sympathetic, as the inhibitory nerve, causes the dilatation of the pupil. In mammals the two chief motor functions of the pupil are thus separated; whereas in birds, possessing voluntary control over the irides, this is not so, for the cervical sympathetic has no control over the pupil, the nerve causing dilatation being the fifth. Mr. Jessop draws a clear distinction between the modes of action of cocaine, eserine, and atropine on the neuro-muscular intra-ocular apparatus. The first of these agents acts on the terminations of the cervical sympathetic in the iris, and probably of the fifth in the ciliary muscle; whilst the action of the other two drugs is on the muscular tissue directly. Hence it is that, even after section of all the nerves going to the intra-ocular muscles, atropine and eserine can cause further dilatation or relaxation, and contraction, respectively.

NEURO-RETINITIS IN BRIGHT'S DISEASE.

C. S. Bull [6] in an article upon exudative neuro-retinitis associated with chronic Bright's disease, says that the period of duration of the disease, when the eyes were examined, as indicated by the occurrence of the symptoms, was very difficult to determine. Of the 103 cases observed, in 56 cases, or more than 50 per cent., it was entirely unknown. In 47 cases, or somewhat less than 50 per cent., it varied from six months to several years. The sex of the patients was nearly evenly divided, 56 being men and 47 being women. The vision ranged from $\frac{20}{20}$ to zero. It was improved in 32 cases, or about 31.5 per cent., but this was mainly due to improvement in the renal disease and in the general health, for, as the disease in the kidneys reasserted itself and the general health failed, fresh exudation, or hæmorrhages, or both occurred in the retina, and vision again deteriorated. Uræmic amblyopia or transient attacks of more or less complete blindness in one or both eyes occurred in 37 cases, but in all these cases there was retinitis or neuro-retinitis. Both eyes were affected either at the time of the first examination or subsequently in ninety-three cases. Both optic nerve and retina were inflamed in both in about 25 per cent. of the cases. In 34 cases there were no hæmorrhages. In 30 of these 34 cases there was hypertrophy of the left side of the heart, while among the 69 cases in which hæmorrhages occurred there were five in which there was no cardiac disease demonstrable. The retinal hæmorrhages were associated with a diseased condition of the bloodvessels.

Bull examined these cases with special reference to the duration of life, and was impressed very strongly with the extremely unfavorable prognosis to be made, and with the comparatively short lease of life which these patients still possess. Of the 103 patients examined, extending over a period of thirteen years and six months, 86 have died and 17 are still living. Of the 86 who have died, 57 died within the first year; 18 within the second year; six within the third year; four within the fourth year; and one within the sixth year. Of the 57 who died within the first year, 30 died within six months. Of the 17 patients who are still living, 14 were seen for the first time within the last six months, and in all but one of these fourteen the renal disease had probably lasted a long time. Two of those still living were first seen within the past year, and one of the seventeen was first seen seven years ago and has been examined at intervals since.

PARALYSIS OF INTRA-OCULAR MUSCLES AFTER DIPHTHERIA.

Remak [7] writes as the results of the observation of 100 cases of post-diphtheritic paralysis of the intra-ocular muscles that the amount of the paralysis varied greatly. In some cases it was so light as only to bring to the surface a certain amount of latent hypermetropia, and in some it required +4.00 D. to enable the patient to read small test letters at ten or twelve inches. He divides his cases into three classes: severe, requiring from +3.00 D. to +4.00 D. to read with, as above; medium, requiring +1.50 D. to +3.00 D.; and light, needing less than +1.50 D. Dividing his cases as above, he classifies 24 cases as severe, 16 cases as light, and the remaining 60 cases as of medium severity. He states that severe paralysis sometimes follows a very mild attack of diphtheria, and that the converse is also true.

In these 100 cases there was not a single case of optic neuritis.

Clinical Memorandum.

SPONTANEOUS FRACTURE OF STONE IN THE BLADDER.[1]

BY F. S. WATSON, M.D.

THESE fragments of stone were taken from the bladder of a patient of eighty years of age, after death, who, for some years previous, had been the unconscious subject of hypertrophy of the prostate until ten days before his admission to the City Hospital, when he had an attack of retention of urine, following exposure to wet and cold. He was relieved by catheterization, and had no further trouble until the day before his entrance to the hospital. He then had another attack of retention; a catheter failed to pass into the bladder, and a false passage was made in the prostatic urethra in the attempts to introduce it. He applied at the hospital for relief, and after some difficulty, owing to marked obstruction in the prostatic urethra, a silver catheter was introduced and allowed to remain in the bladder, through which was gradually drawn off a large quantity of bloody alkaline urine. Shortly after this the patient developed urinary fever, and died in a week.

At the autopsy, the bladder was found to be thickened and trabeculated, the prostate hypertrophied, both centrally and laterally. Behind the greatly enlarged third lobe, was a deep *bas fond*, formed by the bulging downward of the floor of the bladder, in the bottom of which lay the fragments of stone herewith shown. The mucous membrane of the bladder was the seat of a hæmorrhagic cystitis, and in places, also of a diphtheritic membrane. The pelves of the kidneys, and the organs themselves were occupied by an acute inflammatory process.

The pieces of stone had peculiar characteristics, which at once attracted attention, and suggested, in the absence of a sufficient mechanical force from without, that their fragmentation was the result of spontaneous fracture. As cases of this sort are rare, I have thought it worth while to show this one as an example.

The weight of the whole mass was one hundred and sixty grains, and it is composed almost wholly of uric acid. Much of the stone consists of bits having no clearly-defined form, and of sand; the rest of fifty-six pieces, varying in size from a quarter to a whole good-sized pea. Eight of the latter are represented in the accompanying photograph (enlarged three diameters), and fall, as to shape, into two groups, the first having the appearance of parts of an outer shell, or surface of a sphere, which has been cracked off, and present a convex and a concave surface, as in the specimen marked 1. The remaining fifty-two fragments show for the most part a smooth, convex back, projecting forward from which is a two, three, four, or many-sided body. The surfaces of these sides show a great similarity, and some of them can be made to very nearly fit into each other, and evidently would do so quite exactly in some instances, had not their angles and edges become somewhat rounded from having received a deposit upon them subsequent to their having separated. Four, however, were found which had fresh surfaces, showing a more recent splitting apart, which fitted each other in pairs precisely (one pair is numbered 2 in the accompanying photograph). The segmentation in this case seems to have taken place in two ways: by clefts radiating from the centre, and by the separation of the outer crust or layer from the one below it. These processes are indicated in the bits numbered 3 and 4.

The introduction of a silver catheter was the only force which could have acted upon the stone in this case from without, and this would have in all probability been insufficient to accomplish its disintegration; and, moreover, we have evidence in the rounded angles of most of the fragments that they must have lain in the bladder for a longer time than sixteen days, which was the time from the first introduction of the catheter to the patient's death. In view, therefore, of this fact, and of the forms of the fragments, which show, I think, conclusively, that the fragments originally belonged to one or more stones, we are justified in assuming that they represent the spontaneous rupture of stone in the bladder.

The only references to this subject which I have found in the writings upon stone are those of Boulouminé (*Union Med., Par.*, 1877, 3d S., xxiii., 25); William Ord (*Trans. Path. Soc., London*, 1876–1877, xxviii., 170); Von Thaden (*Arch. für Klin. Chir., Berlin*, 1865, vi., 202).

The first narrates the case of the spontaneous frac-

[1] Reported at the Society for Medical Improvement, Boston, November 22, 1886.

ture and passage of a number of fragments from a stone which had been recognized to be of considerable size by the sound, but as its disintegration was assisted by a lithotrite, the case is unsatisfactory.

William Ord showed the fragments of a stone passed spontaneously by a man of eighty-three years. The fragments were segments of a sphere or spheres, having a central cavity. The stones were of uric acid, coated with neutral urates. The author attributes the fracture to a sudden expansion of the central nucleus. No instruments had been used, and no force exerted from without.

Von Thaden describes the spontaneous passage of one hundred and eighty fragments of stone from a patient eighty years of age. They were of uric acid and the triple phosphates, and were chiefly in two forms: shells with concave and convex surfaces, and rounded segments, whose convexities approximately fitted into the concavities of the shells. No instruments had been used. The author also notices the following cases:

Specimen 1945, Walterischen Museum's; nine wedge-shaped bits removed from a patient of fifty years, which could be so adapted to each other as to form one symmetrical stone, weighing 3ij ℈ß.

Walther (*Med. Chir. Schatz Leipzig*, 1715), twelve fragments which had spontaneously fractured in the bladder, which could also be so placed together that, their surfaces fitting, made one stone. No force had been used to cause its fracture.

Crosse speaks of several cases, amongst which was one in which the stone was extracted whole, and subsequently fell in pieces.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

November 22d, 1886. The President, Dr. F. W. Draper, in the chair.

SPONTANEOUS FRACTURE OF STONE IN THE BLADDER.

Dr. F. S. Watson reported the case and showed specimens and a photograph.[1]

Dr. A. T. Cabot inquired if these were fragments of one or several stones.

Dr. Watson stated his impression that there were more than one, his reason being that the fragments were so much alike in size.

Dr. Cabot remarked upon the short radii of the different curved surfaces. He thought that small stones had been ground together.

Dr. E. S. Wood said that the color suggested urates or phosphates; but that chemical examination of some of these specimens of Dr. Watson's, which had been referred to him, showed them to be nearly pure uric acid. Uric-acid calculi are among the more friable ones.

Dr. J. B. Ayer reported

A CASE OF CHRONIC INTERSTITIAL NEPHRITIS.

Patient, fifty-one years old, colored, came to Boston at an early age. His father died of some urinary trouble, and his brother of chronic Bright's disease. He consulted Dr. Ayer for dizziness nine months ago, when the urine, examined merely as a matter of routine, was found to contain albumen, estimated at three-fourths of one per cent. Numerous specimens since examined have been estimated to contain from one-half to three-fourths of one per cent. Up to a month ago, when he gave up business, the average specific gravity of these specimens has been 1015, and the average amount of urine two or three pints. During the past month the specific gravity has averaged 1011 and the amount has steadily diminished. Three days before death, when little fluid was taken, the amount was ℥xxii.

When first seen, twenty-three grammes of urea were voided in twenty-four hours, somewhat less than two-thirds the normal amount, but this quantity was quickly diminished to eighteen grammes.

On the fifth, fourth and third days before death the average urea in the urine was eight grammes, less than one-quarter the normal.

As a rule no casts were found — the few which were seen were hyaline or granular.

Palpitation, although the heart was much enlarged, was not a troublesome symptom. On one occasion only was a mitral souffle detected. Nausea was quite constant, although vomiting rarely occurred. Milk diet at times was very repulsive. Subcutaneous œdema was absent. His prominent symptoms were increasing muscular weakness and mental worry.

While active there was only one occasion, at a concert, when he came near loss of consciousness.

When his mind was not occupied he was constantly directing his attention to himself, and by night he was sometimes bewildered, toward the end of his life, but while attending to his duties the mind was clear, and when not fatigued he did not seem ill. Œdema of the lungs and coma were present during the last forty-eight hours of life.

Dr. E. G. Cutler, who showed the specimens, said that the chief interest lay in the kidneys. They were estimated to weigh five, and four and a half ounces respectively. The capsules were quite adherent and numerous small cysts were found scattered over the uneven surface. The color was dark, mixed with yellow. On section the kidneys were dense, the cortex was ill-defined and its malpighian bodies and tubules not easily seen. The color was mottled yellowish red; there was great injection. A microscopic examination showed an increase of interstitial tissue, a thickening of the capsule in many of the malpighian bodies, certain capsules sclerosed, many tubules denuded of their epithelium and dilated and tortuous. Here and there casts, both granular and hyaline in the convoluted tubules — hyaline casts in the looped tubules, and a thickening of the arterial tunics. The capillaries were large and filled with blood.

The heart weighed over two pounds and was of good color and consistence, the enlargement being wholly in the left ventricle. There was no disease of the valves.

Dr. M. H. Richardson reported a case of

SPERMATORRHŒA.

The patient has ejaculations on the slightest provocation, the touch of a razor to the face being enough to cause one. He also complains of ejaculation during defecation. A specimen of the fluid lost during this

[1] For Dr. Watson's report see page 524.

act had been secured and was shown to the meeting. It proved to contain spermatozoa. Before seeing Dr. Richardson, cold sounds had been used for three years, and deep injections, both without effect. The patient asks to have the prostatic urethra cauterized, and Dr. Richardson is inclined to make use of this treatment.

DR. WATSON said that he thought that physicians underrated the frequency and importance of true spermatorrhœa, which was generally treated as existing chiefly in the imagination of the patient, the thick, gummy discharge, of which they complained as occurring at the end of urination or during defecation, not being examined microscopically. If this be done, a certain number of specimens will be found to contain spermatozoa, generally dead, owing to having been passed back into the bladder and lain for some time in the urine. The mental depression, and hypochondriasis associated with this condition as well as a train of symptoms too long to enumerate here, that are generally observed in this malady are very marked, and constitute its most difficult feature in treatment. The actual local condition, which consists in hyperæmia, and disturbed innervation, are generally greatly improved by large cold steel sounds, or the hollow sound rendered cold by a current of water, and deep injections of nitrate of silver, never stronger than five grains to the ounce, and preferably one or two grains to the ounce. Dr. Watson did not believe in cauterizing the prostatic urethra in these cases, a practice originating with Lallemand, and thought that it might eventuate in stricture.

DR. ARTHUR T. CABOT read a paper entitled

NOTES ON THE TREATMENT OF STONE IN THE BLADDER, WITH CASES.[2]

DR. WATSON said that he thought none of us, whether we have made a special study of stone in the bladder, or only viewed it with the interest attaching to any of the great chapters of surgery, can fail to be much interested in, and to learn something from Dr. Cabot's paper. He is, moreover, to be congratulated upon the results of treatment in this series of cases.

As the author of the communication has pointed out, the question of the treatment of stone has of late become focused upon two operative procedures (with the exception of the cases occurring in children) the litholapaxy of Professor Bigelow, and the high cut above the symphysis pubis, as improved by Petersen. In regard to the former nothing need be added to what Dr. Cabot has said in his paper. With respect to the latter, we cannot yet say if other improvements may not place it on an equal footing with its brilliant and already successful competitor. One of these would be the discovery of some way of so entering the bladder wound as to secure a union by first intention, which would materially shorten the course of convalescence, and abate the dangers arising from the presence of urine in the wound. There have already been several successful results of bladder suture, but they are not yet sufficient in number, to warrant the hope that primary union will be the rule. It must be remembered, in comparing the statistics of litholapaxy with those of the high cut, that until recently only cases which were deemed unsuited to or impossible by the former operation, were reserved for the latter. Nevertheless the disparity between the mortality of twenty per cent. in the supra-pubic operation and three per cent. in litholapaxy, is too great to be wholly accounted for on this ground, and until the numbers shall become more equalized, we do not need to be accused of local prejudice in giving preference to litholapaxy when it can be done.

The speaker was glad that Dr. Cabot had pointed out the importance of the habitual and systematic use of the catheter in the after-treatment of stone which occurs in connection with hypertrophied prostate, a fact not much dwelt upon in writings on the subject. The residual urine behind the dam made by the prostate in such cases, forms a pond in which sediment very readily forms, and may lead to the early recurrence of stone.

There is also one point in regard to the formation of phosphatic stone, of which the author did not speak, and which, though not of frequent occurrence, has some importance. He referred to those cases in which the phosphatic formation is not due primarily to decomposition and alkalinity of the urine in the bladder, but to the condition known as phosphaturia, in which the urine, as it is excreted by the kidney, is already neutral or alkaline, and the amorphous phosphates are precipitated sometimes before they reach the bladder.

In this condition the phosphates are either found in excess, or as is more generally the case, are precipitated by the absence of a sufficient quantity of acid phosphate of sodium to hold them in solution. Clinically, the condition is easily recognized by the fact that the amorphous phosphates appear at the end of urination as a distinct milky-white discharge, often passed with some pain and vesical tenesmus, and by the fact that the alkalinity of the urine is due, not to a volatile ammonia, but to a fixed alkali. The last distinction can be easily made by heating the urine in a test-tube, having previously stretched a bit of test paper across its mouth. If the alkalinity be due to ammonia, the paper will show the characteristic reaction, if to a fixed alkali, it will not. Recognition of this condition is important, with respect to treatment. In phosphaturia, one would not expect to remove the cause of the trouble by local treatment of the bladder, but should direct his efforts to overcoming the alkalinity of the urine in the kidney. This may be accomplished in some cases by supplying the wanting acid, in giving dilute phosphoric acid, from ten to fifteen drops thrice daily, in a half-glass of soda water.

In conclusion, Dr. Watson wished to say a word about the use of cocaine in stone operations. Where, for any reason, it is undesirable to give ether, this drug may be employed with advantage, and a litholapaxy be performed, which could not otherwise have been done without encountering the risks of etherization on the one hand, or inflicting great pain on the other. He had operated upon one patient in this way about a year ago, with entire absence of pain, the operation lasting half an hour. It is quite safe to use a ten per cent. solution in the bladder, owing to the fact that absorption does not go on readily from its coats, and an ounce or two may be introduced into an empty bladder, and repeated if the operation be prolonged.

DR. J. W. ELLIOT said that stone in the female bladder is commonly formed upon the stitches put in for the cure of a vesico-vaginal fistula, or upon foreign bodies introduced by hysterical patients. Treatment is by dilating the urethra, crushing, and drawing out

[2] See page 518.

the pieces; by cutting into the base of the bladder through the vagina; or by litholapaxy.

Drawing the crushed stone through the dilated urethra, formerly the common operation, sometimes causes great laceration. Opening the base of the bladder is a simple operation and has been done many times with success. Litholapaxy, done with the modification of Dr. Cabot, may often be the better way. Dr. Cabot had in conversation, suggested to him what he had to-night shown upon the blackboard, and he had made practical use of the suggestion in an operation. With the patient unetherized, he could not elevate the handle of the lithotrite enough without causing pain, and he could not crush the stone. But on etherizing and then holding the handle vertically, as Dr. Cabot had proposed, the stone fell into the instrument; and this happened every time that it was tried.

Dr. H. L. Burrell said that he had been very much interested in Dr. Cabot's admirable paper. His own experience in litholapaxy had been limited to four cases, but had been rather an eventful one. The first case had rather a protracted convalescence, the second recovered promptly. The third case was that of a feeble man, aged seventy-six, who for a number of years had been living a "catheter life" owing to an enlarged prostate. Had at times hermaturia with pain in the end of the penis, urine clear and cloudy by turns, at one examination albumen and granular casts were found. A stone was found, and under ether a No. 2 lithotrite was introduced and the stone was crushed. Two hundred and twenty grains of detritus were evacuated; the lithotrite was again introduced and more fragments of stone were crushed; on reintroducing the evacuating tube (straight), a slight obstruction was felt, it was withdrawn, and several attempts were made to repass the tube into the bladder; this was thought to have been accomplished when the evacuator was attached, but it was found that the rubber bulb would not expand. An explanation was sought, and on introducing the finger into the rectum the tube was found resting in the tissues between the bladder and rectum. A rupture of the urethra had occurred. The evacuating tube could not be passed into the bladder, hence a median perineal cystotomy was performed, much difficulty being experienced in entering the bladder; the fragments which remained were partially evacuated and the patient was returned to bed. He never rallied from the shock and died some six hours later. In reviewing the case the operator remembered distinctly a slight grating hitch on removing the lithotrite the second time, and doubtless a sharp fragment of stone was drawn from the bladder into the membranous urethra, where it rested until the evacuating tube was reintroduced. This pressed the sharp fragment backward, tearing the floor of the urethra, and on again passing forward the evacuating tube, it engaged in this false passage. When the cystotomy was performed, a fragment of stone was found between the urethra and rectum which would support the above explanation. Dr. Burrell said that he spoke of the case to emphasize one of the dangers of litholapaxy, that of drawing fragments by the lithotrite or tube into the urethra, where they might do irreparable damage.

The fourth case that he had operated upon was remarkable for the size of the stone and the length of time consumed in removing it. The patient was a healthy farmer, aged thirty-five, from Nova Scotia, who had suffered from symptoms of stone for three years. He was an ideal patient to stand a prolonged operative procedure, being thin and very muscular. The stone was crushed with some difficulty, as the lithotrite kept getting clogged. The operation lasted five hours and a quarter and the quantity of calculous material was 3,360 grains before being dried, and 2,400 grains after drying. The convalescence was uninterrupted except that an abscess formed over the sacrum from the prolonged pressure on the operating table. Dr. Burrell thought that this was one of the largest stones that had ever been crushed and successfully removed. In three weeks the patient returned to his home, completely well.

Dr. Cabot said that the case was one of triumph for litholapaxy. Mr. Keagan has reported crushing a stone of 2,800 grains, a little larger than Dr. Burrells.

THIRD ANNUAL MEETING OF THE NEW YORK STATE MEDICAL ASSOCIATION,

NOVEMBER 16, 17, 18.

DISCUSSION ON SHOT-WOUNDS OF THE INTESTINES. NOVEMBER 16.

The discussion was opened by a paper by Dr. Wm. S. Tremaine, of Buffalo, in which he quoted from various standard surgical works, and then remarked that but a faint light was thrown on the subject by the highest authorities. Among the circumstances which were to be taken into consideration in dealing with abdominal gun-shot wounds, were the calibre of the ball, the proximity of the weapon, and the direction of the entrance and exit of the missile. Among the symptoms of perforation of the intestines were prolonged shock, tympanites, severe pain, anxiety, and restlessness. Escape of blood from the anus, which the late Professor Gross regarded as of special significance, rarely occurred, but, when present, was of much diagnostic value.

He recommended laparotomy in wounds of the abdomen for the purpose of diagnosis, first, because the intestines might be injured; second, because, in nine cases out of ten, it was required for the removal of effused blood, which it was dangerous to allow to remain; third, because the abdominal section added but a very slight element of danger; and fourth, because by this means assurance could be given to the patient in many cases that the intestines were not wounded. Where there was positive evidence that the intestines were implicated, there was no question of the propriety of laparotomy.

The operation had been successfully performed in America in three cases in which there was intestinal perforation, two of them belonging to Dr. W. T. Bull, of New York, and the other to Dr. John B. Hamilton, of Washington. As to the time when laparotomy should be done, he thought it should be undertaken as soon as possible after the receipt of the injury, first, because the immediate shock paralyzed peristaltic action, and thus tended to prevent extravasation of fæces for a time; and, second, because delay increased the dangers of peritonitis. In consequence of the desirability of early operative interference, he advised, therefore, that physicians throughout the country

should familiarize themselves with the procedure by practising upon animals, so that they would be prepared to operate in cases of emergency.

In speaking of the technique, Dr. Tremaine particularly recommended the suture of Lembert, which was also advocated by the speakers who followed him. When the operation was completed, it was essential that a clean cavity should be left.

The first question,

WHAT ARE THE DIAGNOSTIC SIGNS OF THE INVOLVEMENT OF THE INTESTINES IN SHOT-WOUNDS OF THE ABDOMEN?

was discussed by DR. JOSEPH D. BRYANT, of New York. He said that there were two classes of symptoms: one referable to the abdomen itself, and one to the constitutional effects of the injury. In studying the local evidences of trouble, the surgeon would investigate the wound of the abdominal wall, the direction of the missile, the character of the discharges, and the presence or absence of emphysema of the borders of the wound, or in the neighboring connective tissue. If the direction of the ball indicated that the peritoneal cavity was penetrated, the presumption was that the intestines were wounded. Still, there were cases on record in which the cavity had been penetrated, and yet the intestines remained uninjured.

If the bleeding points in the abdominal wall would not account for the amount of hæmorrhage present in any case, it was altogether likely that the intestines were perforated. The same was true if there was bloody urine. Of course, the escape of the intestinal contents was proof positive of perforation, but this was rarely met with soon after the injury. Emphysema was not very frequently seen, but when present, it was almost invariably due to the escape of gas from the intestines. Early emphysema of the abdominal wall had been regarded as a positive sign of intestinal perforation, but while this is true, as a general rule, he had personally met with two instances in which the emphysema was caused by the suction of the abdominal muscles. If decomposition were present, emphysema might also occur without rupture of the intestines, but this was apt to be met with only quite late.

Having referred to pain, tympanites, bloody stools, and retention as significant signs, he went on to speak of hepatic resonance. While this was almost pathognomonic, it was to be borne in mind that it might possibly be due to other causes. Thus, it might result from the transverse colon getting between the liver and the abdominal wall, or from the tilting of the liver out of its normal position. There might be shock and nausea and vomiting, hiccough usually following the latter. If there was severe shock from the first, it usually indicated intestinal perforation and hæmorrhage. Extreme thirst, restlessness, anxiety, and subnormal rectal temperature were all corroborative signs of perforation. There were, indeed, but very few positive early indications of the condition, but loss of hepatic dulness, unless previously modified by change of position, or abnormal processes in the liver, was undoubtedly one of the most valuable.

WHAT SHOULD BE THE FIRST MEASURES OF TREATMENT IN SHOT-WOUNDS OF THE ABDOMEN INVOLVING THE INTESTINES?

was to have been discussed by DR. E. M. MOORE, JR., but he was not able to be present. It was taken up, however, by some of the other speakers.

DR. W. T. BULL, of New York, spoke on the third question,

UNDER WHAT CIRCUMSTANCES, AND HOW SOON AFTER THE INJURY SHOULD LAPAROTOMY BE RESORTED TO IN CASES OF SHOT-WOUNDS OF THE INTESTINES, AND WHEN IS THE OPERATION CONTRA-INDICATED?

He said that laparotomy was in general indicated, in the first place, for diagnosis. Many cases presented but few of the characteristic symptoms of perforation. Again, a bullet which had entered the peritoneal cavity was much more apt to have injured the gut than not. As to the time when laparotomy should be performed, he thought it should be done as soon as the immediate shock of the injury and of the removal of the patient were past. Delay only invited the onset of septicæmia, and he did not think it advisable to wait for the appearance of symptoms. Exploratory laparotomy was not without good effect even in non-penetrating wounds.

Since the year 1877 he had seen eight cases of penetrating shot-wounds of the abdomen, at the Chambers Street Hospital, New York. Five of these were treated on the expectant plan, and all proved fatal. In the other three cases laparotomy was resorted to, with the result of two recoveries and one death. In the first of the successful ones which had been reported in full in 1884, seven wounds of the intestines were sutured. The second occurred in August, 1886, and had recently been reported by Dr. Bull, at a meeting of the New York Surgical Society. The patient was twenty-five years of age, and the operation was performed two hours after the receipt of the injury. Three wounds of the intestines were sutured, and two wounds of the mesocolon were not sutured but rubbed thoroughly with iodoform. One of the appendices epiploicæ, of good size, which was found torn and bleeding at its extremity, was tied at its base with catgut and cut off. The external wound did not heal entirely for eight weeks, as there was sloughing of the peritoneum along the line of sutures, and protrusion of a portion of intestine which firmly adhered to the parieties. The edges of the wound were held together with two "relaxation sutures" of silver wire, and compression was made on the intestine with a small pad of iodoform gauze and wool. By means of these the gut was pushed back from day to day, while the edges were being drawn together and the lower part of the wound was filling with granulations. The man was now perfectly well and pursuing his usual avocations.

The third and unsuccessful case was operated on November 6, 1886, and had not as yet been reported. The wound was made by a forty-four calibre ball. The incision was made in the median line, and four perforations of the intestines were sutured. The operation lasted one and three-quarters hours, and death, which was probably due to the shock from the laparotomy, occurred eight hours afterward.

Dr. Bull explained that none of these three cases presented any positive proof of perforation of the intestines before the abdomen was opened. Yet the lesions found in the last one, as well as in the others, indicated operative interference. Having briefly referred to the five fatal cases treated on the expectant

plan, he went on to speak of the contra-indications for laparotomy. It was to be borne in mind, he said, that in many instances the solid organs, such as the liver, spleen, and kidneys — though the latter did not present so serious a complication as the others — were wounded as well as the intestines; and he doubted the ability of the surgeon to cope successfully with such cases. Uncomplicated wounds of the intestines were not, in his experience, accompanied by profound shock; and profound shock was, therefore, a decided contra-indication. The exposure and handling of the viscera were not devoid of danger. Peritonitis was not in his opinion necessarily a contra-indication.

As to what should be the first measures of treatment, he advised that the bullet wound should first of all be explored; except in cases where it was situated posteriorly, with no wound in front. In general, the two rules which he would offer for guidance were: (1) Assure yourself by exploration that the abdominal cavity has been entered. (2) Proceed to repair the injury.

Dr. Theodore R. Varich, of Jersey City, said that when there were present shock with gradually increasing exhaustion, sinking temperature, dulness on percussion of the dependent parts of the abdomen, and tympanites of the anterior portions, immediate laparotomy was demanded. The day of expectancy was past, and he thought that the surgeon should give his patient the chance offered by operation, however small it might be, as against the otherwise certain prospect of death.

Dr. Charles B. Nancrede, of Philadelphia, said that laparotomy should always be performed except when certain contra-indications were present. Among the indications referred to were the vomiting of blood or passage of blood per anum, the rapid accumulation of fluids in the abdomen, etc. As to the time for the operation, he thought it should be done just as soon as the patient's condition would warrant the performance of a long operation attended with shock, and the proper assistants and surroundings could be secured. When much hæmorrhage was probably taking place, however, it should be done earlier than otherwise.

Among the contra-indications were profound shock, unless this was due to hæmorrhage. He thought that by no means every physician was competent to perform laparotomy, and that as a rule, cases would do better if left to nature than if operated on by an incompetent surgeon. Experience was a prerequisite in this procedure; and, if possible, only one pair of hands should be allowed to enter the abdominal cavity. Acute peritonitis or wounds of other organs besides the intestines he thought might prove contra-indications.

The fourth question,

WHAT ARE THE ESSENTIAL FEATURES OF THE TECHNIQUE OF LAPAROTOMY, INCLUDING THE MANAGEMENT OF THE WOUNDED INTESTINE?

was discussed by Dr. John B. Hamilton, of Washington. By way of preliminary he said that he thought the first thing to do in small pistol wounds was to use the probe; the instrument which he preferred being the flexible spiral probe of Nelaton. If the cavity of the abdomen was found to be penetrated laparotomy was indicated. Even if there were great shock exploratory laparotomy was indicated, as this was probably due to the wounding of a vessel, nerve or ganglion.

As to the technique of laparotomy in cases of this kind it did not differ from that of ordinary laparotomy, except as regards the treatment of the intestines. Strict antiseptic precautions should be employed, and towels wrung out of hot water should be laid on the abdomen. On opening the cavity a careful inspection should be made for bleeding vessels; and no abrasion should be left untouched. The intestines should be drawn up loop by loop by the fingers, and allowed to remain, a towel wrung out with hot bichloride solution; another towel being placed over them. It was necessary to reduce pouting mucous membrane. He used the Lambert suture, and preferred catgut for the purpose. The incision, he said in conclusion, should be closed as in other cases of laparotomy, after the cavity had been thoroughly cleansed.

The fifth question,

WHAT ARE THE BEST METHODS OF AFTER-TREATMENT IN CASES OF SHOT-WOUNDS REQUIRING LAPAROTOMY AND SUTURE OF THE INTESTINES?

was discussed by Dr. Nancrede.

Dr. Charles T. Parkes went rapidly over all the various points of the discussion. He said that if the abdominal cavity was penetrated, it might be considered certain that the intestines were perforated, and the surgeon should be deterred only on the strongest grounds from operating. Deep-seated emphysematous crackling he considers a valuable sign of perforation, when present. In discussing the second question he said that the first thing to do was to ascertain whether the wound entered the abdominal cavity; and he spoke particularly of the dangers associated with removal of the patient. As to the third question, under what circumstances laparotomy should be performed, he said, under all circumstances, unless the patient seemed likely to die during the operation. Complications of other organs were also contra-indications. As to the time for the operation, it should be performed just as soon as the surgeon's preparations could be made for it.

In the methods of procedure, he said, we should be guided by the same rules as in all grave surgical injuries. If perforation was present, there was no contra-indication to operating; and it was impossible to say whether a case was likely to be a fatal one or not until after exploratory laparotomy had been performed. In speaking of the technique of the operation he said that the median line was the only one for incision, and that he considered this a very important point. The first incision should be free, and the cavity having been opened, all bleeding vessels should be secured. Then all the small incisions should be drawn up through the incision, and wrapped in warm towels. Wounds in the large intestines and other viscera should be looked for. The whole of the small intestines should be passed through the fingers and carefully examined. In speaking of the treatment of intestinal perforations, he said that he thought Lembert's suture the best, and that a double row of sutures was entirely unnecessary. He employed a small round needle either straight or curved, and the material which he used for sutures was pure silk. Total resection of the gut was sometimes necessary. Finally, the abdomen should be closed in the ordinary way; care being always taken to avoid ventral hernia.

In the after-treatment, Dr. Parkes said, it was necessary that the patient should have complete rest.

Opium was required in sufficient quantities to secure this; and rectal alimentation was sometimes of service. If the temperature ran high, cold external applications were to be used; but if it did not rise above 101°, there was no necessity for interference.

OFFICERS ELECTED.

President, Dr. Isaac E. Taylor, of New York. *Vice-Presidents*, 1st District, Dr. Dodge, of Rouse's Point; 2d District, Dr. Sherer, of Waterford; 3d District, Dr. G. W. Avery, of Norwich; 4th District, Dr. Colvin, of Clyde. *Secretary*, Dr. E. D. Ferguson, of Troy. *Treasurer*, Dr. J. H. Hustin, of New York. *Director of the Library*, Dr. J. W. S. Gouley, of New York.

Time of meeting next year, Second Tuesday in October.

Recent Literature.

Insanity and its Treatment, Lectures on the Treatment, Medical and Legal, of Insane Patients. By G. FIELDING BLANDFORD, M.D., Oxon, etc. Third edition. Together with "Types of Insanity," an Illustrated Guide in the Physical Diagnosis of Mental Disease, by Allan McLean Hamilton, M.D. pp. 379. New York: William Wood & Co. 1886.

These productions together form a volume of Wood's Library of Standard Medical Authors. The third edition of Blandford's lectures, of which the bulk of the book is composed, diminishes in no essential respect its prestige as a practical manual for instruction. Its merits are simplicity of method, clearness of expression, brevity and compactness of matter and an even treatment of the various parts. The amount of space devoted to each subject is subordinated to its importance and value in practice, no impartiality being shown in this respect to any favorite line of inquiry. The classification followed is sufficiently accurate, and especially useful for purposes of instruction. Considering the purpose of the book there is little fault to be found with its completeness and scientific accuracy if we except the author's failure to accord any notice to paranoia or any of the recently established forms of primary insanity. Exception will also be taken by some to the writer's views as to "moral insanity" although they still have strong supporters. He also continues to hold chloral in high favor as a hypnotic in insanity, in spite of the decided and general belief to the contrary among alienists. Otherwise, the lectures are brought well up to date and may be said to remain in the van of English works on insanity designed for students and the general medical reader.

Hamilton's "Types of Insanity" a monograph of about fifty pages completes the volume. The presence of the illustrations is not easy to account for on the grounds of usefulness, and we must confess to an inability to rightly name by the likenesses several of the "types" represented in the plates. To us they illustrate only the futility of attempting to classify forms of insanity by the facial expression. The text, however, is a useful addition in a medico-legal way, a graphic description of the general appearance of an insane patient being not unfrequently the most effective part of expert evidence. A serviceable abstract of the laws of the various States on the commitment of the insane, also by Dr. Hamilton, is appended.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, DECEMBER 2, 1886.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

283 WASHINGTON STREET, BOSTON, MASS.

BRAIN SURGERY AGAIN.

NEARLY two years ago, we dwelt at considerable length in these columns [1] upon an operation for the removal of a tumor in the motor cortex of the brain, performed by Mr. Godlee, of London. As our readers may remember, the patient was in a fair way to recover when he succumbed to a secondary meningitis. Although a failure, the promise of that and other more successful operations incited other surgeons to similar operations with greater precautions and with better results, so that now brain surgery seems likely to become as well recognized a branch of the surgeon's art, within its limitations, as abdominal surgery. The existence of brain surgery, however, necessarily had to be secondary to the study of the localization of cerebral disease. It is needless now to say that, with the exception of the centres for speech, there is no fact in cerebral localization more firmly established than the existence of the various motor centres in the cortex of the central convolutions of the brain. The experiments of Ferrier, Fritsch, Hitzig, and others upon animals, in the sixteen years since they were first published, have been confirmed in regard to man by scores of autopsies.

Since the many experiments on animals have shown that the cranial cavity can be opened without fatal results, the old operation of trephining for epilepsy, which had fallen into abeyance, has been revived. Dr. C. F. MacDonald reports [2] two cases of trephining for traumatic epilepsy, in both of which there was a depression of the skull; these recovered, and some months later there had been no return of the fits. The mental impairment had become quite marked, and, although there was a gain in self-control, the dementia, of course, was not cured. As both these patients were criminals, the cases are suggestive to those who believe that crime is but one manifestation of mental disease.

Others, however, have trephined in cases of cere-

[1] Vol. CXII., 41, 67.
[2] "Report of Two Successful Cases of Trephining for Traumatic Epilepsy." Journal of Nervous and Mental Disease, August, 1886.

bral disease without visible depression, or even injury, being guided by the results of the topical diagnosis of the lesion. Mr. W. B. Mackay reports two cases of this sort:[3] one of right hemiplegia and aphasia from suppurating periostitis, where he trephined and found pus, but in this the patient died; the other a case of paralysis of the right leg, with exaggerated patellar reflex, due to a blow on the skull. In this case the patient recovered, and had good use of the leg. The most brilliant results, however, are those reported to the British Medical Association this summer by Mr. Victor Horsley.[4] In four cases of monoplegia, with epileptiform attacks beginning in the paralyzed limb, where the trouble was due to a tumor, or to some old cicatrix involving the meninges and the cortex of the brain, he has localized the seat of the trouble, trephined over it, cut out the cicatrix or tumor, with the portion of healthy cortex surrounding it: in every case the patient has recovered, and, although still paralytic, has remained free from the attacks. Furthermore, he suggests the propriety of excising the epileptogenous focus in cases of idiopathic epilepsy, where the discharge begins in some definite centre. We must refer to Mr. Horsley's paper for the details of his method of operation; we know not whether to admire most his exactness in localization or his skill in operation.

Considering the experimental data upon which cerebral localization is based, and noting Mr. Horsley's assertion: "I am one of those who do not consider it justifiable to try an experiment on man before I have found it to be harmless in the lower animals," and also his statement as to the information such experiments gave him in judging as to healthy and diseased parts of the living brain, it would seem as if the anti-vivisectionists ought to be convinced that experiments on living animals did some good. We will venture to say that Mr. Horsley's patients believe so. There is no process of reasoning, however, that could convince the poor woman who was peddling her tracts the other day about our streets, that our houses are not honeycombed, and our best citizens are not poisoned by the agents of the Czar of Russia; and all the results obtained from vivisection, from the days of Democritus, of Abdera, to the days of Mr. Horsley's operation, would fail to convince a class of self-styled philanthropists of which the editor of the *London Spectator* and Miss Frances Power Cobbe are types, that the slightest benefit could ever accrue to humanity from experimentation on living animals.

ARE ALL VENEREAL PATIENTS LIARS?

Physicians who like to be epigrammatic even at the expense of exact truth sometimes say that one of the first symptoms of syphilis is an unusual readiness in lying, and it seems to be a very wide-spread belief that it is impossible for a patient afflicted with venereal disease to tell the truth.

Whenever any difficulty arises in reconciling the statement of the patient with the physician's theory of the lesions presented, it is very easy to settle the matter by saying that venereal patients are never to be believed.

It is very certain that very great temptations to deceive are sometimes presented to this class of patients and that some of them go to absurd lengths of mendacity in their desire to conceal the cause of their troubles, but the question arises whether physicians do not carry their unbelief to an extent even more absurd. In our desire to escape imposition do we not refuse credence to patients who would be granted ready belief in other matters? Do we not require of venereal patients more accurate pathology and more careful observation than of others? In weighing the words of the patient do we give full force to the many things which may deceive the doctor?

One cannot rashly accuse of intentional dishonesty the man who so incriminates himself that he has no motive left for concealment, nor the man whose word the doctor is in the habit of accepting in the business affairs of life, nor the doctor who comes as a patient to consult as to his own case which he cannot understand. Anomalies constantly occur which do not conform with our preconceived ideas, consequently we too easily believe the patient's story to be untrue.

It is not without interest and instruction to notice some of the things that tend to make a diagnosis without the history difficult if not impossible. The initial lesion of syphilis may be counterfeited in many ways: Among other ways, a recurring induration may show itself months afterwards at the site it originally occupied, but from which it had disappeared. An ulcerating gumma may approach the initial sore most closely in appearance. Cornil mentions a series of mucous patches, existing simultaneously with a secondary eruption, which had an indurated base so that it was impossible to recognize them from primary sores without reference to the concomitant lesions on other parts of the body. Any of these appearances seen for the first time might puzzle the physician in his attempt to properly connect the lesion and the history.

Various non-syphilitic lesions may be referred by the physicians to a contagion which the patient denies. Mauriac describes an idiopathic induration of the glans, and also what he terms anthracoïde of the glans, either of which might suggest a primary sore. Greenough gives the history of an herpetic ulceration that from its position at the edge of the prepuce became inflamed and indurated in such a fashion that a specialist if he had seen it without knowing the history would certainly have called it an initial lesion of syphilis.

The inability of patients to tell when they had syphilis, or whether they ever had it at all, is taken as an evidence of the total depravity which attends the disease. The ease with which the disease may remain undiscovered by the bearer of it is hardly credible

[3] "Trephining over the Motor Areas of the Brain." Edinburgh Medical Journal, July, 1886.
[4] "Brain Surgery." British Medical Journal, October 9, 1886.

until one has had experience with it. Its peculiarity of painlessness in its early manifestations, outside of the neuralgic pains which are often wanting, renders it a not infrequent occurrence that the eruptions are first discovered by the doctor when consulted for some other trouble. Such patients are perfectly frank in remembering a gonorrhœa simply because it is more painful, requires more care to avoid exposure, and really occasions more discomfort. It is not infrequent that a gonorrhœa masks the symptoms of an accompanying syphilis, for the patient refers the slight sore and the glands in the groin to the already existing urethritis, and he is always positive in his assertions that he has never had syphilis, and it is very true that he has never had anything that he has known as syphilis.

The many non-venereal ways in which syphilis may be communicated and the frequency of such an occurrence account for many of the irregular histories with which patients regale us. There is another possibility to be considered also in some of the anomalous cases in which patients deny antecedents; late hereditary syphilis is assuming an importance never dreamed of until quite recently, and it is by no means impossible that heredity may account for late symptoms in some of the cases of unexplained origin.

Some of the most apparently shocking departures from the truth are committed in reference to gonorrhœa. The ease with which an urethra damaged by a previous inflammation will again take on inflammation is not always appreciated; the non-specific inflammations of the urethra we know little about, and the same is true of the cases of mediate contagion. Otis has established the fact so far as human testimony can establish it that the oft ridiculed infection from a water-closet may occur. One case occurred in the person of a physician who voluntarily went to Otis to narrate the fact. Of course the inference must always be against the claim of such an occurrence but its possibility cannot be denied.

The object of these remarks is by no means to induce physicians to give credence to every absurd story that is told them but rather to influence them to look upon the stories of venereal patients with the same judicial consideration with which they would regard the histories of other patients: not to favor indiscriminate credulity but to counteract a tendency to indiscriminate incredulity.

MIND-READING AND MUSCLE-READING.

DURING the past week the public has been treated to numerous accounts of how "his Imperial Majesty, Alexander the Third, Czar of all the Russias," has been astonished at the marvellous power of mind-reading possessed by Mr. Washington Irving Bishop, who is now with us. From a circular, we learn that nearly all the crowned heads of Europe have likewise succumbed and have become earnest believers, and now the lesser American lights are to be treated to an exhibition of the marvellous. As preliminary to Mr. Bishop's great public exhibition and his "farewell reception *extraordinaire*," a private performance was given at a hotel last week, to which a number of people were invited.

In thinking of this preliminary entertainment, one knows not at first whether to laugh or to be angry — to laugh at the credulity of human nature in general, and the facile manner in which even the most skeptical are manipulated and exhibited, in spite of themselves, as advertisements for Mr. Bishop and his subsequent exhibition, or to become angry at the masterly impudence of the performer in palming off an exhibition of so shallow a character as one of true mind-reading. There certainly is a humorous side to the matter, which even the most disappointed can enjoy. It is fortunate for Mr. Bishop that he comes at a time when "thought transference" has become the subject of true scientific investigation, and as such, is occupying the attention of those interested in that class of subjects. In consequence of this, he has found a number, who, from real scientific interest, were ready to meet him and witness his experiments, in the hope that he might have something which would throw some light on this question. That this last might be the case many were led to believe from the public statements, assertions, and boasts which Mr. Bishop, with considerable adroitness, has caused to be distributed through the daily press and by circulars.

We were led to believe, for example, that in the final and culminating experiment, the "mind-reader" would drive through the streets blindfolded, and attached only by a slack wire to the wrist of his conductor. Without any other assistance or communication, the public was led to believe that Mr. Bishop would find a hidden object. Judge then of the surprise of the audience at seeing the modern Jason, after getting into the carriage, deliberately place the hand of one of the committee on the back of his (Bishop's) head and take the hand of another in his own, and in this attitude slowly drive off. The further history of the wire is lost with that of the owl. Whether or not Mr. Bishop continued to remain blindfolded after leaving the Vendome, no one but Mr. Bishop himself knows. We can however, say, that during nearly the whole drive, he was in contact with one of his conductors, and after he entered the house where the article was hidden he held the hand of one with the persistence of a drowning man clutching a straw. It may not be superfluous to add, that before leaving the hotel, Mr. Bishop took the unnecessary and not-advertized precaution to localize the general situation of the house on a map, perhaps that he might not get lost in our new park; and further, Mr. Bishop did not follow the route which was in the mind of the committee, though it was the said mind he claimed to be reading. The other experiments were all performed in the same way. The advertised conditions under which they were performed were about equally fulfilled.

It is hardly worth while to discuss the fallacy of the experiments as tests of the power of thought-reading. To medical men they are obvious enough. If Mr. Bishop had performed a single experiment without being in contact with his subject, there might be some reason to suppose he possessed the power of mind-reading. Or even granting the necessity, for some unexplained reason, of touching the subject; if "mind-readers" when searching for hidden objects would hold the subject's hand but sit still, and give up the peripatetic habit of wandering round the room, or streets of the city, in such intimate company with the subject, something like evidence of mind-reading would be shown. Or if they would read the numbers of bank notes or anything else without a black-board or pencil and paper, or other such accessories, their experiments would be worth serious consideration. Under these conditions we could even forgive the clap-trap methods employed to impress audiences and the atmosphere of charlatanism with which they usually surround themselves. But, unfortunately, we fear that no one understands the childishness of these performances, so far as concerns thought-reading, better than the "mind-reader" himself. As exhibitions of the high degree to which muscle-reading can be developed, Mr. Bishop's performances are interesting. But we venture to say that muscle-reading is not as difficult as is generally taken for granted. We have reason to believe, that, with a little practice, nine persons out of ten could do most of the things performed by "mind-readers," even if not with the same facility as a professional with many years' practice. The Society for Psychical Research has invited Mr. Bishop to appear before it, and give genuine proofs of "mind-reading." It is understood that he has accepted. We trust that their waiting will not be a long and weary one.

MEDICAL NOTES.

— Dr. J. Solis Cohen has noticed a peculiar perversion of the temperature sense of the tongue and oral cavity, caused by strong solutions of cocaine. While still capable of appreciating heat, the patient cannot recognize cold, and iced water seems of blood heat, or even warmer.

BOSTON.

— The late Dr. Luther Parks, whose death was recently reported from Pau, France, was at one time editor of this JOURNAL. For the last twenty years he had resided abroad.

— The following circular was posted on the closed doors of many of the drug stores in Boston, Sunday, the 28th inst: To the Members of the Boston Druggists' Association — Gentlemen: At a meeting of the Boston Druggists' Association, held at the Revere House, Tuesday evening, November 23, a committee with full powers was appointed to take into consideration the recent action of the Boston Police Commissioners in closing drug stores on the Lord's day, and to make such recommendations as they thought best. In the performance of this duty, the Committee met at the Revere House on the 24th, and respectfully submits the following statement and recommendations:

In the first place, your Committee cannot see why the retail druggists should be among the first selected for the enforcement of the Sunday law. It is well known that the barbers were ordered to close their shops because a majority of them had petitioned for the enforcement of the law. It is hard to understand why the greatest law breakers are not noticed in this Sunday enforcement act, particularly those that have no claim whatever to works of necessity or charity, but do Sunday work simply because it can be done more cheaply. We refer more particularly to railroad companies, who lay tracks, build bridges, advertise excursions, run trains day and night; livery stable keepers, whose business is largely for pleasure; telegraph and telephone companies, who make repairs because they can be done more convenient than on week days; newspaper companies, who print, sell, and distribute their largest editions on Sunday; milk peddlers, and others.

We are well aware that it is no excuse for one violater of the law to quote another, but we have a right to expect that the strong arm of the Boston police would first grapple with the most flagrant violaters of the law, rather than with those that administer to the wants of the poor and sick. We can say with truth and sincerity that no class of men would be more delighted to close their places of business on Sunday, or shorten their hours of work on week days, than the druggists; and that there are no more law-abiding citizens, as the records of the courts will show. We believe it unwise on the part of the Police Commissioners to select the druggists of Boston on whom to enforce a law that has been obsolete for half a century, and especially when it was not attempted in any other part of the State.

If people will not call physicians on Sunday, and doctors will not visit or prescribe for their patients; if accidents will not happen; if children are not born; if people never forget to obtain their medicines on Saturday; if no one dies on the Sabbath; and if the poor will pay doctors to provide all the medicines they desire, then the Sunday law can be enforced to the letter (so far as relates to the drug trade).

The Police Commissioners are not the law-makers, and cannot grant any privileges, or define what kind of business may be carried on, or what goods may be sold, but must enforce the law in full, or not at all; therefore, there is no safety or propriety in doing any business on the Lord's day. If the wants of the public can be met within the six days' limit, as in other trades or professions, no one will be better pleased than the retail druggists. This is for the public to determine, and we must await their decision, which, in a matter of this importance, will not be long in coming.

In view of these facts, we recommend that druggists

close their stores, and do no business whatever on the Lord's day.

Per order of Committee,
BOSTON DRUGGISTS' ASSOCIATION.

NEW YORK.

— A new medical charity has been organized in the northeastern part of the city to be known as the Yorkville Dispensary and Hospital for Women and Children. A number of physicians living in the neighborhood are among its trustees, and articles of incorporation have been secured for it.

— The anniversary exercises of the Brooklyn Home for Consumptives were held in the church corner of Clinton and Pierrepont Streets, on the evening of November 22d, when Gen. A. C. Barnes presided, and the occasion was made as attractive as possible by addresses by the Rev. Henry Ward Beecher and ex-Mayor Seth Low, by vocal and instrumental music, and by an original poem written for the occasion by Will Carleton.

— The Thirty-Fourth Annual Meeting of the Children's Aid Society was held November 23d, when the President, Mr. William A. Booth, who has held the position for twenty-five years, was again re-elected. It was reported that for the Sick Children's Mission last winter $1,096 was spent. The Flower Mission distributed 115,000 bouquets, 3,000 cuttings, and 150 growing plants. The Summer Home, at Bath, Long Island, entertained during the season, 4,432 children. The Sanitarian at Coney Island, although much pressed for funds, took care of 1,048 infants and 635 mothers, and gave a day's entertainment to 2,648 additional mothers and children.

— The Association for the Advancement of Physical Culture held its second annual meeting at the Adelphi Academy, Brooklyn, November 26th. The President, Dr. Edward Hitchcock, read a paper on "The Need of Anthropometry in Physical Training," and a number of other papers were read and discussed. The German system of training teachers, now employed at the Milwaukee Normal School was also explained; after which there were exhibitions of gymnastics by a class from the Turnvereins of New York and Brooklyn, a class of ladies from the Brooklyn Normal School for Physical Training, and a class of boys from the Adelphi Academy. Dr. Hitchcock was again elected President.

— The first meeting of the Guild of St. Luke in this county was held at Calvary Church, November 19th. The charter has been received from the parent Guild, which was organized in England in 1864, and now maintains a hospital and efficient ambulance service in London. Its members are made up of clergymen of the Church of England, and students and practitioners who are communicants of the Church. The officers of the American Guild are, Provost, W. Thornton Parker, M.D., of Newport, R. I.; Vice-Provost, George H. Cleveland, M.D., of Pent Water, Mich.; Warden, Rev. George J. Magill, of Newport, R.I.; Treasurer, Rev. W. F. Morrison, Chaplain United States Navy. At the meeting of the Council, composed of these officers it was voted to appoint a medical missionary to be under the charge of the Bishop of Shanghai, China, and that the Provost should be empowered to appoint a corresponding secretary in every medical college in the United States. At the public meeting addresses were made by Bishop Quintard, of Tennessee, and the Provost, Dr. Parker.

— The Society of the Alumni of the University of Pennsylvania was organized at a subscription dinner given at Delmonico's, November 23d. Dr. Meredith Clymer presided, and the Provost of the University, Dr. William Pepper, Prof. Joseph Leidy, of the Medical Department, Prof. G. E. Bispham, of the Law Department, and Judge Henry Reid came on from Philadelphia expressly for the occasion. The speech of the evening was made by Dr. Pepper, who sketched the growth of the University for the past twenty-five years. Six new departments had been added, four within the last six years, and all are in active and successful operation. Twenty-five years ago there was barely 500 students, and of these 300 were in the Medical Department, which then had a non-graded course of two years' duration. At the present time there were 1,100 students, of which 400 were in the Medical Department. The standard of education had been greatly advanced in all the departments, and especially the medical, in which the examinations were made more rigid and the entire course more extended. The teaching force had been increased 25 to 146, and the literary productions of the institutions had increased in an even greater proportion. The last annual report gave a list of publications of the different Faculties, embracing 74 authors and 641 titles, including a considerable number of large and important works. The cramped accommodations of former days had been exchanged for spacious and elegant ones, and the buildings erected within the past fifteen years had cost upward of $1,000,000. The officers of the New York Society elected were, *President*, E. R. Robinson, Esq.; *Secretary*, Dr. E. C. Vidal; *Executive Committee*, Drs. Meredith Clymer, Alexander B. Mott and C. C. Lee, the Rev. Arthur Ritchie, and Col. Wm. McMichael.

Miscellany.

THE CAUSE OF CIRCULAR GASTRIC ULCER.

DR. SILBERMANN, of Breslau, has, we learn from the *Lancet*, lately made some experiments on dogs for the purpose of showing that the kind of anæmia characterized by deficiency of hæmoglobin in the red corpuscles of the blood is peculiarly favorable to the production and maintenance of circular ulcers of the stomach. Hæmoglobinæmia was produced by injection of various substances, and then either chromate of lead was introduced into a small gastric artery, or a ligature was applied to it, or the internal surface of the stomach was abraded by means of an œsophageal sound carrying a guarded point. All these animals

were found to have contracted gastric ulcers, and it appeared to make no difference whether the hæmoglobinæmia was produced before or after the stomach was injured. With the microscope it was found that a number of the red corpuscles were of a very pale color, and that the blood was less alkaline than normal, which is explained by the experiments of Preyer, A. Schmidt, and Rollet, who have shown that hæmoglobin is a weak acid. Dr. Silbermann considers that in the anæmia of hæmoglobinæmia all the conditions are present which are required by various theories for the production of gastric ulcer — namely, arterial anæmia (Klebs), venous hyperæmia of the gastric mucosa (Key), venous stasis in the hepatic vessels (Gunsberg), circumscribed hæmorrhages (Virchow), and, lastly, diminished alkalinity of the blood (Leube).

BLOWING UP THE COLON OR THE OPERATOR.

X ROADS, Nov. 29th, 1886.

MR. EDITOR,—I was much interested in the simple expedient recorded in your recent issue, for blowing up the colon with a tube in the mouth of the operator, the other extremity being inserted in the patient.

In reporting progress let me say that my teacher, Dr. Naso, having occasion to avail himself of this simple expedient at a farm-house ingeniously substituted for the rubber-tube a simple goosequill, the end of which was left protruding. He had no sooner adjusted himself at the orifice of this little tube than the patient sneezed, the result of which was, that instead of blowing up the colon, my teacher was most unexpectedly inflated by it.

It should be added, in justice to a great man, that he immediately recovered himself, and indignantly blew up the bystanders. But ought we not to be more careful?

Very respectfully yours, TYRO.

REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 20, 1886.

Deaths reported 2,276: under five years of age 881: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 475, consumption 353, lung diseases 277, diphtheria and croup 214, diarrhœal diseases 73, measles 68, typhoid fever 51, malarial fever 23, scarlet fever 22, whooping-cough 15, cerebro-spinal meningitis six, erysipelas three. From typhoid fever, Brooklyn 11, Philadelphia nine, New York and Baltimore eight each, Cincinnati four, District of Columbia three, Pittsburgh, Lowell, Cambridge, Lawrence, Haverhill, Malden, Fitchburg and Waltham one each. From malarial fevers, Brooklyn 13, New Orleans four, New York three, Philadelphia two, Baltimore one. From scarlet fever, New York six, Cincinnati four, Philadelphia and Pittsburgh three each, Brooklyn and Baltimore two each, Boston and Nashville one each. From whooping-cough Brooklyn six, New York three, Cincinnati two, Philadelphia, Baltimore, New Orleans and Charleston one each. From cerebro-spinal meningitis, New York five, Cincinnati one. From erysipelas, New York two, Pittsburgh one.

In the 21 cities and greater towns of Massachusetts, with a population of 959,810 (population of the State 1,941,465), the total death-rate for the week was 16.64 against 19.33 and 19.80 for the two preceding weeks.

For the week ending October 23d, in the Swiss towns, there were 21 deaths from consumption, diarrhœal diseases 18, lung diseases 13, whooping-cough six, typhoid fever four, diphtheria and croup two, erysipelas one.

The death-rates were: at Zurich 7.6; Geneva 15.1; Basle 11.8; Berne 20.3.

For the week ending November 6th, in the Swiss towns, there were 28 deaths from consumption, diarrhœal diseases 16, lung diseases 12, diphtheria and croup three, whooping-cough three, typhoid fever two.

The death-rates were at Zurich 19.1; Geneva 13.1; Basle 22.2; Berne 23.5.

The meteorological record for the week ending November 20, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps: —

Week ending Saturday, Nov. 20, 1886.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 20, 1886, TO NOVEMBER 26, 1886.

IRWIN, B. J. D., lieutenant colonel and assistant medical purveyor. Relieved from temporary duty in New York City, and of the charge of the medical purveying depot in that city and ordered to San Francisco, Cal., to take charge of the medical purveying depot in that city. S. O. 270, A. G. O., November 19, 1886.

TOWN, F. L., major and surgeon. Ordered from Fort Clark, Tex., to Post of San Antonio, Tex., to relieve Surgeon J. P. Wright. S. O. 159, Department of Texas, November 15, 1886.

GIBSON, JOS. R., major and surgeon. Ordered for duty as post surgeon, Fort Lyon, Col. S. O. 134, Department of Missouri, November 20, 1886.

POWELL, J. L., captain and assistant surgeon. Ordered for duty as post surgeon, Fort Supply, Ind. Ter. S. O. 134, Department of Missouri, November 20, 1886.

WALKER, FREEMAN V., first lieutenant and assistant surgeon. Assigned to duty at Fort McIntosh, Tex. S. O. 159, Department of Texas, November 15, 1886.

CLENDENIN, PAUL, first lieutenant and assistant surgeon. Recently appointed. Ordered to report to commanding general Department of Texas for assignment to duty. S. O. 271, A. G. O., November 20, 1886.

JOHNSON, HENRY, captain and medical storekeeper, will in addition to his present duties, assume charge of the medical purveying depot in New York City as acting assistant medical purveyor. S. O. 270, A. G. O., November 19, 1886.

APPOINTMENTS.

MOORE, JOHN, lieutenant colonel and assistant medical purveyor. To be surgeon general of the army, November 18, 1886.

BALL, ROBERT R. To be assistant surgeon with the rank of first lieutenant, November 19, 1886.

PROMOTIONS.

BAILY, JOSEPH C., major and surgeon. To be assistant medical purveyor with the rank of lieutenant colonel, November 18, 1886.

HEIZMANN, CHAS. L., captain and assistant surgeon. To be surgeon with the rank of major, November 18, 1886.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING NOVEMBER 27, 1886.

LAW, HOMER, L., surgeon. Ordered before the Retiring Board, December 2, 1886.

LIPPINCOTT, GEORGE C., passed assistant surgeon. Ordered before the Retiring Board, December 6th, 1886.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Boston Society for Medical Observation will be held at the Medical Library, 19 Boylston Place, on Monday evening, December 6, 1886. Readers: Dr. J. S. Greene, Dr. J. J. Putnam.

CHARLES P. STRONG, *Secretary*.

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The next meeting of the Society will be held at the Medical Library Room, No. 19 Boylston Place, on Thursday, December 9th, at 4 o'clock, P.M. Paper: Dr. E. W. Cushing, "The Use of Irrigation in Gynæcology."

H. J. HARRIMAN, *Secretary*.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT. — THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE will meet at 19 Boylston Place, on Wednesday, December 8th, at 7.45 o'clock. Dr. Morton Prince will open the meeting with some remarks upon mind-reading and muscle-reading. Dr. H. C. Haven will present a paper on "A Plea for a more Careful Consideration of the Importance of the Methods and Manner of Infant Feeding."

ALBERT N. BLODGETT, M.D., *Secretary*.
F. I. KNIGHT, M.D., *Chairman*.

GRADUATES OF DARTMOUTH MEDICAL SCHOOL.

The following gentlemen, graduates of the Medical Department of Dartmouth College, received their degrees, Tuesday, Nov. 23d:

Edward Shaffer Ballou, Rhode Island; Elmer Ellsworth Barrett, New Hampshire; Frederick Lucien Brigham, Vermont; John Cochrane, M.D., Massachusetts; Frank Edgar Colby, New Hampshire; Eugene Buchanan Dunbar, New Hampshire; Clark Henry Eldridge, B.S., Ohio; James Pringle Elliott, New York; Edward Clayton Frost, Maine; Fred Wells Granger, A.B., Massachusetts; Edward Bangs Hallett, Jr., Massachusetts; Adrian Hazen Hoyt, New Hampshire; Frank Taylor Lougee, New Hampshire; Alexander Daniel McKillop, Massachusetts; Cyrus Truman Meaker, D.D.S., Pennsylvania; William Henry Presby, New Hampshire; Joel Wilson Scudder, Vermont; Maurice Francis Sullivan, Massachusetts; Walter Kendall Wadleigh, New Hampshire. Total, 19.

DEATH.

Died at Plympton, Mass., November 28, 1886, Josiah Sturtevant Hammond, M.D., M.M.S.S., aged seventy-six years.

BOOKS AND PAMPHLETS RECEIVED.

Transactions of the American Otological Society, Nineteenth Annual Meeting. Pequot House, New London, Conn., July 20, 1886. Vol. III., Part 5. New Bedford, Mass., 1886.

Fifth Biennial Report of the Kansas State Insane Asylum at Topeka, for the Biennial Period ending June 30, 1886. Kansas Publishing House: T. D. Thacher, Topeka, Kansas, 1886.

Certain Hereditary and Psychical Phenomena in Inebriety. By T. D. Crothers, M.D., Superintendent of Walnut Lodge, Hartford, Conn. St. Louis, 1886. (Reprint.)

Address in State Medicine delivered at the Thirty-Seventh Annual Session of the American Medical Association in St. Louis, May 6, 1886. By John H. Rauch, M.D., of Illinois. (Reprint.)

Transactions of the American Dermatological Association at the Tenth Annual Meeting held at Indian Harbor Hotel, Greenwich, Conn., on the 25th, 26th, and 27th of August, 1886. Official Report of the Proceedings by the Secretary, G. H. Tilden, A.B., M.D. Boston, 1886.

Lectures

ON THE HYGIENIC LAWS AND SANITARY CONDITIONS OF ANCIENT ROME.[1]

(1) Introduction. (2) Drainage. (3) Aqueducts. (4) Roads. (5) Cemeteries. (6) Cultivation. (7) Centres of Population. (8) Results under the Empire. Physicians. (9) Middle Ages. (10) Modern Discoveries about Malaria. (11) Attempts to Improve. Eucalyptus, etc.

BY PROF. RODOLFO LANCIANI, LL.D.,
Government Director of Archæological Researches at Rome.

After describing in my last lecture the humble origin of Rome, and the simple matter-of-fact causes which led to its foundation on the Palatine Hill; after showing by the evidence of history how wisely the place had been selected from a political and commercial point of view, we must inquire this evening whether the selection was equally happy, as regards the sanitary conditions of the district which surrounded the new town. The argument is full of practical interest, on account of the mighty struggle which we modern Romans have actually entered into against malaria, against a plague which seems to be spreading slowly, but surely; everywhere there is a superabundance of moisture, both in the air and in the land; in other words, which is invading one-fifth, at least, of the inhabited world.

The history of malaria in connection with Rome must be divided into five periods: the pre-historic, the republican, the imperial, the mediæval, and the modern, each one marking a distinct stage in the increase or in the decline of the plague, as well as a change in the means adopted by the inhabitants of the fever-stricken district to protect themselves from the evil.

As regards the pre-historic period, we lack, of course, positive evidence, because, when ancient writers speak of hygienic matters at the time Rome was founded, either they speak at random, or else they saw things as they appeared in their own age. It seems probable that, at that time, all the low-lands surrounding the Alban volcanoes, as, for instance, the Pomptine, the Volscian, and the Latin districts, were comparatively healthy, on account of the purifying action of telluric fires, of sulphuric emanations, and of many kinds of healing mineral springs. In the deadly calm of nature which has succeeded the extinction of the Latin volcanoes, we find it difficult to conceive an idea of the endogenous activity which prevailed at that time. All along the valley of the Roman forum, which valley corresponds to a fissure or rent of the soil between the Palatine and the Quirinal hills, volcanic phenomena continued to appear, even in historical times. The chasm under the north-east spur of the Palatine, into which Marcus Curtius is said to have leaped, seems to have been the crater of a kind of geyser. Near the Janus quadrifrons there were hot sulphur springs, described by Varro (LLV., 32). In the fourth century before Christ, powerful jets of water sprang up suddenly in a street called Justeia or Justeiana. Julius Obsequens speaks of other jets of reddish water, near the Senate Hall, which he compares to blood (*sanguine fluxit*). The district of the Campus Martius is called *campus ignifer* by Livy, *fumans solum* by Valerius Maximus, τὸ πυρῶδες πεδίον by Zosimus, on account of volcanic smokes and emanations, which for centuries have been noticed there.

The Campagna must have been even more strongly purified, especially around the slopes of the Alban hills, where hot mineral springs were particularly abundant. At any rate, this is the only way to explain the presence of a thriving, healthy, strong, and very large population in places which, a few centuries later (namely, at the end of traditional, and at the beginning of historical times), are described as pestilential. Autunnæ, Collatia, Corioli, Tellene, Politorium, Crustumerium, and many other centres, so populous in volcanic ages, seem to have been obliterated more by the deleterious effects of the climate, than by the chances of war, and the overpowering supremacy of Rome. In the Volscian district, along the marshy Tyrrhenian coast, there were numberless settlements — Ficana, Lavinium, Ardea, Pyrgi, and so forth. As regards the Pomptine region, Pliny asserts that it was the abode of a dense and thriving population.

It may be a simple coincidence, it may depend upon a mere accident, this fact of the extinction of human life at the precise time in which volcanic life was extinguished in the old Latium, but it is a chance worth scientific investigation. There can no longer be any doubt that malaria invaded the volcanic regions the very minute they ceased to be volcanic.

As regards the site of Rome itself, we can hardly believe the words of Cicero (de Rep., 2, 6), by which he describes it as *in regione pestilenti salubris* — "salubrious in a pestilential region" — although the same observation is made by Livy, who considers it almost a prodigious fact that the town should prove healthy in spite of the pestilent and desert region by which it was surrounded (5, 54–7, 38). They evidently refer to the state of things prevailing in their own age. How is it possible that a hill like the Palatine, only a few feet high, and surrounded on three sides by poisonous marshes, should be exempt from the effects of malaria? The other hills of Rome were not better favored, hygienically speaking; the Cælian and the Aventine suffered from the effluvia of the swamps near the Porta Metronia, the Quirinal and the Pincian likewise from those of the Caprea Palus; in fact, Livy asserts that, before the construction of the Cloaca Maxima, every valley between the seven hills was nothing but a boggy quagmire. These hot-beds of malaria were fed by numberless springs, sometimes above, sometimes under ground, impregnating the whole region with dampness, which is one of the three, and perhaps the most active co-efficient of the plague.

The clearest proof of the virulence of malaria in the first century of the history of Rome is afforded by the large number of altars and shrines dedicated by its early inhabitants to the Goddess of the Fever and other congenial divinities. At the time of Varro, there were not less than three temples of the Fever left standing; one on the Palatine, one in the square of Marius, on the Esquiline, one on the upper end of the Vicus Longus, a street which corresponds to, within certain limits, the modern Via Nazionale. The Esquiline quarter seems to have been the worst of all as regards sanitary conditions; in fact, besides the Fever's temple, there was an altar dedicated to the Evil Eye (Mala Fortuna), and an altar and a small wood dedicated to the Goddess Mefitis. Near the Prætorian camp, and near the modern railway station, I have found, myself, an altar consecrated to

[1] The third Lecture of a Course delivered before the Lowell Institute, Boston, November, 1886.

Verminus, the God of Microbes. On the top of the Sacra Via, there was a shrine of Orbona, who is considered to be the Goddess of ———; and lastly, in the very centre of the Roman forum, there was an altar sacred to Cloacina, a goddess of typhoid, I suppose.

It appears from the particulars just given, that the primitive inhabitants of Rome, acting as men always do act under such circumstances, when they find themselves exposed to the ravages of an unknown evil, utterly ignorant of its mysterious nature, and of the proper way to fight and to lessen its effect, raised their hands towards their gods, and actually increased their number, and contrived new ones, imploring from Heaven the help which they failed to secure with their own resources. After a lapse of many, many years the request of those simple and energetic men was granted, and their town was made comparatively healthy, not in a supernatural or miraculous manner, but as a just and well-earned compensation for the efforts they had made and for the trouble they had taken to establish a better state of things. Strange to say, after the fall of the empire, when Rome, almost annihilated by the inroads of barbarians, found itself in condition almost worse than the condition of the early age, powerless to accomplish any work of improvement, and exposed again to the full influence of malaria, the inhabitants turned again their eyes towards God, built a chapel near the Vatican in honor of the Madonna della Febbre — our Lady of the Fever — which chapel became one of the most frequented and honored chapels of mediæval Rome.

The principal works of improvement successfully completed in ancient times for the benefit of public health, and for checking malaria may be chronologically described as follows: I. The construction of drains. II. The construction of aqueducts. III. The multiplication and the paving of roads. IV. The right organization of public cemeteries. V. The drainage and cultivation of the Campagna. VI. The organization of medical help.

First, as regards the drains: The plan of the Etruscan engineers employed by the second Tarquinius to organize the drainage of the town, seems to have been to give an outlet to the ponds and swamps and marshes which stretched along the valley between each couple of hills, more than to carry off the sewage in the modern sense of the word. The Cloaca Maxima, *receptaculum omnium purgamentorum urbis*, the main collector, as Livy describes it, has been praised, admired, eulogized by Dionysius 3, 67, Pliny (36, 15) Aurelius Victor (V. Ill. 8), Strabo (V. 3), Dion Cassius (49, 43), and in modern times by Niebuhr and Bunsen. There is no doubt that the work is simply wonderful, an immense sewer, built twenty-five centuries ago, on unstable ground, against enormous practical difficulties, which still answers well its purpose, and is a work to be classed among the greatest triumphs of engineering. But the exactness of an archæologist compels me to say that the Cloaca Maxima, in spite of its name, cannot any more boast of the priority which it has enjoyed for so many centuries in the department of Roman sewers. In walking along the left bank of the Tiber, I had long noticed the mouth of another cloaca a trifle larger than the Maxima, and separated from it by an interval of some three hundred feet. I had heard it called the cloaca of the Circus Maximus, but I was ignorant on whose authority and by what reason such name had been applied. Six years ago, at the bottom of the valley which separated the Palatine from the Cœlian, between the Arch of Constantine and the Church of S. Gregorio at Monte Celio, a cloaca even larger and higher than the Maxima was discovered, three-quarters of a mile from its junction with the Tiber, at the depth of forty feet. The enormous size of its blocks, the beauty and perfection of its masonry, and the wonderful preservation make it compare most advantageously with its rival, the Maxima, to which it is altogether superior as regards length and extent of district drained.

The sewers of ancient Rome answered pretty well their purpose, especially if we take into consideration the remote age in which they were constructed, and the ignorance of the engineers of modern sanitary principles, and of the theory of microbes. Their greatest defects are, first, that they were used at the same time to carry off the sewage and the refuse of the town, and the rain water; second, that this double employment made it necessary to have large openings along the streets, so that the population was permanently brought in contact with the poisonous effluvia of the sewers. Many of these mouths of drains have come down to us, some exceedingly rough and primitive, some more elaborate and cut in marble. The most celebrated, perhaps, is the so-called Bocca della Veritá, a marble disc, five feet in diameter, with the head of the Ocean in alto-rilievo in the centre, through the open mouth of which the rain water would escape. This monument, the scarecrow of children who show an inclination to lie, is preserved in the portico of the church of S. Maria in Cosmedin, near the ancient forum Boarium. The third defect of Roman sewage was that each sewer emptied directly into the Tiber, thus polluting its waters, which were not only used for bathing and swimming purposes, but which were actually drunk.

The best apology for this state of things is to be found in the fact that not only modern Rome itself but many other European capitals, not to speak of provincial towns and villages, were kept until lately in an absolutely identical condition. The improvement in the department of sewers is one of the last, if not the very last achievements of modern science, in connection with hygiene, and it is still far from perfection.

The introduction of pure drinkable water into Rome, took place not before the fifth century after its foundation. Sextus Julius Frontinus, a magistrate, who presided over the department of aqueducts, under the Empire of Trajan, begins his "Commentaries" on the subject with the following remarks: "During four hundred and forty-one years the Romans satisfied themselves with the use of such water as they could obtain on the spot, from the Tiber, from wells, or from springs. Some of these springs are still held in great consideration, on account of their supposed healing efficiency. Such are the springs of the Casuœue, of Apollo and of ."

The waters of the Tiber, reaching Rome after a run of 249 miles through clay or alluvial grounds, are certainly not pure or clear; in fact they are saturated with mineral and solid matter. It results from official observations carried on between March, 1871 and February, 1872, that with an average daily efflux of 1,296,000 cubic metres, the river has carried down to the sea, 8,582,333 tons of sand, equal to a volume of 4,114,253 cubic metres. In spite of this, what the

ancients assert about the potability of its waters is proved by the fact that, after the destruction of imperial aqueducts, the population of mediævial Rome resorted again to this the only means of quenching its thirst: in fact the desire and the necessity of being near the river, must be considered as the leading cause of the abandonment of the healthy hills, and of the mustering of the population in the Campus Martius. The salubrity of the waters of the Tiber is celebrated by Alessandro Petroni, physician to Gregory XIII, and by Alessandro Bacci, physician to Sixtus V. Clement VII, in the journey to Marseilles, which he undertook in 1553, to celebrate the marriage of his niece, Catherine de Medicis, with the Duke of Orleans, afterwards Henry II, acting on the advice of his physician Corti, brought with him such a quantity of water from the Tiber, as to be sufficient for all the requirements of the journey. The same precaution was taken by Paul III, Farnese, in his wanderings to Loretto, Bologna and Nice.

Fancy what must have been in early Roman times the sanitary conditions of a town, the drains of which, not washed by any influx of water, would communicate from space to space with the public streets by large unprotected openings, and would empty into a river, the polluted waters of which were drunk by the whole population! The first remedy against the evil was adopted in 442 by the building of an aqueduct, which should carry into the city the water of a spring seven and a half miles distant, called aqua Appia, from the name of Appius Claudius Cæcus, the builder of the aqueduct, and of the Appian Way. The first step in the right direction once taken, it was easy to advance boldly. I cannot follow stage by stage the history of Roman aqueducts. I will simply trace a brief and comprehensive sketch of the water-supply of Rome, under the Empire, that is to say, at the period in which it was brought to perfection.

Comparing together the accounts left by Frontinus and Procopius on this subject, with the remains of acqueducts radiating from Rome in every direction, and which form such a characteristic landmark of the Campagna, we gather the following information:

Eighteen springs had been collected and canalyzed by the Romans from distances varying from a minimum of seven and a half miles to a maximum of forty-four. The waters were brought to Rome by means of fourteen aqueducts, the length of which varies from a minimum of eleven miles, to a maximum of fifty-nine. The aggregate length of these fourteen aqueducts amounts to three hundred and fifty-nine and one-third miles: of which three hundred and four miles underground, fifty-five above ground, the channel being carried on the top of really triumphal arcades, at prodigious heights, exceeding sometimes one hundred feet. The quality of the waters was very different. Best of all were considered the Marcia, the Claudia, and the Virgo: worst of all the Anio Vetus and the Alsietina; these two were accordingly employed only for the irrigation of gardens and for washing away the drains; and were drunk only in cases of absolute necessity. As regards the temperature, the Marcia was the coldest, "Marsas nives et frigora ducens Marcia" as Statius sings. It marks 46° Fahrenheit at the spring of S. Lucia. Tacitus relates among the crazy exploits of Nero his attempt to profane the sacred spring by swimming across it from shore to shore. The pollution of the pure icy waters was revenged with a rheumatic fever, which brought the young emperor to the verge of death.

I have been asked many times the question why the Romans have spent such an amount of time, labor and money in building these prodigious channels across mountains and valleys, tunnelling the former and bridging over the latter with tunnels and bridges many miles long; when it would have been so easy and so economical to lay down pipes, following at a moderate depth the undulations of the country. In other words, I have been asked whether the Romans have known or not the use of syphons. To be sure they knew it, in theory and in practice. Well known are the syphons of Pataræ a Aspendas and Pamphilia, of Constantina in Mauretania, and of Lyons in Gaul. The finest and most daring of all is the syphon of Alatri, a town in the Nernici district built by a wealthy citizen, Betilienus Varus, a century and a half before the Christian era, and which was capable of supporting a pressure of ten atmospheres. As regards the main aqueducts supplying Rome with a daily supply of fifty-four million cubic feet of water, it would have been impossible to substitute metal pipes for channels of masonry, because the Romans did not know cast-iron, and no pipe, except of cast-iron, could have supported such enormous pressures. Let us rejoice, at any rate, at this state of things, because had the ancients known the contrivances of modern industry, we should most likely have been deprived of the loveliest sight which our Roman campagna offers.

Before leaving this interesting subject of the water-supply, I must make two more remarks; the first concerns the system so widely followed in our age of damming across the beds of rivers in mountainous regions, in order to create artificial lakes or reservoirs of pure water, from which the supply is derived. The ancients knew and followed this system on a magnificent scale. One of our aqueducts, the Anio Novus drew originally its supply directly from the river Aniene at a place forty miles distant from Rome. It happened that every time the river was swollen by rains, the aqueduct would carry down troubled and undrinkable water, which would fill up the channel with incrustations of carbonate of lime, and choke the minor pipes. To mend the matter, and to obtain a constant influx of pure water, the valley of the Anio was dammed, not once, but three times, across the picturesque gorge or cañon of the Simbruine mountains, between the modern town of Subiaco and the Benedictine abbey of the Sacro Speco, and three artificial lakes were thus obtained, in which the water was purified three times.

The second remark concerns the system employed by the ancients in boring and tunneling the mountains for hydraulic purposes. Two very curious documents have come down to us on this subject in connection, of course, with hydraulic enterprises. The first is the official report of the perforation of a tunnel, to bring down to Bougie, Algeria, (called then Civitas Salditane), the waters of a spring, fourteen miles distant, now called Aïn-Seur. The report, engraved on a marble altar discovered in 1866, near Lambæse, begins with a petition addressed in the year 152 by Varius Clemens, governor of Mauretania to Valerius Etruscus, governor of Numidia. The petition reads as follows: "Varius Clemens greets Valerius Etruscus, and begs him in his own name and in the name of the township of Saldæ to despatch at once the hydraulic engineer of the III legion, Nonius Datus,

with orders that he should finish the work, which he seems to have forgotten." The petition was favorably received by the governor and by the engineer, Nonius Datus, who having fulfilled his misson, wrote to the magistrate of Saldæ the following report:

"After leaving my quarters, I met with the brigands on my way, who robbed me even of my clothes and wounded me severely. I succeeded after the encounter in reaching Saldæ, where I was met by the governor, who, after allowing me some rest, took me to the tunnel. There I found everybody sad and despondent, they had given up all hopes that the two opposite sections of the tunnel should meet; because each section had already been excavated beyond the middle of the mountain without effecting the junction. As it always happens in these cases, the fault was attributed to the engineer, as if he had not taken all the precautions to insure the success of the work. What could I have done better? I began by surveying and taking the levels of the mountain: I marked most carefully the axis of the tunnel across the mountain; I drew plans and sections of the whole works, which plans I handed over to Petronius Celer, then governor of Mauretania, and to abound in extra precautions, I summoned the contractor and his workmen, and began the excavation in their presence, with the help of two gangs of experienced veterans, namely, of a detachment of marine-infantry (classicos milites), and of a detachment of Alpine troops (Gæsates). What could I have done more? Well, during the four years I was absent at Lambæse, expecting every day to hear the good tidings of the arrival of the waters at Saldæ, the contractor and the assistant had committed blunder upon blunder; on each advancing section of the tunnel they had diverged from the straight line, each towards his right hand side, and had I waited a little longer before coming, Saldæ would have possessed two tunnels instead of one.". Nonius Datus, having discovered the mistake, caused the two diverging arms to be united by a transverse channel; the waters of Ain-Seur could finally come across the mountain; and their arrival at Saldæ was celebrated with extraordinary rejoicings, in the presence of the governor Varius Clemens and of the engineer.

To come back to my Rome, however, the longest tunnel perforated in its vicinity for the sake of the water-supply is the one of Monte Affliano, between Tivoli and St. Gericomio, 4,950 metres long. Its boring was (by Domitian) intrusted to one of the Imperial contractors, L. Paquedius Festus. A daring and difficult work it was, especially on account of the difficulty of ventilation in a channel only seven feet high, three wide. The contractor, before commencing the perforation, made a vow to a goddess of local worship, named the Bona Dea, to restore her decayed temple on the top of the mountain if the enterprise should succeed. The two opposite sections met most successfully on July 3, 88. The beautiful columns and fragments of statuary discovered by us on the summit of Mount Affliano prove that the vow of L. Paquedius was not what is called the vow of a sailor.

The influence of this magnificent supply of water on the health of the inhabitants of Rome and the Campagna can be easily understood. There was no farm, no country-house, no villa, there was no cluster, however small and insignificant, of rustic population which could not be favored with copious fountains of icy-cold, salubrious water. Villages and towns, such as Ostia, Portus, Gabii, Borillæ, Veii, the ruins of which are scattered to-day in a waterless desert, were, in Roman times, almost overflowed, and their aqueducts can vie in length and magnificence with the main aqueducts of the capital.

As regards public cemeteries — another hot-bed of pestilence — their reform and regulation took place even later than the reform in the supply of water. I speak, of course, of *public* cemeteries for the burial of artisans, of slaves, and of the poorest classes of the population, because people belonging to higher classes usually provided themselves with private tombs, either within the precincts of their villas and farms, or on the border of high roads. It is impossible to conceive an idea of the horrors of a common *carnarium* or foss in the first centuries of Rome. I will give particulars of one only, which occupied a large district on the Esquiline, because these particulars have been discovered by myself, and have not yet been fully disclosed to the general public.

The Esquiline cemetery was divided in two sections: one for the artisans who could afford being buried apart in Columbaria, containing only a given number of cinerary urns; one for the slaves, beggars, prisoners, and so forth, who were thrown in revolting confusion into common pits or fosses. This latter section covered an area 1,000 feet long, 300 deep, and contained many hundred *puticuli* or vaults, 12 feet square, 30 deep, of which I have brought to light and examined about seventy-five. In many cases, the contents of each vault were reduced to a uniform mass of black, viscid, pestilent, unctuous matter; in a few cases the bones could be in a certain measure singled out and identified. You would hardly believe me when I say that men and beasts, bodies and carcasses, and any kind of unmentionable refuse of the town were heaped up in those dens. Fancy what must have been the condition of this hellish district in times of pestilence, when the mouths of the crypts must have been kept wide open the whole day! But there is still something worse. You have certainly heard of the great fortification which protected Rome on the east side, called the Agger, or Embankment of Servius Tullius, from the king who raised it. This fortification, more than one mile long, comprised a ditch or moat one hundred feet wide, thirty deep, with ramparts one hundred feet wide, thirty high, supported and strengthened on the outside by a lofty, battlemented wall. It seems, under the republican rule, and on the occasion of a stupendous mortality — to use the words of Livy — the portion of the huge moat which skirted the cemetery of the Esquiline was filled up with corpses, thrown down as if they were carrion, until the level of the embankment was reached. The discovery of these revolting particulars took place in 1876, under the circumstances which I am going to relate. In building the foundations of a house at the corner of Via Carlo-Alberto and Via Mazzini, the architect, lead into deception by the presence of a solid bed of tufa on the northern half of the building ground, began laying his masonry and filling up the trenches at the uniform depth of twelve feet under the level of the street. All of a sudden, the ground gave way, and one-half of the area was sunk into a chasm thirty feet deep. On careful examination of the circumstances of the catastrophe, it was ascertained that whereas the northern half of the foundations rested on the solid embankment or Agger of Servius Tullius, the southern

half had been laid on the site of the ditch, filled up with thousands upon thousands of corpses, which, being brought in contact with the air after twenty centuries, had sunk into dust or nothing, leaving open a huge chasm. According to measurements which I took at the time, this mass of human remains was, at least, one hundred and sixty feet long, one hundred wide, and thirty deep. Giving to each corpse an average space of twenty cubic feet, which is more than sufficient, there were, at least, twenty-four thousand bodies in a comparatively small space.

As if all the evils described were not deemed enough, the town authorities had increased their efficiency by allowing the daily refuse of a population, numbering nearly a million souls, to be heaped up within and around the precincts of this Equiline cemetery. In later times, seven centuries after the foundation of Rome, they endeavored to stop the practice, or at least to regulate it. Decree upon decree was issued on the subject, and a line of stone cippi inscribed with sanitary rules was set up around the edge of the pestiferous ground. I have found three of these police regulations, engraved on square blocks of travertine. Here is the text of one: "C. Sentius, son of Caius, Prætor, by order of the Senate has set up this line of terminal stones, to mark the extent of ground which must be kept absolutely free from dirt and from carcasses and corpses. Here also the burning of corpses is strictly forbidden." Another hand, probably the hand of a man living in the neighborhood and within reach of the effluvia of the place, has written in huge red letters the following entreaty at the foot of the official decree, "Do carry the dirt a little farther; otherwise you will be fined." Couldyou believe that this line of stones, beyond which the refuse of the town could be legally thrown and be allowed to putrify under the burning sun, was only four hundred feet distant from the walls and embankment of Servius Tullius? And would you believe that on the day of the discovery of the above-mentioned stone, June 25th, 1884, I was obliged to relieve each quarter of an hour my gang of workmen, because the smell from that polluted ground (turned up after a putrefaction of twenty centuries) was absolutely offensive and unbearable even for men so hardened to any kind of hardship as my excavators.

The reform in this branch of public hygiene, the suppression of the popular cemetery on the Esquiline, took place only under Augustus, at the suggestion of his enlightened prime minister, C. Cilnius Mæcenas. He obtained from his sovereign and friend the concession of the whole district; buried it under an embankment of pure earth, twenty-five feet high, and a third of a square mile in surface, and on the newly-made ground he laid down his magnificent gardens, the world-known *Horti Maecenatiani*, of which I shall speak at length in one of my next lectures. The event proved to be of such unexpected importance for the improvement of the health of Rome, that Horace himself, the brilliant court poet, thought it worth being sung by his muse:

> Nunc licet Esquiliis habitare salubribus, atque
> Aggere in aprico spatiari, quo modo tristes
> Albis informem spectabant ossibus agrum (Sat. I, 8, 14).

I shall not mention other improvements carried on with the progress of Roman civilization, such as the paving of the streets, the opening of a thick network of roads in the Campagna, the drainage of damp districts, the spreading of suburbs, the careful cultivation of the soil, and so forth; because I shall have occasion to speak of these particulars in my lecture on the Campagna. One subject deserves more attention, because it is little known, the subject of medical attendance either public or private, which attendance is one of the most important factors in the sanitary arrangements of a civilized nation.

(To be continued.)

SPINAL IRRITATION, ITS SYMPTOMS, PATHOLOGY AND TREATMENT.

BY J. LEONARD CORNING, M.D., NEW YORK,
Consultant in Nervous Diseases to St. Francis Hospital, etc.

This affection occurs frequently among both women and men, but its diagnosis is often a matter of some difficulty, owing to the fact that it is sometimes found in conjunction with other affections, as, for example, hysteria and neuralgia. The symptoms, observed in a typical case are, however, so characteristic, that they may reasonably be ascribed to a distinct pathological condition.

Symptoms. Like spinal exhaustion the affection develops gradually in the majority of cases. The first symptoms to appear are vague pains in the dorsal region along the course of the vertebral column. These pains are usually provoked by even slight fatigue, such as that induced by rapid walking or riding. Sometimes the subject complains in the beginning of dull burning sensations between the shoulder blades or at the base of the neck; but whatever the character of the initiatory symptoms may be, the pains in the back become more and more severe in character, and conjointly with these there is almost always marked mental irritability. If at this time an examination be made, certain regions along the course of the vertebral column will be found extremely sensitive to pressure or tapping. A sponge, saturated with hot water, passed along the course of the spinal column, evokes painful sensations; while the wire brush employed in conjunction with the faradic battery, often discloses painful spots, which pressure and the hot sponge fail to reveal. I regard an electrical test of the degree of sensitiveness as of great importance in this and all other forms of obscure spinal affections; indeed, by the employment of this method of investigation, I have frequently succeeded in discovering sensitive areas, which, though exceedingly painful, had failed to reveal themselves upon pressure or percussion. I lay stress upon this point merely because I believe that far too much importance has been ascribed to the results obtainable by digital pressure and percussion. In the more exquisite cases, however, the morbid sensitiveness is so obvious that delicate tests are superfluous. Under these circumstances the friction caused by the clothing is often intolerable, while the passage of the finger along the course of the vertebral column reveals hyperæsthetic areas of the integument, which may be of great extent, or circumscribed in character.

Besides the condition of hyperæsthesia, various paræsthesiæ, such as burning sensations, formication, tingling, and alternating feelings of hot and cold are

frequently met with. On the other hand, absolute paralysis and anæsthesia are absent. Disturbances of motility, when they exist, merely consist in a lack of capacity for the performance of operations requiring endurance; — the patient is soon weary, and even moderate use of the muscles is liable to provoke amblitory pains, which, though often intense in character, wander from one portion of the body to another in the most unaccountable manner. Sometimes the subject complains of neuralgiform pains in the face and head, or in the upper or lower extremities; but hardly have these sensations become established, when they gradually, and in some cases suddenly, disappear, only, however, to reappear in the form of vague, visceral, genital or vesical pains. These unstable pains are extremely characteristic, and often give rise to great discomfort and apprehension on the part of the patient, as well as confusion in the diagnosis.

Local spasms are a frequent concomitant of irritable spine. Sometimes they assume the form of fibrillary twitchings, located in single muscles, whereas in another and larger class of cases spasms are widely distributed, involving entire groups of muscles. There is nothing of a violent or epileptoid character in these phenomena; they are usually evanescent in character and disappear under the influence of appropriate treatment. It may readily be conceived that the location of the symptoms exhibited in each case will depend upon whether the functional disturbance is found at the superior, dorsal, or dorso-lumbar portion of the cord.

Thus, if tenderness be found at the cervical portion of the cord, the subject is liable to exhibit vaso-motor disturbances manifesting themselves in sudden blushing and facial pallor upon slight provocation, or in an habitual frigidity of the extremities. Again, if there be hyperæsthesia above the dorsal segments of the vertebral column, digestive and other disturbances are usually present; while should the lumbar portions of the cord be functionally disturbed, vesical derangements, in the form of an increased and frequent desire to urinate give rise to the erroneous supposition that there is paralysis of the sphincter. Should the functional efficiency of the cord be more or less affected throughout its entire extent, the complex of symptoms is greatly amplified — there are palpitations, dyspepsia, spermatorrhœa, vaso-motor disturbances, fibillary twitchings, sleeplessness and great psychical irritability.

Spinal irritation, though a functional affection, is sometimes exceedingly obstinate in character; and even when we succeed in abating or removing the symptoms, they are prone to return. Nevertheless, there is no doubt, that in the vast majority of cases the disease is amenable to treatment, provided the therapeutic measures employed are appropriate, and at the same time rigidly adhered to, even after the symptoms have entirely disappeared.

Pathology. The pathology of spinal irritation is not as satisfactory as might be desired, owing in part to the defective manner in which the few autopsies on record have been conducted, and in part to the extreme difficulty of obtaining post-mortem examinations in this, as in other benignant nervous affections. Some writers entertain the belief that the symptoms are wholly attributable to hyperæmia of the cord, while other observers are equally convinced that anæmia is the true source of the phenomena. For my own part I am entirely of the opinion that the posterior columns, and more particularly those districts of the same, known as the posterior root zones, or columns of Burdach, are involved, and I can also conceive that the posterior horn is implicated, whether the circulatory condition present is one of hyperæmia or anæmia, I am by no means prepared to say with certainty. Of this, however, I am thoroughly persuaded, that the nervous elements themselves are in a state of abnormal irritability, whatever the condition of the circulation may be. And I believe, moreover, that the question of primary importance in treatment is the removal of such irritability by appropriate measures; and that having once accomplished this, we may confidently anticipate a corresponding amelioration in the vascular condition, be the same one of anæmia, hyperæmia or alternate hyperæmia and anæmia.[1] My views in this respect receive substantial support from the well-known relationship of the blood-stream to all active tissues. Further careful clinical and pathological observations may perhaps serve to increase our knowledge respecting the intricate morphological questions involved.

Diagnosis. It is undeniable that spinal irritation is an affection often extremely difficult of accurate diagnosis; at least, this is true of the less typical cases. Where, however, the symptoms are well marked, less difficulty will be experienced in forming a correct conclusion as to the true nature of the affection.

The differentiation of spinal irritation from *hysteria* is, in a large number of cases, exceedingly difficult. This inability to differentiate the two conditions in certain cases does not, however, seriously interfere with the plan of treatment; for, it is but reasonable to infer, that where the symptoms of two diseases are so inextricably blended, there must be a corresponding fusion of pathological causes. On the whole, therefore, the opinion that hysteria and spinal irritation, though separate affections, are frequently associated in one and the same individual, seems plausible. Where, however, the predominant symptoms of hysteria, general spasms, globus, and paralytic phenomena are found in conjunction with only minor indications of spinal irritation, the case should be adjudged one of hysteria.

From *spinal exhaustion*, the affection under consideration differs in this: that in the latter disorder, disturbances of sensibility predominate, whereas, in the former, marked diminution of the functional resources of the cord is the characteristic feature.

Locomotor ataxia and *myelitis*, even in their earlier stages, are not readily confounded with spinal irritation, since the lancinating pains, incoördination, and girdling sensations peculiar to ataxia are wanting; and the same may be said of the anæsthesia, paralysis of the bladder and voluntary muscles of the limbs and contractures, which are so characteristic of the latter affection.

Spinal irritation is difficult to differentiate from *hyperæmia* of the cord, except when the hyperæmia is sufficiently intense to cause paralysis. It has been urged by a medical writer of distinction[2] that "spinal irritation is made worse by the administration of ergot. . . . The reverse is true of strychnia, which, in all cases, aggravates the symptoms of myelitis, meningitis,

[1] Vide: Views of Beard and Rockwell; Treatise on Medical and Surgical Electricity. Second edition. pp. 450. New York. 1875.

[2] "A Treatise on the Diseases of the Nervous System." By William A. Hammond. Page 47, seventh edition, 1881.

or congestion, while it is an efficient means of cure in spinal irritation." My own experience does not accord with the above; indeed, it leads me to a diametrically opposite conclusion. At this very moment, I have under my care a gentleman manifesting all the appearances of spinal irritation, in whom the symptoms of the affection are greatly aggravated by strychnia in doses of one forty-eighth of a grain. This phenomenon is readily explained if we admit that the sensory districts of the cord are in a state of erethism. It is a matter of secondary importance whether this condition of irritability is *accompanied* by a hyperæmic or anæmic state of the cord or not.

Meningeal tumors, during their early stages, may doubtless give rise to symptoms closely resembling those induced by spinal irritation. But the disturbances produced by tumors are stable in character, and confine themselves with more or less strictness to certain districts, whereas, the migratory character of the symptoms of spinal irritation constitutes a distinctive feature.

On the whole, therefore, where severe pain of an amblitory character exists in the spine, accompanied by great tenderness of the spinous processes, but without paralysis, anæsthesia, or other severe symptom pointing to grave organic trouble, it is safe to assume that we have to do with a case of spinal irritation.

Treatment. In the treatment of spinal irritation, the attention of the physician should be directed to those symptoms which owe their origin to the functional derangement of the cord, on the one hand, and to those manifestly attributable to a secondary condition of cerebral erethism on the other.

The removal of the local hyperæsthetic spots, though often a protracted operation, is usually attainable by the employment of a sufficient amount of patience, conjoined with appropriate local measures. Among these have been recommended counter irritation by means of blisters, or the actual cautery. I cannot say I resort to these measures as much as formerly, for reasons which I will presently state. On the other hand, the application of the galvanic current to the spine, one electrode being placed two or three inches above the painful point, and the other an equal distance below it, will be found of service in many instances. The applications should last from fifteen minutes to half an hour, and should be undertaken at least once a day. General faradization also yields excellent results, especially in cases of debility and anæmia. Of internal remedies, iron, quinine, and zinc will be found most useful, where the condition of the stomach will permit the employment of medicine.

Neuralgic pains, stomachic difficulties, and other complications should be treated symptomatically in the order of their occurrence. We have already alluded to the secondary condition of cerebral erethism, manifesting itself in insomnia and extreme mental irritability. These latter symptoms exert an exceedingly prejudicial influence upon the general health of the patient, and serve to sensibly diminish the prospects of a speedy recovery; and they should, therefore, claim the particular attention of the attending physician. For an extended account of the measures to be adopted in the treatment of the various derangements of sleep, I would refer to the special monograph upon that subject by the author of this paper.[3] As regards the irritability, we would recommend the employment of the bromides, Mariani's coca wine, and, where there is no tendency to vaso-motor derangements (cerebral hyperæmia), stimulants may be administered in moderate quantities. And here, I would enter a protest against the extravagant and hysterical utterances of certain persons regarding what they conceive as dangerous attributes of the coca-preparations. In this matter, I agree with Hammond, that there is no foundation, whatever, for this extreme apprehensiveness. I usually give brandy, whiskey, or rum; or, where the stomach will bear it, Burgundy or Bordeaux, which may be taken at dinner. The administration of stimulants is, however, often impossible, owing to extreme susceptibility.

After treating several cases, the physician inevitably becomes aware of the fact that in a certain proportion, his efforts do not meet with complete success; there is, in a word, an inordinate persistence of soreness and pain on pressure above the vertebræ — a condition discouraging at once to physician and patient. In such cases, I have frequently resorted to local medication of the cord by means of deep injections between the vertebræ of the hydrochlorate of cocaine, in solutions of varying strength. The hyperæsthetic spots are those which I usually select for the injections, but I have no hesitancy in making from six to one dozen or more such injections along the course of the spine. Care should be exercised, in making these injections, to place the needle as near the ligamentum insterspinosum as is consistent with a prudent desire to avoid wounding the cord.[4]

The results obtained by this plan of treatment are often astonishingly favorable; and it is matter of surprise to me that in the face of the excellent effects obtained by local medication of nerves, literature contained nothing concerning the application of this principle previous to publication of my first paper.[5] I will merely add that in the *New York Medical Journal* for November 6, 1886, I have described a painless method of anæsthetizing the skin which I believe is destined to prove an important aid in the treatment of hyperæsthetic conditions of the nervous system. At an early day, I purpose publishing a still more explicit account of this method, embodying a wide range of cases. I need only observe that various other medicaments may be employed in the same way.

Finally, it must not be forgotten that this and similar functional affections of the cord exhibit, in spite of the apparently benignant nature of their pathology, a pertinacity which is often in the highest degree trying to patient and physician alike. Perseverance and minute attention to the various phases of each case will often, however, accomplish wonders.

[3] "Brain Rest, being a Disquisition on the Curative Properties of Prolonged Sleep." By J. Leonard Corning, M.D. New York: G. P. Putnam's Sons. 1885. Second edition, page 36, *et seq.*

[4] For the benefit of those who are interested in the development of more potent methods of affecting the cord in disease of the brain, I would refer to my article contained in the New York Medical Journal for October 31, 1885, and also to my monograph on "Local Anæsthesia." New York: D. Appleton & Co. 1886.

[5] Op. cit.

— Among the replies to an advertisement of a musical committee for "a candidate as organist, music-teacher, etc.," was the following one, "Gentlemen — I noticed your advertisement for an organist and music-teacher, either lady or gentleman. Having been both for several years, I offer you my services." An exchange inquires very naturally if this was a hermaphrodite?

NOTES ON THE TREATMENT OF STONE IN THE BLADDER.[1]

BY A. T. CABOT, M.D.,
Surgeon to the Massachusetts General Hospital. Surgeon to the Boston Children's Hospital.

RECURRENCE OF STONE.

NOT infrequently after the removal of a stone another one forms in a shorter or longer time; and this may come about in one of four ways, which we will consider *seriatim:*

I. A uric-acid stone may be followed by another, on account of the persistence or reappearance of the uric-acid diathesis. The same may be true, though less commonly, in the case of an oxalic stone.

Cases 14 and 15 furnish good instances of the recurrence of uric-acid calculi.

Case 14 was that of a man of fifty, who was first troubled in 1876 by the occasional passage of small stones. He was operated on by lithotrity in several sittings, and was then free until 1883, when his symptoms returned, and he was operated upon then, and again in 1884 by litholapaxy. Several small stones were removed at each operation, and each time he had a considerable period of relief from symptoms. I saw him first in December, 1885, at which time he was again passing small stones, and, by litholapaxy, I removed two uric-acid calculi, of about twelve grains each.

Case 15 is that of a man seventy-five years old, who was relieved of a stone by Dr. Bigelow in 1868 by lithotrity, in two sittings. When I saw him in February, 1886, his trouble had recently returned, and I removed a uric-acid stone weighing nineteen grains.

To prevent this sort of recurrence, patients who have once suffered from a uric-acid or oxalate-of-lime calculus should be instructed in regard to the dietetic and hygienic precautions, which will be likely to counteract a tendency to excessive uric-acid formation. Sugar in every form is harmful in these cases, as are also all fatty articles of food, and rich, highly-seasoned dishes. These should, accordingly, be avoided. Malt liquors and wine, especially the sweeter varieties, should be given up, and if the stimulant effect of alcohol is desired, spirits largely diluted should be preferred.

Systematic exercise should be taken, if possible sufficiently violent to excite moderate perspiration, and the skin should be cared for by regular bathing and vigorous rubbing. If the patient is constipated, his bowels should be regulated, and this may well be done by a morning glass of Friedrichshall or Carlsbad water. Thompson recommends a long course of saline waters for these patients with uric-acid tendencies, and regards their effect as due to a stimulant action upon the liver. Whatever the *rationale* of their use, they are of undoubted benefit when a constipated habit exists.

Where uric-acid crystals are abundant in the urine, and the danger of stone formation is imminent, alkaline diuretics, by correcting the over-acidity of the water, may be of temporary benefit and tide over the danger for that time, but without the addition of general treatment, the uric acid quickly returns upon their disuse.

II. A soft, phosphatic stone may be reproduced after removal, if the chronic cystitis and alkaline condition of the urine which led to its original formation persists. This is not infrequently seen in those cases where an obstruction to the complete emptying of the bladder perpetuates the fermentation of the urine.

Cases 1, 2, and 13 furnish instances of the recurrence of soft, phosphatic stones. Cases 1 and 2, which were operations upon the same patient, have been reported at length in the *Boston Medical and Surgical Journal* for August 28, 1884.

The patient was a man of sixty-five, with an enlarged prostate, which did not allow of the passage of any urine without the aid of a catheter. In May, 1883, a small, soft stone was removed by Dr. Bigelow, the patient returning the next day to the country. In November, 1883, I removed a large number of small calculi, and he was for several months free from discomfort, and his urine was almost clear. He then had an attack of cystitis; his pain returned, and in July, 1884, I again removed a number of small calculi.

Eighteen days later, the alkaline condition of the urine having persisted, the bladder was washed out with the evacuator, and over two hundred little stones, which, altogether, weighed but fourteen and a half grains, were removed. A fortnight later, another washing obtained over a hundred of these little calculi, and six days later, thirty more were pumped out. The urine had now cleared up considerably, and subsequent washings failed to find any more calculi. The separate accretion of all of these little stones about different foci shows how great the tendency in this case to stone formation.

Case 15. A man of sixty, with prostatic obstruction and residual urine, had a stone weighing one hundred and forty grains removed. A subsequent washing with the evacuator did not find any sand or fragments, but he insisted on leaving the hospital before the urine was clear of pus, or had lost its alkalinity. He neglected the daily irrigation of the bladder, which was advised, and, as I afterwards heard, he appeared five months later at the City Hospital, and had a small stone crushed. In answer to an inquiry of mine, Dr. M. F. Gavin, who operated upon him at this time, kindly wrote me as follows: "In M.'s case, the stone was small, and so soft that the moment the crusher seized it, the sense of resistance disappeared. The bladder was washed ont, bringing away a quantity of detritus; no fragments. There was no evidence present of any old fragments."

It is evident that, to prevent this sort of recurrence, it is important to entirely relieve the cystitis before allowing the patient to pass from under treatment, and then to send him away with a clear understanding of the importance of immediately correcting any tendency to alkalinity and pus formation.

When an obstructed urethra is the cause of the cystitis, the obstruction should be relieved if possible. If this cannot be accomplished, as often happens in the case of an enlarged prostate, the evils of retained urine must be lessened as far as possible, by systematic catheterization.

The moment that any considerable amount of mucus or other evidence of commencing fermentation appears in the urine of one of these patients, thorough irrigation of the bladder must be instituted and kept up, until the normal condition is again reached.

A good deal may also be accomplished by internal medication in clearing up urine which has become foul and ammoniacal. The occasional usefulness of

[1] Concluded from page 520.

many diuretics is well known, and buchu, uva ursi, triticum repens, citrate of potash, and even the free use of clear spring water will often help to bring about a good result.

Some drugs are thought to have even a more direct action in reducing fermentation. Benzoic acid and its salts have some reputation in this regard, and I have used them in many cases with good effect. Sometimes, however for no apparent reason, they utterly fail, and they have the occasional disadvantage of disturbing the stomach. Eucalyptus oil is also exhibited to check fermentation in the urine. Bartholow ascribes to it great efficacy.

III. Sometimes the successive escape of several stones from the kidney gives rise to several consecutive attacks of stone in the bladder.

The treatment proper for stone in the kidney is appropriate here, together with the prompt removal of the stone when its presence in the bladder is manifest.

IV. Lastly, if a fragment is left after an operation, it may serve as a nucleus for another stone.

The danger of this mischance is greatly increased by any obstruction to the flow of urine, such as is caused by an enlarged prostate. The bladder in such a case is usually sacculated so that fragments are more likely to escape removal by the evacuator, and if a fragment is left it is very unlikely to be afterwards voided by the natural efforts of the bladder, but remains in the residual urine.

In a healthy condition of the bladder, when the urine is thoroughly expelled at each act of micturition the retention of a fragment of small size is not likely to occur.

Case 16 is an instance of a second operation on a patient in whom a minute fragment was left at a previous crushing.

The patient, a man of seventy-four with almost complete obstruction to micturition and a dilated, sacculated bladder, was first operated upon by me in June 1885. At that time a small stone was removed which was itself a fragment of a considerable stone which had been crushed and pumped out by a surgeon at his home in New Brunswick. Subsequent attempts to crush this fragment had failed, and he consequently sought advice from Prof. H. J. Bigelow, who kindly referred him to me.

The fragment in question was very hard to seize with the lithotrite, and it was only when the bladder was almost emptied of water that it could finally be grasped and crushed. The urine cleared up rapidly and he left the hospital apparently free from bladder symptoms, except so much as would naturally be caused by the persisting obstructions in the prostate.

He returned in March, 1886, in very much better health than when he left us, and with a gain of thirty pounds in weight. He again, however, showed symptoms of calculus, and on March 30, 1886, I crushed and removed a stone weighing thirty-four grains, which had as a nucleus a little crumb from the earlier stone which was somewhat darker in color than the surrounding crust. After this operation, he went home well and has remained so.

As a guard against the retention of fragments, as in this case, the bladder should always be washed out with the evacuator one or more times after the operation, before discharging the patient. This can readily be done without ether.

In using the pump the sacculated character of many of these bladders should be remembered, and a careful search should be made lest a fragment be caught and held in some side pocket. The orifice of the evacuating tube should be turned successively towards each part of the cavity in order to dislodge with the current any such fragment.

It has been urged against litholapaxy that recurrences are specially liable to take place after it, and I have therefore spoken somewhat at length of the precautions which will render the retention of a fragment almost impossible. This is the only cause of recurrence which can fairly be laid at the door of the operation, and it is one from which lithotomy is not exempt. The difficulty of removing the last fragments when a soft stone breaks in the lithotomy forceps is notorious.

The other causes of recurrence are common to every operation, and I have tried to emphasize the importance of first correcting the faulty condition, which made the formation of the stone possible, and then of making each patient understand the future dangers and how they are to be avoided.

LITHOLAPAXY IN THE FEMALE BLADDER.

Case 22 was an instance of this. Some difficulty was anticipated in the matter of seizing fragments, as in women the presence of the uterus behind the bladder makes the posterior wall of the latter irregular and flatter than in man, so that fragments lying upon it would not naturally gravitate to the centre as in the male bladder.

When using the lithotrite at an angle of forty-five degrees the expected difficulty was met. But it was found that when the handle of the instrument was raised to a vertical position, the blades rested on the yielding vaginal wall close to the urethral entrance, and by depressing this made it the most dependent part of the bladder, into which the fragments gravitated and where they were readily seized.

The operation went quickly and easily, without any injury to the urethra, and convalescence was rapid and satisfactory.

FISTULA AFTER LATERAL LITHOTOMY.

Case 3 furnishes an instance of one of the accidents which may follow lateral lithotomy. The patient, a boy of ten, was cut on November 11th, 1884, and a very rough mulberry calculus was removed. The incision entered the urethra a little further forward than was necessary, somewhere about the entrance to the membranous portion. The wound healed slowly and left a fistulous opening through which a small amount of urine escaped at each micturition. There was also a slight involuntary leakage when the bladder was full. After this had persisted for several weeks it was thought probable that the wound in healing had left a slight stricture in front of the fistula, which by its obstruction to the natural flow of urine constantly forced some of it through the opening. An examination showed this to be the case, and the passage of bougies for a few weeks relieved the stricture and brought about a healing of the fistula.

CALCULUS WITH SHOE-STRING NUCLEUS.

Case 10 was interesting in that a leather shoe-string formed the nucleus of the stone. The patient was a young man of twenty, who in October, 1885, came up from New Brunswick with symptoms of stone which had troubled him since the previous spring.

A stone being felt, he was etherized and it was easily seized and crushed.

At the first withdrawal of the lithotrite, its jaws came out clogged with bits of a leather shoe-string. Other short bits were pumped out with the débris of the stone and again other portions were removed with the lithotrite. At the end of the operation 113 grains of calculus matter and eight inches of string had been obtained.

It was subsequently learned from the patient that during the previous April he had been confined to bed by a sore foot and finding it hard to pass water had improvised a bougie and had let it slip from his fingers into the bladder. He had not before mentioned the fact to his physician because he supposed that the string had long since dissolved.

STRICTURE OF THE URETHRA COMPLICATING LITHOLAPAXY.

In Cases 7 and 18 a stricture of the urethra complicated the operation. In both instances the stricture was divulsed and the litholapaxy was at once proceeded with; no difficulty being met in its performance and there being no subsequent ill-effects during convalescence. Dr. Bigelow has shown by many successful cases that these two operations may be safely and advantageously combined in one sitting.

Case 21 was an example of a still further complication. This patient not only had a close stricture, but also had several false passages starting from the urethra in front of it; these resulted from previous attempts to reach the bladder. After divulsion of the stricture these pockets so interfered with the introduction of instruments that it became evident that the large calculus which was found could not be safely removed through the urethra, and consequently suprapubic lithotomy was resorted to.

For a full account of this case, see *Boston Medical and Surgical Journal*, November 11th, 1886.

REPORT OF PROGRESS RELATING TO FOOD AND DRUGS.

BY B. F. DAVENPORT, M.D., OF BOSTON.

ADULTERATIONS IN WINE AND SPIRITS.

THE following comment, made by Dr. S. W. Abbott in the late Public Health Supplement to the Seventh Annual Report of the State Board of Health, upon the report of the analyst on his examination of over one hundred samples of wine and distilled spirits, of which but ten were found to fairly be what they claimed to be, is of general interest to the profession: Noting that the principal adulterants were found to be alcohol, water, sugar, fruit extracts, and flavoring ethers, and that in no case was any ingredient found more harmful than the alcohol itself, he adds: "These examinations have also shown the falsity of a popular impression, which has been created and fostered by the ill-advised statements of public lecturers, and also published documents that the harmful effect of the habitual use of alcoholic stimulants is due to the adulterations to which they are subjected, rather than to the alcohol which they contain. It is sufficient to say that such statements have no foundation in fact, nor are they in the interest of justice, temperance, or truth."

LEAD IN HAIR DYES, AND MORPHINE IN OPIUM-HABIT CURES.

In the same reports, he also notes the large number of hair dyes found by the analyst to contain lead, and that almost all the so-called opium habit "cures" or "antidotes" so extensively advertised throughout the country were found by the analyst to contain morphine, the very thing for the use of which they had been so falsely lauded, and, therefore, were being so vainly used.

HOPEINE.

A new narcotic substance, under the name of hopeine, has been placed upon the London market as a substitute for morphine and quinine by a firm, who claimed that it was an alkaloid obtained by them from hops, and that they had found it present in the largest quantities in the wild hops of Central America. The substance is not found in German hops. On chemical analysis, Dr. Paul and others have found the substance to be of a variable nature, but that it usually corresponded to an admixture of two parts of morphine with one of cocaine, and he characterizes the attempt to introduce upon a pseudo-scientific basis an article that is only a mixture of two well-known substances as a piece of foolish impudence that almost passes belief. Moreover, Dr. A. Gray states that the wild hop grows so sparingly that he had never seen it where he could have gathered a single pound of the dried hops.

EULYLYPTOL.

A preparation, under the name of eulylyptol, has been recommended in *Journ. Pharm.*, October 15, p. 361, by Dr. Schmeltz, as an antiseptic preferable to iodoform, corrosive sublimate, or carbolic acid. It consists of a mixture of six parts of salicylic acid and one each of carbolic acid and oil of eucalyptus. The carbolic acid seems to enter into a chemical union with the other ingredients, and is not to be found in a free state. The mixture has a strong aromatic odor, and an acrid burning taste. It is nearly insoluble in water, but readily soluble in strong alcohol, ether, chloroform, and in alcohol and glycerine. It is also soluble in ammonia and alkaline solutions. According to Dr. Schmeltz, it completely arrests the fermentation of all putrescible substances. It will preserve urine for months. In many respects it seems to resemble salol, the new antiseptic produced by Prof. von Mencki, reported favorably upon by M. Sohli in *La Semaine Médecale*, April 14, 1886, and recommended as preferable to the usual forms in which salicylic acid is used is the treatment of rheumatism.

NATIONAL FORMULARY.[1]

Under the auspices of the American Pharmaceutical Association, a committee has been appointed, consisting of five pharmacists resident in New York City and Brooklyn, and one representative from each of the State Pharmaceutical Association, to prepare a standard and recognized guide for the preparation of such compounds as are not officinal in our National Pharmacopœia, but which are above the level of mere trade-receipts, and are not of a trivial or improper character.

The special committee presented a report at the late meeting of the Association, containing the following propositions: "Scope of the National Formulary — The National Formulary, to be published under the authority of the American Pharmaceutical Association,

[1] American Druggist, October, 1886.

may contain the formulas of such preparations as have either been formerly officinal in the United States Pharmacopœia and have been discarded, though still in demand, or such as have never been officinal, but deserve recognition, because more or less generally in use. Among the latter may be any preparations contained in foreign pharmacopœias, if there is known to be a sufficient demand for them in any section of this country. It shall also contain the preparations belonging to so-called "elegant pharmacy," but it shall not be encumbered with purely technical, trivial, or fancy preparations."

Reports of Societies.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES M. GREEN, M.D., SECRETARY.

October 9, 1886, the President, Dr. A. D. Sinclair, in the chair.

EXTRAORDINARY CARDIAC EXCITEMENT BEFORE A FIRST MENSTRUATION.

Dr. Draper reported the following case: The patient was an overgrown, nervous, well-developed girl, aged thirteen years and two months. Two years ago she was under medical treatment for chorea. During the past three years she had not attended school. Recently, her health had been satisfactory, and it was the intention that she should presently resume school discipline. Her mind was undeveloped and her tastes were childish; she liked the plays and companionship of little girls much younger than herself. She had never menstruated.

In the night of July 1st, she was restless and uneasy, sleeping but little. Her mother attributed the unrest to a somewhat later and heartier supper than she was accustomed to and recalled also that the girl exercised rather more vigorously than usual after supper. Dr. Draper saw the patient at 3.30, A.M., July 2d. She was tossing, restless, anxious, and irritable. She complained of pain in her left side and of the "thumping" of her heart. There was an occasional short, dry cough,—the familiar cough of cardiac palpitation. The hand over the heart detected a rapid but regular and not violent action of that organ. The stethoscope discovered no abnormal sounds; the rapid action was the only abnormality. There was no irregularity or intermission, then or later. The heart-beats, at this visit and subsequently (on one occasion verified in consultation) were counted as follows:

July 2d, 3.30, A.M.	212	July 4th, 9.30, A.M.	234
" 2d, 7.30, P.M.	222	" 4th, 5.15, P.M.	230
" 3d, 10, A.M.	228	" 5th, A.M.	98.
" 3d, 5.30, P.M.	236	" 6th, A.M.	80.

The highest temperature which the thermometer recorded meanwhile was 100.5° in the afternoon of July 2d.

The culmination of the case was reached July 5th, in the afternoon of which day menstruation began in a perfectly normal manner, without pain or other disorder. The pulse quickly regained its normal rate and kept it thenceforward. In August and September there was no recurrence, either of the catamenia or of cardiac disturbance.

During the three days, July 2d, 3d, and 4th, various measures directed to the control of the heart were wholly negative in their effect. Rest in bed, low diet, counter-irritants, emetics, cardiac sedatives and stimulants (aconite, veratrum, digitalis), proved unavailing; but with the premonitory indications of the menstrual function the heart resumed its natural action.

AXILLARY LYMPHANGITIS WITH LYMPHORRHAGIA? OR SUPERNUMERARY MAMMA WITH LACTEAL SECRETION?

Dr. A. H. Johnson, of Salem, reported, by invitation, the following case of axillary tumor coincident with pregnancy:

Mrs. S., already the mother of two children, was expecting her third confinement during the first week in August, 1886. Some time in April she discovered a lump in the right axilla. Although it grew each week very noticeably, she made no mention of it to her friends. During the second week in July it was accidently discovered by her husband, who at once called me to examine it. I called on the 11th of July and found in the right axilla a pendulous tumor bearing a close resemblance to a male scrotum. It was pear-shaped and somewhat flattened by compression between the arm and the chest. Its constricted base seemed but slightly adherent to the subjacent tissues. The skin covering it was thin, but loose. Around its base was the growth of hair belonging to the axilla. When taken in the hand and squeezed, the upper portion of it felt much like a varicocele, while distributed in its mass, irregular semi-elastic lumps could be felt, varying from one and a half inches long and three-fourths of an inch in width, to one inch in length and one-fourth or one-half an inch in width. It seemed like a growth made up of irregular, elongated and semi-fluctuating lobules of fat. It was painless and gave but little inconvenience. Owing to its harmless character treatment was deferred until after delivery. The patient was not seen again until the 4th of August, the day of her confinement. During the little more than three weeks since my first examination, it had increased about one-third in size, and another lump the size of an English walnut had appeared in the left axilla. After a comparatively easy and natural delivery, with the distention of the breasts, the tumor in the axilla enlarged. It became tense, tender, smooth, and slightly reddened; and measured nine inches in circumference. As the breasts yielded their milk the tumor grew softer and smaller, and at the end of a week was reduced about one-fourth in size. Seventeen days after delivery I was called to explain a new feature of the growth, and learned that the patient had for several days found her clothing about the right side of her chest quite wet. The source of this moisture was traced to the axilla. It was then discovered that when the tumor was squeezed there issued from four or more minute openings, scarcely perceptible to the naked eye, a fluid resembling milk. From that day to the time of this report the tumor becomes a little distended when the breasts are full, just previous to nursing the child, and when pressed continues to yield a milky fluid in small quantities. The smaller lump in the left axilla has disappeared. Is this a case of lymphangitis with lymphorrhagia or a case of supernumerary mamma? If the latter, why was there no such development of these glands in the two previous pregnancies?

Dr. Johnson subsequently made the following additional report:

Soon after the last meeting I took from our patient, in separate bottles, two samples of lacteal fluid, one from the breast and the other from the axillary tumor, and examined them with the microscope. The fluid from the tumor is to the naked eye a much thicker and cream-like liquid than the thin bluish breast-milk. Under the microscope the specimen from the axillary glands reveals in addition to the finely emulcified fat of the breast-milk, a coarser emulsion of fat with large colostrum cells, the whole field being crowded with these more solid constituents of milk.

Soon after my return to Salem I found in the "Quarterly Compendium of Medical Science" a report of a paper on the "Development of Mammary Functions by the Skin of Lying-in-Women," which was contributed by Dr. F. H. Champreys to the Royal Medical and Chirurgical Society. In this paper the author reports thirty cases which had occurred in the General Lying-in Hospital, all illustrating the title of his paper. In it he says that "the cases of axillary lumps are believed to be now described for the first time." "They seem to prove that in lying-in women the sebaceous follicles of the skin are capable of producing true mammary secretions." . . . "They confirm the opinion that the breast is a highly specialized aggregation of highly specialized sebaceous follicles." "Dr. G. D. Pollock believed that this was the first paper that had been contributed upon this subject." Dr. Creighton "believed that the lumps or glands were not derived from *sebaceous* glands, but from another cutaneous structure that existed in the human axilla. He had incidentally described the glandular stratum in a paper read before the Society four or five years ago. Similar structures were met with in the skin of a dog. In the human axilla they had been described by Sappey, Kölliker, and Frey. These glands were coated by a remarkable layer of plain muscular fibres. The remarkable muscular coating would enable a diagnosis to be made between them and sebaceous glands when an opportunity for anatomical examination of such lumps arrived. Dr. Champney was inclined to accept Dr. Creighton's view of the origin of these lumps." He then added that "these lumps *were not perceptible before delivery*, swelled after parturition, and again slowly decreased in size; in these features and in yielding a secretion of milk they differed altogether from lipomata."

If Dr. Champney is correct in this deduction from his thirty cases, then in the case I have reported, we probably have a lipoma combined with a Champney "axillary lump," made up of specially developed cutaneous glands peculiar to the axilla. If so, then, we shall have a lipomata left when the breasts become inactive, and an opportunity for anatomical examination. If not, then Champney's generalization must be corrected, since the lump in the case of Mrs. S., appeared at least three and a half months before delivery.

DR. SINCLAIR had seen two cases similar to those reported. The breasts were enormously developed, and swellings appeared in each axilla. These swellings were oblong in shape, the size of a Bartlett pear: they never secreted anything so far as he could see. One woman had borne several children and these swellings appeared after every labor. In one case a slight swelling occurred at the menstrual period. She had always regarded these tumors as supernumerary mammæ. They could not be emptied, and were very tender at first. The breasts, in one case, measured eighteen inches across.

DR. REYNOLDS asked if supernumerary glands were not situated below the mammæ and in pairs.

DR. BROWN had seen it stated that these glands were either just below the mammæ or on the abdomen.

DR. BAKER had read of a child, three years of age, who had a nipple in the clavicular region; but there was no sign of a gland.

DR. J. T. G. NICHOLS, present by invitation, reported the following case:

INDUCED LABOR AT THE EIGHTH MONTH ON ACCOUNT OF PELVIC DEFORMITY.

Mrs. B., thirty-seven years of age. First labor, September 18, 1882. Conjugate diameter rather less than four inches. The sacral promontory was prominent and on the horizontal ramus of the left pubes near the symphysis was an exostasis as large as a horse-chestnut. Forceps were used without success, and labor was terminated by craniotomy and subsequent version. The child, a male, weighed twelve pounds. The mother recovered well. She was advised to have labor induced prematurely should she again become pregnant.

In January, 1884, she aborted at about three months. She became pregnant for the third time in March, 1884, menstruation ceasing on the 20th.

November 29th, at 9, P.M., a large elastic bougie was passed into the uterus to the depth of seven inches. There was no hæmorrhage. The head of the fœtus presented. She had a severe cough and the bougie was found outside the uterus on the morning of the 30th. There had been no pains, but the os was softer and there was a slight discharge of dark-brown mucus. The bougie was replaced and kept in place by a cotton plug. On the 1st of December the bougie having been retained in its place, there had been a few slight and irregular pains in the back and thighs. At 4.30, P.M., the vagina was moist, the bloody mucus increased in quantity, the os soft, admitting two fingers easily. The patient was etherized and the os fully dilated by the hand in about forty minutes. The membranes were so firm that I was able to reach a foot without rupturing them, turning the child "as in a bucket of water," as Gooch expresses it, and delivering it without delay. The child, a female, weighed seven and one-half pounds. Both mother and child did well. The child is now, at two years of age, an unusually strong and healthy specimen.

November 3d, 1885, menstruation ceased. July 11th, at 3, P.M., a bougie was passed into the uterus. July 12th, at 3, P.M., there had been no pains of any strength or regularity. The os was soft, admitting two fingers, lubricated with bloody mucus, the head of the child presenting. The patient was etherized and the os dilated by the hand with the greatest facility, the whole process of dilatation and delivery by version occupying less than ten minutes. The child, a boy, weighed eight and a half pounds, and got on very well. The mother recovered without an untoward symptom. At the present time the child is as strong as one born at full term.

Though the use of a bougie failed to bring on efficient labor pains, yet it seemed to be of service by its action upon the os uteri, as shown by the quite abundant secretion of mucus thoroughly tinged with blood,

and by the ease with which manual dilatation was accomplished. I should resort to its use in any case which did not call for immediate action.

The PRESIDENT said he had never found it necessary to use a bougie to prepare the cervix for manual dilatation, and never failed to accomplish dilatation with the fingers alone. The parts yield at intervals of from six to ten minutes, and from one to four hours would be ample time to open the cervix sufficiently to perform podalic version.

DR. REYNOLDS, while agreeing with the President as to the ease of manual dilatation in most instances, had seen cases in which the greatest difficulty was experienced. He queried whether venesection might not be advisable in cases of obstinate cervices.

DR. INGALLS thought that steel dilators should never be used to dilate a firm cervix, as they were liable to do harm: the fingers are much the best instruments.

DR. HOSMER recalled attention to a case[1] he had reported to the Society in June, in which he had been unable to dilate the cervix, and the patient, an eclamptic, died undelivered. He had never failed in this procedure before, and wished to cite his case as showing that digitable dilatation is not always so easy as is generally supposed.

DR. GREEN had seen two cases in which digital dilatation was extremely difficult. In one case, seen recently, he was obliged to deliver at the sixth month, on account of severe hæmorrhage from placenta prævia marginalis. The cervix would admit only one finger and had a hard cartilaginous feel: it was impossible to introduce a second finger far enough to be of any use, and after two hours of fruitless effort (there was no hæmorrhage at the time of operation) a Barnes' bag was used and by its means sufficient dilatation accomplished to make the use of two fingers possible. The cervix soon yielded thereto, and the uterus was emptied. While, therefore, he believed digital dilatation to be easily accomplished as a rule, there were certainly occasional exceptions.

A NEW PORTABLE CASE FOR GYNÆCOLOGICAL INSTRUMENTS.

DR. BAKER exhibited a convenient bag he had devised for containing gynæcological instruments. The bag opened down to the bottom like a valise: there was ample space for a case of bottles, for cotton tampons, pessaries, etc., and the instruments were conveniently and compactly disposed in the sides and flaps.

SPECIMEN OF ADHERENT PLACENTA.

DR. DRIVER, a guest, showed a placenta which had been adherent and was removed with the fingers: it was very thin in part, and in part very thick.

NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED meeting, November 15, 1886.

DR. T. GAILLARD THOMAS read a paper on

LAPAROTOMY AS A DIAGNOSTIC RESOURCE.

During the last century, he said, medicine had been slowly but steadily rising from the lower level of the arts and gradually assuming its place among the sciences. Abstract opinions had become worthless, and facts capable of demonstration to our senses ruled the hour, and controlled professional thought. As this salutary change had developed, every observer must have been struck by the fact that one of its chief factors, and at the same time, to a certain degree, one of its direct results, had been the great development of the art of diagnosis accomplished by the subordination of theoretical methods of exploration and investigation to those which were purely physical.

Throughout the whole domain of surgery, there was no field in which diagnosis was more surrounded by difficulties than that of abdominal neoplasms. This was due to three facts; *first*, the superposition of the intestines; *second*, the great thickness to which the abdominal walls commonly attained; and, *third*, the accumulation of gases in the intestines, which increased all the pre-existing difficulties of exploration. Formerly, the diagnosis of abdominal tumors was allowed to rest upon deductions capable of being drawn from rational and physical methods, the latter of which were limited by the abdominal walls without and the pelvic roof within; but to-day, surgeons devoting themselves to this department of our art were fully agreed as to the propriety of opening the abdominal walls for the purpose of exploring the viscera fully by touch, and to a limited extent by sight.

It seemed to him that no more important era had of late years marked the advance of abdominal surgery, than the general recognition of the fact that when doubt exists as to the diagnosis of abdominal neoplasms or the significance of certain pathological conditions within the peritoneum, the question should be settled by explorative incision. Of the propriety of this practice there could be no possible doubt. After an experience yielded by seven or eight hundred cases, approximately, of laparotomy for various causes, extending over a period of twenty-three years, he felt sure that he could say with entire truth that he had never once regretted opening the abdomen, and that he had in a dozen cases, at least, deeply regretted having failed to do so. He thought it was certain that in the future explorative abdominal incision would become the rule in all cases of the following conditions which did not yield to medical means, and concerning the etiology of which there was great doubt; (1) wounds and injuries of the abdominal viscera; (2) intestinal obstructions; (3) the presence of stones in the gall-bladder or kidneys; (4) the accumulation of blood, pus or serous fluid from any cause; (5) the existence of a neoplasm in any part of the abdomen; (6) the occurrence of serious organic changes in certain of the viscera of the abdomen, such as the kidneys, the spleen, the uterus, the Fallopian tubes or the ovaries; (7) ectopic gestation.

Even under the most favorable circumstances, the most skilful diagnostician was constantly liable to make errors without its aid; and hence it was that explorative incision was peculiarly valuable. Dr. Thomas said he knew of no way in which he could better convey his views and give his experience upon this subject than by mentioning first, some cases in which he had to regret non-interference, and then relating others in which more active measures had produced happier results.

CASE I. About seventeen years ago, he was called in consultation to see a strong, healthy coachman, about twenty-five years of age, who had been suddenly seized with obstruction of the bowels, which had re-

[1] See Vol. CXV, No. 17, page 403 of this Journal.

sisted all medical means and was evidently going to result fatally. The question of laparotomy was carefully canvassed, and it was unfortunately decided not to perform it. The patient died, and on a post-mortem examination a loop of intestine was found constricted by a string of false membrane, the result probably of some long past peritonitis. This was apparent as soon as the abdomen was opened. It was the sole cause of the obstruction, and could at once have been overcome by the snip of a pair of scissors. At that time, however, laparotomy, had it failed, would have met with universal condemnation, and, said Dr. Thomas, "we probably lacked the moral courage to meet the issue, and let the poor fellow die, hoping against hope for a relief which became less and less likely to occur with every hour that elapsed."

CASE II, was that of a patient seen fifteen years ago in consultation with Dr. Otis, who suffered from a uterine fibroid which had grown to such a size that it filled the whole abdomen, and pressed so much upon the viscera under the diaphragm that it was evident that the patient would soon be exhausted unless the tumor was removed. The question of extirpation was carefully considered, and the decision left to Dr. Thomas. At that time the operation was very rarely performed, and still more rarely was it successful. He decided against operation, and the patient died. Upon autopsy a tumor weighing forty pounds was found entirely unattached in the peritoneal cavity and connected with the uterus by a pedicle not larger than two fingers placed side by side. Removal, therefore, would have been easy, and recovery probable; but influenced by the spirit of the times which frowned upon the removal of a large solid tumor of the abdomen, he hesitated to perform the operation. Here an exploratory incision would have made its practicability quite evident.

CASE III. In the early part of his experience as an ovariotomist, a lady suffering from a very large abdominal tumor called upon him with the statement that she had consulted the three most eminent operators living in this country at that time, that they had all agreed that the tumor was a solid one connected with the uterus; and that they all advised against operation. Dr. Thomas agreed with the opinions already expressed, and the patient went home. In about a year she died, and the autopsy showed that the neoplasm was a multilocular ovarian tumor, entirely free from adhesions, with a small pedicle, and which could have been removed with every prospect of success. The reasons for the obscurity of the diagnosis were the following: The tumor was composed of innumerable small cysts, the walls of which were thick and the fluid within them colloid.

CASE IV was another one of intestinal obstruction, occurring in a young Irishman, in which it was decided not to operate, and at the autopsy the following curious condition was found: the transverse colon at its middle was distended with hardened fæcal matter held in one indissoluble mass by a quantity of hay such as is fed to horses, which penetrated it in every way. It was certain that upon abdominal section this would have been readily discovered, and it was probable that by a process of kneading it could have been dislodged and pressed onwards towards the rectum. Dr. Thomas was never able to learn what had induced the man to swallow the hay.

CASE V was one which proved to be extra-uterine pregnancy. There were five physicians in consultation and the vote stood two in favor of exploratory laparotomy, and three opposed to it; Dr. Thomas being one of the two who advocated the procedure. The patient died, and upon post-mortem examination, a three months fœtus was found in the Fallopian tube at its fibriated extremity. The amniotic sac was unbroken, but a slight rent had occurred in the muscular covering of the sac which had opened an artery of sufficient size to cause death by hæmorrhage in the three days which elapsed between the inception of the accident and the fatal result.

Having remarked that he could mention still a number of other similar cases, did time permit, Dr. Thomas said that in his own defence, he would remind his hearers that almost all of this variety of his cases occurred fifteen or twenty years ago, and that this number of years, so rapid had been the recent advance of abdominal surgery, carried us back into the ancient history of the subject. Few such cases occurred to him now, for the very reason that he was a strong advocate for explorative incision as a diagnostic resource. He then proceeded to narrate a few out of the very large number of cases in his later experience, which illustrated the brilliant results which commonly attend upon this procedure.

CASE I. A patient was brought to him for abdominal dropsy, for which tapping had been repeatedly practised, and in whose pelvic cavity a solid tumor, the size of the adult head, could be distinctly felt. This was regarded as a large uterine fibroid, the presence of which had induced ascites, and the removal of which was regarded as entirely impracticable, on account of the weak and exhausted condition to which the patient had become reduced. Dr. Thomas proposed explorative incision, agreeing with the relatives that he would be governed by the light this shed upon the case as to his subsequent action. As soon as his hand passed into the abdomen, he found that the fluid was not the result of ascites, but was ovarian fluid, which poured forth from a ruptured ovarian cyst, which, in its collapsed state, now occupied the pelvic cavity, giving rise to the belief that it was a fibroid. The operation for the removal of the sac was an exceedingly simple one, and the patient made a rapid recovery.

The second case was one of hæmato-salpinx, in which the excessive distension of the Fallopian tubes gave rise to a sensation of solidity, which made the diagnosis before operation very obscure. Both tubes and their corresponding ovaries were removed, and the patient was entirely cured.

The third case was quoted as illustrating the fact that cases of abdominal tumor are sometimes utterly beyond the realm of diagnosis until the cavity is opened. For years this patient had had a firm tumor behind the uterus, when suddenly she became almost collapsed, and suffered greatly from pain in the tumor, which nearly doubled in size in a day or two. Laparotomy was performed, and a large blood-cyst was emptied from the distended pouch of Douglas, and he shelled out the skull of a fœtus of probably six months of intra-uterine life. The patient died ten days after the operation from cardiac thrombosis.

The fourth case was one of intestinal obstruction, caused, as was found on opening the abdomen, by a mass of malignant growth encircling a considerable portion of the large intestine. The patient died about a month after the operation.

There was one class of cases which, in his hands, Dr. Thomas said explorative incision had yielded particularly brilliant results, namely, cases of ascites in the female; and he directed a considerable portion of the paper to the discussion of this subject. He enumerated the causes of ascites as to frequency in the following order: (1) organic diseases of the liver; (2) chronic peritonitis; (3) tubercular peritonitis; (4) malarial spanæmia accompanying great splenic enlargement; (5) the existence of neoplasms within the peritoneal cavity; (6) the prolonged existence of excessive fæcal impaction. Some might doubt the last of these causes, but he had personal experience with it, which had perfectly convinced him of its etiological significance. Later, he went on to make the special point that some cases of excessive ascites, which, by repeated tappings, prove fatal, are due to insignificant uterine or ovarian tumors, which are too small for recognition unless specially and carefully looked for, and the removal of which relieves the fluid accumulation, which, by its exhausting influence, destroys life. These tumors were sometimes no larger than small apples, and could not be recognized, except by the careful examination of an expert. In stout women, or even in those that are thin, they could not be discovered after accumulation of ascitic fluid, even by a master in diagnosis. And, as he had had sufficient evidence in his experience, in some cases, even when a tumor in the pelvis as large as a cocoanut co-existed with the ascites, no connection between the two pathological conditions, as cause and effect, were ordinarily traced by the medical attendant. Should this be the case; should the existence of the neoplasm not be detected, or should the malign influence not be appreciated, even when its presence had been diagnosticated, the physician would probably endeavor to cause absorption by pressing into action the three emunctories of the body. This usually failed, and if it did not, the cause of the symptom remaining after the symptom itself had been removed, frequently repeated resort had to be had to the plan, which, in time, impaired nutrition and exhausted the vital energies.

If, on the other hand, tapping or aspiration were employed, the beginning of the end soon showed itself, and it became merely a question of time how long the system of the patient would bear the exhausting drain to which it was exposed. Dr. Thomas said he had met with a number of cases in which he had succeeded in completely curing aggravated cases of ascites, after tapping had been repeatedly resorted to, and after all hope of recovery had been given up. A few of these were as follows:

Case I. A lady from Connecticut had been repeatedly tapped for ascites, and was rapidly growing weaker from the drain upon her system. After each tapping, a round, hard tumor, about as large as the head of a five-year old child, could be readily detected in the pelvis, and this could also be obscurely felt, even when the dropsical effusion ceased. He opened the abdomen as an explorative procedure, and, finding a fibroid attached to the fundus uteri, removed it, with the effect of perfectly curing the patient.

Case II. A lady from Canada came to him with ascites, which was accompanied by the presence of a solid tumor over one ovary, as large as a cocoanut. She had been tapped once. He removed a solid tumor of the left ovary, and she entirely recovered, having now remained free from dropsy for two years.

Case III. About a year ago, a patient was sent to him suffering from ascites, in whom he could detect by vaginal touch what seemed to be a pelvic neoplasm. He made an explorative incision, found a tumor in Douglas's cul-de-sac, no larger than an apple, and removed it. It was found to be of a sarcomatous nature. The patient recovered from the operation and from the abdominal dropsy, but her physician in Connecticut had recently written to say that a hard tumor could now again be felt in the pelvis, and that ascites was beginning again to show itself. Dr. Thomas thought it highly probable that without removal of the malignant growth, the case would long ago have ended fatally.

Case IV was a counterpart of No. III, except that the post-uterine tumor was a benign fibroid, attached by a rather slender pedicle to the posterior wall of the uterus. It was very difficult — indeed, impossible — to say why, in a certain small number of cases, these tumors created ascites, while they so often occupied the peritoneal cavity for years without causing any such trouble whatever.

Case V. Some years ago he saw in consultation a lady who suffered from severe enteralgia which was caused by the presence of an ovarian cyst as large as the adult head, which was perfectly movable in the abdominal cavity. Fourteen years afterwards dropsy was caused by the nomadic tendencies of the growth, and the patient suffered much distress. Laparotomy was performed, and a monocyst of the ovary with the longest pedicle that he ever saw was removed. In connection with this case Dr. Thomas said that he had removed one ovarian tumor which had lasted twenty-four years, another which had lasted sixteen years, and another which had lasted nine years.

In view of the experience of these and similar cases he said that he felt justified in assuming the position that in cases of ascites in the female, before the patient was relegated to the usual practice of repeated tapping with its universally bad results as to cure, the most thorough investigation as to the possible existence of small neoplasms as important pathological factors should be made, and if signs of their existence were obtained, explorative incision should be practised as a "forlorn hope" that relief might be obtained.

There were but two points connected with exploratory incision which he wished to refer to before closing. The first was the singular fact that in certain cases of abdominal incision in which diagnosis alone was practicable, and others in which removal of the tubes and ovaries proved to be impossible, great improvement sometimes resulted to the patient's general and local condition from the explorative effort alone. The second point was the necessity for certain rules which should be observed in the performance of this simple surgical procedure. They are as follows:

(1) Every explorative incision should be made under the strictest antiseptic precautions. As to strict cleanliness, all are agreed; if antiseptics of chemical character are valueless, they at least, in all probability, do no harm. While the question as to their utility is still *sub judice*, give the patient the benefit of the doubt, and employ them.

(2) Always employ an anæsthetic.

(3) Always make an incision which will admit the whole hand; one which will admit two fingers only is hardly warrantable. If possible, let but one man's hand be passed into the abdominal cavity.

(4) Never hurry an explorative incision, but never prolong one unnecessarily. Let discussion as to diagnosis occur after the peritoneum is closed: not while it is open.

DISCUSSION.

DR. JOSEPH D. BRYANT said that the question of exploratory laparotomy was to his mind the most important one at the present time connected with the subject of abdominal surgery. The distinction should invariably be borne in mind between exploratory laparotomy and what he termed laparotomy in its entirety. He believed that exploratory laparotomy was justifiable in all cases in which the diagnosis was doubtful, but with this reservation, that the means should always be at hand for performing the operation in a proper manner as regards antiseptic precautions, hygienic surroundings, etc. Unless the operation was surrounded with proper safe-guards, there was great danger that discredit would be thrown upon it, and that it would be relegated to the low position which it occupied a few years ago.

During the late war, gun-shot wounds of the abdomen, under the expectant plan of treatment, showed, notwithstanding the many discouraging circumstances which attended them, a percentage of from five to seven recoveries. To-day in laparotomy performed in its entirety, (which included a thorough examination of the abdominal cavity and its contents, the suturing of the wounded intestines, the thorough cleansing of the cavity, and the closure of the wound), there was found to be a percentage of recoveries of no less than sixteen, a gain of more than half. These figures included not only the reported cases, but a considerable number which had come to his personal knowledge, but which had never been publicly placed on record. In the cases actually reported there were nearly twenty-five per cent. of recoveries.

DR. E. G. JANEWAY said that the part of the paper which particularly interested him was that which referred to certain diseases of the abdominal cavity. The question of laparotomy in medical cases was all the time coming more and more prominently before the profession. In peritonitis, however, the conditions were usually so unfavorable that it was impossible that the exploratory operation would be attended with very brilliant results. He said he became so impressed with the unfortunate results attending purely medical treatment in many cases of peritonitis, that in a case last spring he resolved to give the patient the benefit of the best surgical advice, and called Drs. W. T. Bull and Bryant in consultation. It was one in which there was no hope of recovery whatever, unless from operative procedure; and as this offered a possible chance (though the prospect was not by any means encouraging), it was resolved to perform laparotomy. This was accordingly done, but the patient unfortunately lived but for twelve hours afterward; the autopsy showing a perforation of the vermiform appendix. Still, he believed that the operation was justifiable, and he should recommend the same again in any case where the diagnosis could be made sufficiently early.

There was always more or less uncertainty, however, about the diagnosis in such cases, as was well illustrated in that of a physician which had come to his notice. This gentleman had already had attacks of what was apparently well-marked perityphilitis, when there was great pain and tenderness in the right iliac fossa; accompanied by a temperature of 104 lasting a week or ten days. Last, he had another such attack while in Boston, and laparotomy was performed there. Curiously enough, however, the exploration of the abdominal cavity revealed the fact that there was no assignable cause to be found for the trouble; though all the special symptoms regarded as characteristic of perityphilitis were present. Fortunately, the case terminated favorably, and now, at the end of five days after the operation, the patient was doing well.

In many cases of perforation of the intestines in typhoid fever he would be inclined to recommend the trial of laparotomy, if the condition were recognized (especially by the presence of hepatic resonance) sufficiently early; and one case of this kind with a favorable result had already been reported in Germany.

DR. IRA B. READ presented the specimens from a case of

RUPTURE OF AN ANEURISM OF THE THORACIC AORTA,

as a sequel to a paper read before the Association several months ago. The case then reported was one of double popliteal aneurism where both femoral arteries were successfully ligated, the one in June, 1882, and the other in February, 1883. It was consequently more than three and a half years since the last operation, and more than four years since the first. The patient while pursuing his usual avocations died suddenly on the afternoon of October 29th, and at the autopsy made the following day the pericardium was found filled with blood. On opening it the heart was found to be completely imbedded in a large clot of blood, and further search showed that there was a rupture of the ascending portion of the aorta, the orifice in the sac easily admitting the finger. There was, however, but little dilatation observed, and other parts of the aorta showed marked atheromatous degenerations; so that rupture would soon have occurred in some of these had not the point of rupture described proved the weakest.

DR. READ also exhibited a section of the femoral artery above and below the point of ligation. Below, the artery was occluded by what seemed to be an organized fibrous growth, while above, there was the ordinary appearance of the normal artery. Unfortunately, he said, he had never been able to examine the patient for abnormal heart-sounds or aneurismal bruits since the last operation; but at that time there were no physical signs of aortic aneurism.

He had not been able to find any probable cause for the arterial condition which existed in this case. The patient being a young man of thirty, apparently in full vigor, with no history of syphilis, either recent or remote, and not intemperate, he could only accept the fact that there was an atheromatous condition of the arteries which predisposed to aneurism and finally led to his death. The heart was normal in size, and the lungs and liver healthy in appearance; but the spleen and kidneys were very much enlarged.

DR. JANEWAY presented a specimen of

PERFORATION OF THE INTESTINE IN A CASE OF TYPHOID FEVER.

Peritonitis was present for two and a half days before death, but the usual features of the liver on percussion was not replaced by resonance sufficiently early to permit any possible hope from a resort to exploratory laparotomy. The gas in such cases sometimes escaped very slowly, and the difficulty in regard

to the operation was that, unless the liver flatness was lost and there was severe pain, we could not feel assured that peritonitis was present. Indeed, in all cases there was some degree of uncertainty, since instances of supposed perforation and peritonitis had been known to recover. In reality, however, they were cases of retinitis or of gastritis. Such cases, therefore, should make us hesitate to perform laparotomy unless the diagnosis were very clear.

President, DR. C. A. LEALE, presented a specimen of

FAHLBERG'S SACCHARINE.

This is a derivative of coal tar, and is said to be from 1,200 to 5,000 times as sweet as cane sugar. It is comparatively insoluble, and it is not known as yet whether it has any medicinal qualities or not.

Recent Literature.

First Annual Report of the State Board of Health and Vital Statistics of Pennsylvania. Harrisburgh, 1886.

This first report shows that the State Board of Health of Pennsylvania has at once taken its place as an active, efficient organization. The first portion of the report consists of an abstract of its proceedings up to Oct. 1, 1885, together with a catalogue of its library.

The appendices forms the second and larger portion of the report.

Appendix A contains the reports of the Standing Committees, chief among which is the report of the Committee on Water-Supply, Sewerage, and kindred topics. This report is entirely devoted to the subject of the pollution of the Schuylkill River, and contains a carefully compiled table of statistics as to the industries along the banks of the river.

Appendix B deals with the sanitary condition of certain cities, chiefly that of Harrisburg.

Appendix C contains reports on epidemics and sources of disease, and is especially valuable for its very full and minutely detailed account of the epidemic of typhoid fever at Plymouth. The number taken sick was 1,153, deaths 114, and the financial cost of the epidemic estimated at $97,120.25. Reports upon other epidemics of typhoid fever and also of small-pox made up the remainder of this appendix.

Appendix D consists mainly of reports of inspections of local nuisances, and of camp-grounds.

Appendix E contains the quarantine regulations of Philadelphia, and also a description of the disinfecting apparatus employed at the Municipal Hospital in that city. This consists of a fire-proof building containing a furnace with disinfecting chamber (8 by 11 feet) for dry heat, and a fumigating chamber (6 by 11 feet). Another incinerating furnace has been constructed for the destruction of such articles as are worthless, or could not be disinfected by other means. A small fee is charged for disinfection, to those who are able to pay for the process. Great care is taken, in the conveyance of infected articles by a properly constructed vehicle.

The remaining appendices, F and G, contain the regulations of the Board, its circulars, forms, and official correspondence.

The power conferred upon the Board by Section 7 of the Organic Act, making the Board the supervisor of registration is an important one, and if fully exercised will make the State a valuable contributor to the vital statistics of the nation.

Ninth Biennial Report of the State Board of Health of California. Sacramento. 1886.

The efficiency of the State Board was crippled for a season by the loss of three of its members. Its President, Dr. Gibbens, the Secretary, Dr. Hatch, and also Dr. Rowell, the two former by death, and the latter by resignation.

The State Board have endeavored to secure a Registration Law, but without avail. A bill providing for "the analysis of mineral waters, plants, food and drugs, and for the prevention of adulteration" was enacted, but no adequate provision was made for the compensation of the State Analyst authorized by the same act.

The total number of deaths reported to the Board for the year ending June 30, 1885, was 8,238, of which number 4,741 were males and 3,002 were females. The deaths from consumption were 1,227, or a slightly less rate than that of Massachusetts.

The report contains a detailed account of the indigent sick of the State, treated in the County Hospitals. A considerable portion of the report is devoted to climatological discussion, particularly of certain vallies, and of the sea-coast region.

Other papers follow upon Trichinosis, Quarantine, Yellow Fever, and the Influence of Alcohol upon the Human Family. The latter is clearly stated, but in the paragraphs upon the poisonous adulteration of liquors, does not agree with the results obtained by examination made upon the Atlantic coast.

The following statement on page 69, that in "Massachusetts three hundred and ninety-three thousand cases of typhoid fever, with forty thousand deaths, *have been traced* to specific contamination of drinking water," shows an amount of discrimination as to the causes of this disease, which even the most enthusiastic sanitarian would hardly have dreamed to exist.

The Private Treatment of the Insane as Single Patients. By EDWARD EAST, M.R.C.S., L.S.A. London: J. & A. Churchill. 1886. pp. 67.

There is little doubt that insane patients of the wealthy class, might, in many instances, be spared not a little pain, could the practicability of private non-asylum treatment be satisfactorily demonstrated to the general practitioner. The value of Dr. East's *brochure* lies in his successful endeavor to show the desirability of treating singly, certain acute cases of insanity in persons of means, in properly selected quarters away from home. Useful information is given as to the selection of cases. The number both of cases and forms of insanity which are here considered suitable for this kind of care is not excessive when it is remembered that the means for securing a suitable house, and proper attendance and medical supervision are supposed to be always available. The writer says much that is true, and more that is overstated regarding the disastrous influences of asylum surroundings. The disadvantages of the method advocated, however few they may be, might also have been weighed with its merits, without injuring the author's cause. As it is, he will hardly be credited with giving dispassionate and impartial advice. The number of the insane of this class, who are treated at home, is large enough to call for precise details for guidance in practice. In the dearth of such information, many of Dr. East's suggestions will be especially welcome.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, DECEMBER 9, 1886.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

RESEARCHES ON SNAKE-POISON.[1]

IT is a pleasure to study the new memoir in which Dr. Mitchell has continued the account of his work on snake venoms. He secured the fortunate collaboration of Professor Reichert, and the coöperation of several institutions and scientific men. The new researches have been executed with so great skill, the results are so important, and the presentation of the whole matter is so excellent that the memoir must at once be ranked a classic, and the many persons, who coöperated with the authors, are doubtless well pleased with the new knowledge they have helped to harvest.

The subject of snake-poisons has manifold interests. The naturalist seeking the possible history of the evolution of such a gift finds suggestiveness in the similarity of the venomous secretion to that of the salivary glands, and in the affinity of the toxic substances to the normal proteid constituents of the blood. The physiologist wonders over the unknown device by which the tissues producing a poison remain in contact with it and yet are unharmed, the puzzle here being really the same as with the stomach, which digests all tissues save its own. The toxicologists are struck by the dissimilarity of the action of this poison from all others, while the pathologists watch with surprise the rapid and remarkable alterations of the tissues as well as the violent functional disturbances produced by minimal doses of the venom. Best of all, the physician hopes from such studies to gain new resources for the relief of suffering.

The memoir, which is published in handsome quarto form by the Smithsonian Institution, is an admirable example of scientific thoroughness and intelligence. The facts are presented without waste of phrases, in a natural sequence. Each assertion is confirmed by a careful statement of the character and number of experiments made, and the direct observations are clearly given as such; the interpretation is always presented separately. The expressions employed are exact, clear, and definite, and scarce a word is said not justified by the data at command. An occasional remissness may be noted, but no slip of consequence. We cite one flaw, which will illustrate the degree of error to be detected here and there. On page 5 the authors say: "nor can the venom of one kind of snake be distinguished with certainty by any physical peculiarity from that of any other, however remote they may be in the scale of being." The sentence implies that the authors know exhaustively all the physical peculiarities of all snakes, which of course they never meant to say. Nothing shows better the degree of merit of a writing than the faults we find in it. An honest use of adjectives designates a fault, such as we have given an example of, as small.

The essay by Dr. Mitchell and Dr. Reichert deserves praise not only for its display of that care and accuracy, which comes from good training and an appreciation of the requirements of scientific research, but also for the quality of thought, which is an ability and not an acquisition by education. We are glad to point to such an excellent essay as an example of American scientific culture. And as we look at the formidable bibliography of their subject given by the authors we are happy to think that there is one more paper, which is not mentioned in the list, but which contains the best of what has yet been done.

The paper may be best described as giving, first, an account of the poisonous globulins and poisonous peptones of the venom from a chemical standpoint; second, an account of the effects upon the living organism of the venom, and of each of its poisonous constituents.

The venoms bear a strong resemblance in some respects to the saliva of other vertebrates. The active principles of the venom are contained in its liquid parts only. The solid constituents are harmless. The venom may be dried and preserved indefinitely in this condition, with but very slight impairment of its toxicity. It will also keep dissolved in glycerine, probably for any length of time. It contains representatives of two classes of proteids, *globulins* and *peptones*, which are the toxic elements. During the intervals of digestion, the poison may be absorbed by the stomach in fatal quantities.

The poison exerts a powerful local effect upon the living tissues, and produces more rapid necrotic changes than any known substance. It causes œdema, swelling, attended with darkening of parts by infiltration of incoagulable blood, breaking down of tissues, putrefaction, and sloughing. It renders the blood incoagulable. When brought in contact with a vascular tissue of a warm-blooded animal, it produces such a change in the capillary bloodvessels that their walls are unable to resist the normal blood-pressure, thus allowing the blood-corpuscles to escape into the tissues. These lesions are, however, not analogous to those of inflammation, since, in the latter process, it is principally the white corpuscles which emigrate from the blood, and the blood is highly coagulable, while here

[1] By Dr. S. Weir Mitchell and Dr. E. T. Reichert. Published by the Smithsonian Institute.

the blood exudes *en masse*, and coagulates with difficulty, if at all. The action upon the red blood-globules is remarkable. These bodies undergo substantial modifications, that is, they lose their bi-concave shape, become spherical and softened, and fuse together into irregular masses, acting like soft, elastic, colloid material. Except as concerns the paralysis of the respiratory centres, the action upon the nervous system is of but little importance. Certain alterations in the blood-pressure and pulse-rate and in the respiratory movements have been determined, but seem to be subsidiary.

Death in venom-poisoning may occur through paralysis of the respiratory centres, paralysis of the heart, hæmorrhages in the medulla, or possibly through the inability of the profoundly-altered red blood-globules to perform their functions. There can be no question, however, that the respiratory centres are the parts of the system most vulnerable to venom, and that death is commonly due to their paralysis.

The fact that the active principles of venom are proteids, and closely related chemically to elements normally existing in the blood, renders almost hopeless the search for a chemical antidote which can prove available after the poison has reached the circulation, since it is obvious that we cannot expect to discover any substance, which, when placed in the blood, will destroy the deadly principles of venom without inducing a similar destruction of vital components in the circulating fluid. The outlook then for an antidote against venom, which may be available after the absorption of the poison, lies clearly in the direction of a physiological antagonist, or, in other words, of a substance which will oppose the actions of venom upon the most vulnerable parts of the system. The activities of venoms are, however, manifested in such diverse ways, and so profoundly and rapidly, that it does not seem probable that we shall ever discover an agent which will be capable, at the same time, of acting efficiently in counteracting all the terrible energies of these poisons.

The best treatment is a prompt application of a local antidote. Of the generally available local antidotes, the most promising are potassic permanganate, ferric chloride, and tincture of iodine.

Travellers among the Bushmen in South Africa report that they are in the habit of using the dried poison-sac of one snake as an antidote to the poisonous effects of the bite of a different species of reptile; and experience has taught them to rely so thoroughly upon the success of such an application that they do not fear the bite of any snake, however poisonous, if provided with such an antidote. The poison-sacs being reduced to powder are rubbed into the bite or into the incisions around it.

Among some tribes of the Bushmen an even greater power as an antidote is attributed to a small saurian called by them "N'auboo." This little lizard is dried and then powdered, and is rubbed into incisions around the bite of the poisonous snake. Whether with man or beast, this application is held in the highest esteem by the natives, and the observations of several travellers tend to confirm the statements of the natives as to the antidotal power of these poison-sacs and lizards.

An investigation of such claims by so competent an authority as Dr. Mitchell would be of interest.

ON THE TREATMENT OF RETRO-DEVIATIONS OF THE UTERUS.

AT the meeting of German Naturalists and Physicians recently held in Berlin, Professor Fraenkel, of Breslau, read a paper on retro-deviations of the uterus, in which he embodied the results of his gynæcological experience with these misplacements, for the past four years, or since the Thomas retroversion pessary has come into vogue in Germany.

Since October, 1882, Fraenkel has treated 5,180 persons suffering from gynæcological affections; of these, 936 or 18.07 per cent., were cases of retro-deviation, that is, 645 retroflexions and 291 retroversions; the latter figure as contrasted with the number of retroflexions, proves, so Fraenkel says, the inaccuracy of Bantock's statement that retroversion is the most frequent form of retro-deviation. Of these 936 cases of retro-deviation, 417 were patients seen in private practice, and 519 were out-door patients, treated at the polyclinic; the latter class belonged to the lower walks of life, were women who for the most part, had undergone frequent pregnancies, were obliged to work hard, and had lacked the proper care during their confinements; these causes, coupled with habitual lack of suitable nourishment and rest, being fruitful in uterine misplacements, and especially retro-deviations.

In forming a judgment as to the frequency and permanence of a cure in these misplacements, Fraenkel was obliged to rely on the 417 cases in private practice, not being able to follow out the results of the treatment of the out-door patients. Of these 417 patients, 123 were cases where the uterus was irreducible, where no mechanical treatment was necessary, or where the patient was subsequently lost sight of; only 294 cases were left for a fair trial of the value of mechanical support.

The first step in the treatment was of course, to rectify the retro-deviation; this Fraenkel was generally able to accomplish with the hand alone, the patient being in the knee-elbow position; in only 23 cases was he obliged to make use of the sound to straighten out the uterus. In 47 cases he was compelled to call in the aid of an anæsthetic. The only pessary which Fraenkel has used for the past four years is the Thomas pessary, which, he thinks, is sure to retain the uterus in its normal position, keeps clean, and may be worn six months or more without being changed. Another advantage of this pessary is that it allows sexual connection as well as conception; it is, moreover, sufficiently flexible, may be moulded into

any shape to fit the pelvis, and renders possible a permanent cure.

It is hardly necessary to say that retroflexion of the uterus entails sterility, absolute or relative. Retroflexion of the gravid uterus demands only an expectant treatment — provided that symptoms dependent on stasis, or compression of the uterus or neighboring viscera do not exist. The gravid uterus in retroflexion often spontaneously straightens itself as that organ rises out of the pelvis; it is not true, however, according to Fraenkel, that pregnancy cures the retro-deviation, which is almost sure to return after the accouchement. To prevent this, he advises in cases liable to this accident, the application of a large Hodge pessary the eighth or ninth day after confinement.

Of the 294 cases which Fraenkel has treated with the Thomas pessary, there are, he says, 24 in which there is no doubt as to an absolute and permanent cure. These patients have been continually under his observation. The average time during which the pessary was worn was a year; the maximum was 2¼ years, the minimum 2¼ and 3 months. He has no doubt that this ratio of 8.1 per cent. of permanently cured will be greatly increased as observations are continued.

"Despite all," says Fraenkel, "it must be confessed that every kind of pessary is an inconvenience. It is for this reason that gynæcologists have sought to cure the retro-deviation by surgical means. Hence it is that in 1884 Alexander Adam proposed his brilliant operation of shortening the round ligaments. According to the statistics of Doleris this operation has now been performed 118 times; in one-fourth of these cases for prolapses, in the other three-fourths for retro-deviation. Of these patients, three died from the operation, fourteen were without result, and in many of them a pessary became again necessary afterwards. The indications for the Alexander-Adam operation are still uncertain; in general they are said to be: the existence of a retroverted or retroflexed uterus, with descent of the ovaries which are tumefied and too sensitive to tolerate a pessary. Obesity and muscular atrophy in aged women render the operation more difficult, the round ligaments being hard to find, and in these cases the operation may be followed by an inguinal hernia.

"The period of observation is still too short to decide as to the definite success of this operation. In some instances, eight to twelve months after the operation, the result was quite satisfactory. From principle, however, we ought to decline the operation, because there have been cases of death, and because we ought not to hazard the lives of our patients to cure an affection which in no way menaces their existence.

"The failure of the operation depends on the fact that due regard is not had to the causes of the retro-deviation, or the prolapses. Shortening of the round ligaments does not always cause a retro-deviation to disappear, for either these ligaments again relax, or the shortening is such that a permanent pathological anteversion takes place, causing no less trouble to the patient than the previous retroversion.

"Is the descent of the ovaries an indication for the Alexander-Adam operation? I reply in the negative. If the prolapsed ovaries are movable, they may be reduced with the uterus, and are tributary to a mechanical treatment by the pessary; if they are adherent, very sensitive, and if they give rise to reflex neuralgias, it is better to perform castration, and to treat at the same time the retroflexion after the method of Schrœder, by attaching the broad ligament of the uterus (which must be put into a position of anteversion) in the inferior angle of the abdominal wound, and causing it to become adherent thereto. I know of but one indication for the Alexander-Adam operation, namely, grave prolapses, with retroflexion, or laceration of the cervix."

In the discussion which followed the reading of this paper, Kuestner, Hofmeir, Czerny, Viet, Frank, Schwarz, and Martin took part, approving in general of the views of Fraenkel above epitomized.

THE GASTRONOMIC VALUE OF ODORS.

UNDER this head, Mr. Henry T. Finck writes an interesting article in the *Contemporary Review*. Instead of agreeing with Kant that smell "is the least grateful and indispensable of the senses, and that it is not worth while to cultivate it" he affirms "that a better knowledge of the facts compels us to urge that it is of the utmost importance that this sense should be cultivated and its gastronomic function universally recognized." "Were this done," he adds, "the average health and happiness of the community would be increased twenty per cent. or more. For it is no exaggeration to say that not one cook in a hundred knows how to cook, nor one person in a hundred how to eat."

In explaining why cooking and eating are arts in which practice has made few experts, he says that it has not been made sufficiently plain that everything in these arts depends on the sense of smell. He regards the proper object of cookery "to preserve and develop the countless delicious perfumes latent in the raw material of food, or to add others where the food is deficient in natural flavor;" and that the object of rational dining is to enjoy these gastronomic perfumes as intensely and as long as possible, on account of the advantages resulting therefrom to health and happiness."

Mr. Finck repudiates the notion that the indulgence of taste "is an ignoble sense of pleasure," as an echo of mediæval asceticism. The secret of the vitality and vigor of genuine epicures, he says, is because they live on the quintessence of food, which escapes most people. Now such epicures are generally hale and manly fellows, and jovial companions. They enjoy the full fragrance of every morsel they eat, by constantly breathing through their nose. There are two ways in which the efforts to extract all its fragrance from a morsel of food benefits the epicure: (1) To make the sensation one of "linked sweetness long drawn out," it is necessary to keep the morsel in the mouth as long as possible. Now the habit of eating slowly, is of the utmost importance if the organs of digestion are to be kept in a healthy condition. Mr. Finck repeats as probable a suggestion that Mr. Gladstone owes his remarkable physical vigor to certain rules of chewing food which he adopted in 1848, and to which he has adhered ever since: "he laid down as a rule for himself and children that thirty-two bites should be given to each mouthful of meat, and a somewhat less number to bread, fish, etc."

(2) A second and direct advantage resulting from an effort to get at the fragrant odors of food, he thinks, results from the value of these odors, when agreeable, in stimulating the flow of saliva and other alimentary

juices, thus making it sure that the food eaten will be thoroughly utilized in renovating the system. "This stimulating effect of gastronomic odors also explains the French saying that the appetite comes while eating, as well as our habit of reserving sweetmeats, nuts, cheese, etc., for the end of a meal, when rich odors are needed to brace up the flagging appetite. So great and salubrious is the effect of gastronomic odors in stimulating all the glands and functions of the body, that a dinner of savory, fragrant courses may produce in the diner a feeling of warmth and exhilaration, resembling the effects of wine, but with none of the depressing after effects following excessive indulgence in that liquor."

From an olfactory point of view this writer divides agreeable elements into two classes; those which are more fragrant externally, and those which develop superior odors after they are crushed by the teeth or tongue. Strawberries, apples, peaches, have a more refined and flower-like fragrance before they are put in the mouth than after. Cheeses, on the other hand, are not generally regarded as fragrant till they are being eaten. "The odor of Limburger is insupportable to many who, after they have courageously smuggled it past the nasal fortress find it very appetizing and good." The disagreeable external odor is neutralized by the fragrance which is set free as the cheese is crushed in the mouth.

Reference is made to Sir Henry Thompson's book on "Food and Feeding," which speaks of the appetizing odors of fresh meat and vegetables discerned in the national soup of France. He objects to the dried and compressed vegetables so much used at present, because "all the finest qualities of scent and flavor, with some of the fresh juices, are lost in the drying process." In braising, or rational stewing, the meat "becomes impregnated with the odors and flavors of fresh vegetables and sweet herbs." In roasting and broiling, the essential thing is to expose the meat to great heat at the very beginning, so as to coagulate the albumen and prevent the juices and aroma from escaping; then it must be finished under a lower temperature. "Frying, too, which is commonly decried as a barbarous method of cooking, because the dishes are apt to be soaked with unpalatable fat, becomes a valuable culinary method, if the lard is heated to about 400°, for then the object plunged into it is immediately surrounded with a delicious crust, which keeps out the fat, while it keeps *in* the juice and flavor."

In answering the question why dark meats are considered more dainty than white, Mr. Finck replies that it is because the natural aroma is always richer in dark meats. It also explains why the professional gourmand prefers game to poultry, for, in game, all the meat is dark and savory, that is, fragrant, because birds lead a more active life than domestic fowl, which have only dark meat on those limbs that are actively exercised.

In drinking wine, the most important thing, he says, to remember is that its essence, its soul, lies in the perfume or "bouquet." On this bouquet the commercial or gastronomic value of wines depend almost entirely.

Old wines, as a rule, are best, because age mellows their tartness, and intensifies their perfume. "Wine, unlike beer, should always be sipped, and the smaller the quantity taken at a time, the more delicious will be the fragrance."

Mr. Finck's article contains many sound dietetic hints, mixed with a certain amount of amusing gastronomic dilettanteism. If the attainment of remarkable physical vigor by the average American family depends upon the adoption of the rules for mastication attributed to Mr. Gladstone, we fear the digestive millenium for this nation is far removed. The man who counts the "bites" expended upon each article of food is a physiological prig, and there is no surer way of checking the natural functions of a gland than concentrating the mind too closely upon it.

MEDICAL NOTES.

— *Science* makes the somewhat astonishing announcement to its readers of "a new treatment for consumption consisting in the inhalation of *bacteria in the form of spray.*"

— A recent presidential decree in France, says *Science*, regulates the instruction in gymnastics in the *lycées* and colleges for girls. The instruction must be given by female teachers, who must have received a certificate of aptitude from the proper authorities. Such teachers are to receive from 1,200 to 2,000 francs per year each, and may be required to teach sixteen hours a week. They must teach at least twelve hours a week.

BOSTON.

— As an example of enterprise in business, the following clauses from the announcement of a pharmaceutical firm recently established are certainly suggestive: In addition to the ordinary duties of the druggist, it is here proposed to examine the *indications* of the prescription, and to choose a quality of articles in its composition which will or will not (apparently) produce "decided effects."

"Squibb's preparations will be used in all prescriptions where minute accuracy of dose, and decided effects of the remedies are indicated. *Confidential*— Great reduction in price will be made on all prescriptions, but more particularly on those marked P. — poor, and V. P. — very poor. On physician's orders marked "self," for *anything* in our store (to be used by himself and family), *very* low prices will be made."

NEW YORK.

— Dr. Valentine Mott has been making a series of preventive inoculations in the case of two sons and an office-boy of Dr. T. W. Foster, of Yazoo County, Miss., who was bitten by a rabid dog on the third of November. Immediately afterwards Dr. Foster left home with the intention of taking the boys to Paris to be

treated by Pasteur; but learning, on his arrival in New York, that Dr. Mott was provided with proper material for inoculating, which had originally been obtained from Pasteur, he decided to have the treatment carried out here. The process has now been completed, and the children, who suffered no inconvenience from the inoculations, are all in good condition. The young son of Dr. Nowell, of Jersey City, who was bitten by a dog supposed to be rabid, in June last, and afterwards subjected to the Pasteur treatment at the hands of Dr. Mott, continues well up to the present time. In his case the inoculations were discontinued after four had been made, as the boy exhibited certain distressing cardiac and respiratory symptoms for a short time after each inoculation, and his father was unwilling to have the treatment continued any longer.

— It has been ascertained that false-registering lactometers, marked as authorized by the Board of Health, have been sold to certain milk dealers, and a firm on College Place is to be prosecuted by the Board for their manufacture.

— Diphtheria of a fatal type has become increasingly prevalent of late. Among its victims a short time since, were three children of Dr. John Clausnitzen, a German physician living on Bleecker Street, and it is supposed they contracted the disease at the public school which they attended; an inspection by the Health Department revealing the existence of several sanitary defects about the building.

Correspondence.

COLOR-BLINDNESS AMONG APPLICANTS FOR THE NAVY.

BOSTON, 15 Chestnut Street, December 3, 1886.

MR. EDITOR,—The report of the Surgeon-General of the United States Navy states that "of the whole number of persons examined for enlistment during the year, 10,913, 79 were rejected for color-blindness, or feeble color-sense, 7.2+ per 1000 examined." This may be misunderstood, and it supposed that the medical officers of the navy could not detect the *four per cent.* always found among males. I have authority for stating that the seventy-nine were the defective among those only who were tested as to their color-sense. The report does not, unfortunately, say how many these latter were. Many applicants are turned aside at once for other cause, and their vision not examined. Dr. Gunnell, the present Surgeon-General, *now* requires the whole examination to be gone through with in every case, from which we shall have some valuable scientific data.

The report also states that during the last four years, out of 495 applicants for the Naval Academy, *eight* have been rejected on account of defective color-sense. Now all these applicants had been recommended by members of Congress, etc., and supposed to have been examined by some medical man as to their physical fitness, as is usual. This enforces my letter to the JOURNAL of April 29th, 1886, on "Physical Examinations of Candidates for the United States Naval and Military Academies," in which I warn medical gentlemen examining candidates at the request of members of Congress.

Respectfully yours,
B. JOY JEFFRIES, M.D.,

CALCULI. THEIR ALLEGED "SPONTANEOUS" FRACTURE.[1]

BOSTON, December 4, 1886.

MR. EDITOR, — Friable stones are no doubt broken by the contractions of a thickened bladder, much as English walnuts are in the hand. In the Harvard Medical School Museum there was a mass of little calculi from a patient, I think of the late Dr. Gay, which I supposed to have been so comminuted. There may be other causes of "spontaneous fracture," but this is probably a common one.

Very truly yours, H. J. B.

NEW YORK SKIN AND CANCER HOSPITAL.

NEW YORK, December 4, 1886.

MR. EDITOR, — It will interest many of your readers to learn that the New York Skin and Cancer Hospital, 243 East 34th Street, New York, and its country branch at Fordham, Westchester County, N. Y., have been for some time, and are now, ready for the admission of patients from this and other States. Applications may be directed to the undersigned Secretary of the Medical Board.

Yours very respectfully,

A. JACOBI, M.D., *Pres. Med. Board.*
L. D. BULKLEY, M.D., 4 East 37th St., N. Y., *Sec. Med. Board.*

REGULATION OF THE PRACTICE OF MEDICINE.

LEAVENWORTH, Kansas, November 27, 1886.

MR. EDITOR, — Pinon salve is the name of a remedy prepared by Dr. (?) Fowler of this city and his son in Kansas City, Mo., who claim to have derived their medical knowledge and skill from the Indians and from nature. The "*Doctor*" says other physicians don't like to have him practice because he has no "*diplomy*," but he uses only herbs and no minerals, therefore he thinks he is justified in treating patients, and does so, relying mainly on his cure-all "Pinon Salve." Whether there is any necessity for enacting laws and enforcing them to regulate the practice of medicine I leave to your judgment, after reading the following testimony given by the "*Doctor*" and a girl living in the house with one of his patients, named Carrie Carter, before the coroner in an investigation as to the cause of Miss Carter's death. I append the evidence copied verbatim from the coroner's records.

Very truly yours, W. D. BIDWELL, M.D.

Maria Johnson, being sworn, says, "I live here with the deceased and others. She complained about one o'clock on the night of the 23d inst. of cramps all over her body. I gave her red-pepper tea. It had no effect on her. When morning came, I went for Dr. Fowler, and he came at ten o'clock. The deceased was still in pain. He then gave her the half of a dose of morphine he had in a spoon of water, and *in ten minutes* he gave her the other half. Then she went to sleep, and soon waking, she complained of an itching and a hurting in her face. She then fell asleep, and we woke her once. She opened her eyes, and went to sleep again, and died at half-past eight last evening. She was subject to inward pains, and suffered in her limbs from rheumatism. Her breathing was hard and rapid before she died." MARIA JOHNSON.

George Fowler, being sworn, states, "I am a practising physician, and was called on the 24th of this month to see and prescribe for a girl named Carrie Carter, corner of Dakota and Third in this city. On my arrival, I found her suffering from a severe attack of bilious colic. I gave her *five grains of morphine* in two doses, half an hour intervening between the two doses. In my judgment, from the symptoms she manifested she was *struck with death* when I arrived, her under jaw falling down, and her eyes rolling back, leaving nothing but the whites to be seen. Her

[1] See Journal, Dec. 2d.

pulse had moved up towards her elbow, which, in my opinion, is a strong indication of approaching death. I observed the first dose of morphine had no effect in allaying the pain, and in fifteen minutes after taking the second dose, she gradually got into a case of stupor. I then made an examination externally of her abdomen, and found small lumps over the surface of her bowels, and to the best of my opinion, the pain and spasms accrued from these lumps. I then left the house, but returned between two and three o'clock, and found her sleeping, breathing very hard. Next morning I again called, and she was dead. *I do not think five grains of morphine was too much when divided into two parts, half an hour intervening between the doses.* Some time ago I gave her sister, Mrs. Richardson, *six grains of morphine*, and it had the effect of only making her drowsy. I generally buy my medicine at Aller's drug store, and use very little of it."

Attest, GEORGE FOWLER. JOHN C. LYNCH, *Coroner.*

Deaths reported 2,264: under five years of age 827: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 441, lung diseases 303, consumption 200, diphtheria and croup 202, measles 59, diarrhœal diseases 52, typhoid fever 51, malarial fever 31, scarlet fever 20, whooping-cough 10, cerebro-spinal meningitis seven, puerperal fever five, erysipelas four. From typhoid fever, Philadelphia 13, New York 10, Baltimore six, Brooklyn and Boston five each, District of Columbia three, Pittsburgh and Cambridge two each, Charleston, New Bedford, Salem, Taunton and Haverhill one each. From malarial fevers, New York 10, Brooklyn six, New Orleans seven, Philadelphia four, Baltimore, District of Columbia, Nashville and Charleston one each. From scarlet fever, Brooklyn six, New York four, Philadelphia three, Pittsburgh four, Boston two, Baltimore one. From whooping-cough New York and Pittsburgh three each, Brooklyn, Boston, New Orleans and District of Columbia one each. From cerebro-spinal meningitis, New York four, Lowell two, Nashville one. From puerperal fever, Philadelphia two, Brooklyn, Boston and Worcester one each. From erysipelas, New York, Brooklyn, New Orleans and Pittsburgh one each. One case of small-pox reported in Pittsburgh.

In the 19 cities and greater towns of Massachusetts, with a population of 983,791 (population of the State 1,941,465), the total death-rate for the week was 19.03 against 16.64 and 19.33 for the two preceding weeks.

In the 28 greater towns of England and Wales with an estimated population of 9,093,817, for the week ending November 6th, the death-rate was 18 2. Deaths reported 3,172: infants under one year of age 793; acute diseases of the respiratory organs (London) 293, diarrhœa 102, scarlet fever 74, measles 66, fever 52, whooping-cough 42, diphtheria 32.

The death-rates ranged from 11.9 in Derby to 28.0 in Wolverhampton; Birkenhead 14.2; Birmingtom 15.0; Huddersfield 21.2; Hull 17.2; Leeds 23.2; Leicester 16.8; Liverpool 19.8; London 16.7; Manchester 24.5; Nottingham 14.6; Sheffield 20.1; Sunderland 15.6.

In Edinburgh 24.8; Glasgow 24.1; Dublin 26.2.

In the 28 greater towns of England and Wales, with an estimated population of 9,093,817, for the week ending November 13th the death-rate was 19.5. Deaths reported 3,407: infants under one year of age 886; acute diseases of the respiratory organs (London) 321, scarlet fever 91, measles 81, diarrhœa 80, fever 69, diphtheria 36, whooping-cough 44.

The death-rates ranged from 13.9 in Brighton to 30.0 in Oldham; Birmingham 18.1; Bradford 17.4; Hull 20.7; Leeds 21.7; Leicester 17.6; Liverpool 23.8; London 17.9; Manchester 23.8; Nottingham 19.2; Sheffield 17.3.

In Edinburgh 21.1; Glasgow 23.4; Dublin 23.6.

For the week ending November 13th, in the Swiss towns, there were 32 deaths from consumption, lung diseases 16, diarrhœal diseases nine, diphtheria and croup four, measles two, whooping-cough two, puerperal fever two, typhoid fever one.

The death-rates were: at Zurich 9.5; Geneva 21.1; Basle 21.5; Berne 17.7.

The meteorological record for the week ending November 27, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps: —

Week ending Saturday, Nov. 27, 1886.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 27, 1886, TO DECEMBER 3, 1886.

CALDWELL, DANIEL G., major and surgeon. Granted twenty days extension of his leave of absence. S. O. 278, A. G. O., December 1, 1886.

MOSELEY, E. B., captain and assistant surgeon. Relieved from duty as attending surgeon in San Francisco, Cal. S. O. 99, Division of the Pacific, November 19, 1886.

MOSELEY, EDWARD B., captain and assistant surgeon. Directed to take charge of the medical purveying depot, San Francisco, Cal., until the arrival of a proper bonded officer. S. O. 99, Division of the Pacific, November 19, 1886.

TESSON, LOUIS S., captain and assistant surgeon. Granted leave of absence for four months, to date from November 13, 1886. S. O. 278, A. G. O., December 1, 1886.

EGAN, PETER R., first lieutenant and assistant surgeon. Assigned to duty at Fort Clark, Tex. S. O. 162, Department of Texas, November 22, 1886.

WAKEMAN, WM. J., first lieutenant and assistant surgeon. Leave of absence extended three months. S. O. 274, A. G. O., November 26, 1886.

MCCAW, W. D., first lieutenant and assistant surgeon. Granted leave of absence for two months, to take effect when his services can be spared. S. O. 274, A. G. O., November 26, 1886.

ANDERSON, C. L. G., first lieutenant and assistant surgeon. (Recently appointed). Ordered for assignment in Department of Arizona. S. O. 277, A. G. O., November 30, 1886.

BALL, ROBERT R., first lieutenant and assistant surgeon. (Recently appointed.) Ordered for duty in Department of the Missouri. S. O. 278, A. G. O., December 1, 1886.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING DECEMBER 4, 1886.

FARNELL, W. G., surgeon. Detached from the "Kearsarge," proceed home and wait orders.

GATEWOOD, J. D., passed assistant surgeon. Detached from the "Kearsarge," proceed home and wait orders.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDING NOVEMBER 27, 1886.

WILLIAMS, L. L., assistant surgeon. Granted leave of absence for twenty-four days, to take effect when relieved, November 15, 1886.

MCINTOSH, W. P., assistant surgeon. Granted leave of absence for twenty-seven days, November 26, 1886.

NORMAN, SEATON, assistant surgeon. When relieved to rejoin station (New York); granted leave of absence for twenty-three days, November 27, 1886.

APPOINTMENT.

Dr. W. L. Munro, of Providence, has been appointed Surgeon to Out-patients at the Rhode Island Hospital.

SOCIETY NOTICES.

RHODE ISLAND MEDICAL SOCIETY. — A regular quarterly meeting of the Rhode Island Medical Society will be held in Lyceum Hall, 62 Westminster Street Providence, on Thursday, December 16, 1886, at 10 o'clock, A.M. Papers by Drs. W. R. White, F. P. Capron, and C. V. Chapin.

G. D. HERSEY, *Secretary.*

SUFFOLK DISTRICT MEDICAL SOCIETY. OBSTETRIC AND GYNÆCOLOGICAL SECTION. — There will be a meeting of this Section at the large Medical Library Room, 19 Boylston Place, on Wednesday evening, December 15th, at 7.45 o'clock. The meeting will open with a discussion upon a paper read at the last meeting by Dr. E. W. Cushing, entitled, "On Erosions of the Os Uteri, with Demonstrations by Stereoptican of Photographs from Life and Micro-photographs." Drs. R. H. Fitz, W. H. Baker, H. O. Marcy, W. E. Boardman, C. M. Green and J. W. Elliot will take part in the debate. Reader: by invitation, Dr. W. S. Brown, of Stoneham, "The Rôle of the Ovary." Refreshments after the meeting.

JAMES R. CHADWICK, M.D., *Chairman.*
ROBERT B. DIXON, M.D., *Secretary.*

DEATH.

Died, in Boston, December 4, 1886, Frederic Clinton Woodbury, M.D., M.M.S.S., aged twenty-five years.

BOOKS AND PAMPHLETS RECEIVED.

The Physicians' Visiting List. (Lindsay and Blakiston's) for 1887. Thirty-Sixth Year of its Publication.

A Case of Injury from a Strong Electric Current. By Harold N. Mayer, M.D., Assistant to the Chair for Diseases of the Nervous System, Rush College, Chicago. (Reprint.)

A Summary of Tolsti's Views on Arterio-Capillary Sclerosis. By F. B. Stephenson, M.D., United States Navy. New York: 1886. (Reprint.)

La Goutte, Sa Nature et Son Traitement. Par Dr. W. Ebstein. Traduction du Dr. E. Chambard. Introduction du Prof. Charcot, Orné de 12 Chromolithographics. Paris: J. Rothschild. 1887.

Fiske Fund Prize Dissertation, No. XXXVI. New and Altered Forms of Disease, due to the Advances of Civilization in the last Half Century. By Hobart Amory Hare, M.D.B.Sc. Philadelphia: P. Blakiston, Son & Co. 1886.

A Preliminary Report on Electrolysis; with Special Reference to its Trial in Inflammatory Products in the Female Pelvis. By James Hendrie Lloyd, A.M., M.D., Instructor in Electro-Therapeutics in the University of Pennsylvania. Read before the Philadelphia County Medical Society, October 27, 1886. (Reprint.)

Antisepsis in Ovariotomy and Battey's Operation. Seventy Consecutive Cases with Sixty-Eight Recoveries and Two Deaths. By Robert Battey, M.D., Rome, Georgia. Fellow of the American Gynæcological Society, and Fellow of the British Gynæcological Society; Member of the American Medical Association; Ex-President Medical Association of Georgia; Honorary Fellow of the Obstetrical Society of Edinburgh, of the Medical Society of Virginia, of Abingdon Academy of Medicine, of Augusta Medical Society, of Atlanta Society of Medicine, etc. 1886. (Reprint.)

UNITED STATES ARMY MEDICAL DEPARTMENT LIBRARY

Lectures.

SCIENTIFIC MEN AND THEIR DUTIES.[1]

BY JOHN S. BILLINGS, M.D., (HARV.), Surgeon U. S. A.

Mr. Chairman and Fellow Members of the Philosophical Society: — The honor of the presidency of such a society as this — carrying with it, as it does, the duty of giving at the close of the term of office an address on some subject of general interest, has been aptly compared to the little book mentioned in the Revelations of St. John — the little book which was "sweet in the mouth but bitter in the belly." I can only thank you for the honor, and ask your indulgence as to the somewhat discursive remarks which I am about to inflict upon you.

There is a Spanish proverb to the effect that no man can at the same time ring the bell and walk in the procession. For a few moments to-night I am to ring the bell, and being thus out of the procession I can glance for a moment at that part of it which is nearest. At first sight it does not appear to be a very homogeneous or well-ordered parade, for the individual members seem to be scattering in every direction, and even sometimes to be pulling in opposite ways; yet there is, after all, a definite movement of the whole mass in the direction of what we call progress. It is not this general movement that I shall speak of, but rather of the tendencies of individuals or of certain classes; some of the molecular movements, so to speak, which are not only curious and interesting of themselves, but which have an important bearing upon the mass, and some comprehension of which is necessary to a right understanding of the present condition and future prospects of science in this country.

The part of the procession of which I speak is made up of that body or class of men who are known to the public generally as "scientists," "scientific men," or "men of science." As commonly used, all these terms have much the same significance; but there are, nevertheless, shades of distinction between them, and in fact we need several other terms for purposes of classification of the rather heterogeneous mass to which they are applied. The word "scientist" is a coinage of the newspaper reporter, and as ordinarily used, is very comprehensive. Webster defines a scientist as being "one learned in science, a savant" — that is, a wise man — and the word is often used in this sense. But the suggestion which the word conveys to my mind is rather that of one whom the public suppose to be a wise man, whether he is so or not, of one who claims to be scientific. I shall, therefore, use the term "scientist" in the broadest sense, as including scientific men, whether they claim to be such or not, and those who claim to be scientific men whether they are so or not.

By a scientific man I mean a man who uses scientific method in the work to which he specially devotes himself; who possesses scientific knowledge, not in all departments, but in certain special fields. By scientific knowledge we mean knowledge which is definite and which can be accurately expressed. It is true that this can rarely be done completely, so that each proposition shall precisely indicate its own conditions, but this is the ideal at which we aim. There is no man now living who can properly be termed a complete savant, or scientist, in Webster's sense of the word. There are a few men who are not only thoroughly scientific in their own special departments, but are also men possessed of much knowledge upon other subjects and who habitually think scientifically upon most matters to which they give consideration; but these men are the first to admit the incompleteness and superficiality of the knowledge of many subjects which they possess, and to embrace the opportunity which such a society as this affords of meeting with students of other branches and of making that specially advantageous exchange in which each gives and receives, yet retains all that he had at first.

Almost all men suppose that they think scientifically upon all subjects; but, as a matter of fact, the number of persons who are so free from personal equation due to heredity, to early associations, to emotions of various kinds, or to temporary disorder of the digestive or nervous machinery that their mental vision is at all times achromatic and not astigmatic, is very small indeed.

Every educated, healthy man possesses some scientific knowledge, and it is not possible to fix any single test or characteristic which will distinguish the scientific from the unscientific man. There are scientific tailors, bankers and politicians, as well as physicists, chemists, and biologists. Kant's rule, that in each special branch of knowledge the amount of science, properly so called, is equal to the amount of mathematics it contains, corresponds to the definition of pure science as including mathematics and logic, and nothing else. It also corresponds to the distinction which most persons, consciously or unconsciously, make between the so-called physical and the natural or biological sciences. Most of us, I presume, have for the higher mathematics, and for the astronomers and physicists who use them, that profound respect which pertains to comparative ignorance, and to a belief that capacity for the higher branches of abstract analysis is a much rarer mental quality than are those required for the average work of the naturalist. I do not, however, propose to discuss the hierarchy of the sciences; and the term science is now so generally used in the sense of knowledge, more or less accurate, of any subject, more especially in the relations of causes and effects, that we must use the word in this sense, and leave to the future the task of devising terms which will distinguish the sciences, properly so called, from those branches of study and occupation of which the most that can be said is that they have a scientific side. It is a sad thing that words should thus become polarized and spoiled, but there seems to be no way of preventing it.

In a general way we may say that a scientific man exercises the intellectual more than the emotional faculties, and is governed by his reason rather than by his feelings. He should be a man of both general and special culture, who has a little accurate information on many subjects, and much accurate information on some one or two subjects, and who, moreover, is aware of his own ignorance, and is not ashamed to confess it.

We must admit that many persons who are known as scientists do not correspond to this definition. Have you never heard, and perhaps assented to, some such statements as these: "Smith is a scientist, but he does n't seem to have good, common sense," or "he is a scientific crank?"

[1] President's address before the Philosophical Society of Washington, D. C., December 4th, 1886.

The unscientific mind has been defined as one which "is willing to accept and make statements of which it has no clear conception to begin with, and of whose truth it is not assured. It is the state of mind where opinions are given and accepted without ever being subjected to rigid tests." Accepting this definition, and also the implied definition of a scientific mind as being the reverse of this, let us for a moment depart from the beaten track which presidential addresses usually follow, and instead of proceeding at once to eulogize the scientific mind and to recapitulate the wonderful results it has produced, let us consider the unscientific mind a little, not in a spirit of lofty condescension and ill-disguised contempt, but sympathetically, and from the best side that we can find. As this is the kind of mind which most of us share with our neighbors, to a greater or less degree, it may be as well not to take too gloomy a view of it. In the first place, the men with unscientific minds form the immense majority of the human race.

Our associations, habits, customs, laws, occupations, and pleasures are, in the main, suited to these unscientific minds, whose enjoyment of social intercourse, of the every-day occurrences of life, of fiction, of art, poetry, and the drama is, perhaps, none the less because they give and accept opinions without subjecting them to rigid tests. It is because there are a goodly number of men who do this that the sermons of clergymen, the advice of lawyers, and the prescriptions of physicians have a market value. This unscientific public has its uses. We can at least claim that we furnish the materials for the truly scientific mind to work with and upon; it is out of this undifferentiated mass that the scientific mind supposes itself to be developed by specialization, and from it that it obtains the means of its own existence. The man with the unscientific mind, who amuses himself with business enterprises, and who does not care in the least about ohms or pangenesis, may, nevertheless, be a man who does as much good in the world, is as valuable a citizen, and as pleasant a companion as some of the men of scientific minds with whom we are acquainted.

And, in this connection, I venture to express my sympathy for two classes of men who have in all ages been generally condemned and scorned by others, namely, rich men and those who want to be rich. I do not know that they need the sympathy, for our wealthy citizens appear to support with much equanimity the disapprobation with which they are visited by lecturers and writers — a condemnation which seems in all ages to have been bestowed on those who have by those who have not.

So far as those who actually are rich are concerned, we may, I suppose, admit that a few of them — those who furnish the money to endow universities and professorships, to build laboratories, or to furnish in other ways the means of support to scientific men — are not wholly bad. Then, also, it is not always a man's own fault that he is rich; even a scientist may accidentally and against his will become rich.

As to those who are not rich, but who wish to be rich, whose chief desire and object is to make money, either to avoid the necessity for further labor, or to secure their wives and children from want, or for the sake of power and desire to rule, I presume it is unsafe to try to offer any apologies for their existence. But when it is claimed for any class of men, scientists or others, that they do not want these things it is well to remember the remarks made by old Sandy Mackay after he had heard a sermon on universal brotherhood: "And so the deevil's dead. Puir auld Nickie; and him so little appreciated, too. Every gowk laying his sins on auld Nick's back. But I'd no bury him until he began to smell a wee strong like. It's a grewsome thing is premature interment."

I have tried to indicate briefly the sense in which the terms "scientist" and "scientific man" are to be used and understood, and you see it is not an easy matter. The difficulty is less as regards the term "man of science." By this expression we mean a man who belongs to science peculiarly and especially, whose chief object in life is scientific investigation, whose thoughts and hopes and desires are mainly concentrated upon his search for new knowledge, whose thirst for fresh and accurate information is constant and unsatiable. These are the men who have most advanced science, and whom we delight to honor, more especially in these later days, by glowing eulogiums of their zeal, energy, and disinterestedness.

The man of science, as defined by his eulogists, is the *beau idéal* of a philosopher, a man whose life is dedicated to the advancement of knowledge for its own sake, and not for the sake of money or fame, or of professional position or advancement. He undertakes scientific investigations exclusively or mainly because he loves the work itself, and not with any reference to the probable utility of the results. Such men delight in mental effort, or in the observation of natural phenomena, or in experimental work, or in historical research in giving play to their imagination, in framing hypotheses, and then in endeavoring to verify or disapprove them, but always the main incentive is their own personal satisfaction (with which may be mingled some desire for personal fame), and not the pleasure or the good of others. Carried to an extreme, the eulogy of such men and their work is expressed in the toast of the Mathematical Society of England: "Pure mathematics; may it never be of use to any man!" Now, it is one thing to seek one's own pleasure, and quite another thing to pride one's self upon doing so. The men who do their scientific work for the love of it do some of the best work, and, as a rule, do not pride themselves on it, or feel or express contempt for those who seek their pleasure and amusement in other directions. It is only from a certain class of eulogists of pure science, so called, that we get such specimens of scientific "dudeism" as the toast just quoted, opposed to which may be cited the Arab saying that "A wise man without works is like a cloud without water."

There are other men who devote themselves to scientific work, but who prefer to seek information that may be useful; who try to advance our knowledge of Nature's laws in order that man may know how to adapt himself and his surroundings to those laws, and thus be healthier and happier. They make investigations, like the men of pure science — investigations in which they may or may not take pleasure, but which they make, even if tedious and disagreeable, for the sake or solving some problem of practical importance. These are the men who receive from the public the most honor, for it is seen that their work benefits others. After all, this is not peculiar to the votaries of science. In all countries and all times, and among all sorts and conditions of men, it has always

been agreed that the best life, that which most deserves praise, is that which is devoted to the helping others, which is unselfish, not stained by envy or jealousy, and which has as its main pleasure and spring of action the desire of making other lives more pleasant, of bringing light into the dark places, of helping humanity.

But, on the other hand, the man who makes a profession of doing this, and who makes a living by so doing, the professional philanthropist, whether he be scientist or emotionalist, is by no means to be judged by his own assertions. Some wise German long ago remarked that "*Esel singen schlecht, weil sie zu hoch anstimmen*" — that is, "asses sing badly because they pitch their voices too high," and it is a criticism which it is well to bear in mind.

In one of the sermons of Kin O's[2] the preacher tells the story of a powerful clam who laughed at the fears of other fish, saying that when he shut himself up he felt no anxiety; but on trying this method on one occasion, when he opened his shell he found himself in a fishmonger's shop. And to rely on one's own talents, on the services one may have rendered, on cleverness, judgment, strength, or official position, and to feel secure in these, is to court the fate of the clam.

There are not very many men of science, and there are no satisfactory means of increasing the number; it is just as useless to exhort men to love science, or to sneer at them because they do not, as it is to advise them to be six feet three inches high, or to condemn a man because his hair is not red.

While the ideal man of science must have a "clear, cold, keen intellect, as inevitable and as merciless in its conclusions as a logic engine," it would seem that, in the opinion of some, his greatness and superiority consists not so much in the amount of knowledge he possesses, or in what he does with it, as in the intensity and purity of his desire for knowledge.

This so-called thirst for knowledge must be closely analogous to an instinctive desire for exercise of an organ or faculty, such as that which leads a rat to gnaw, or a man of fine physique to delight in exercise. Such instincts should not be neglected. If the rat does not gnaw, his teeth will become inconvenient or injurious to himself, but it is not clear that he deserves any special eulogium merely because he gnaws.

It will be observed that the definition of a scientific man or man of science, says nothing about his manners or morals. We may infer that a man devoted to science would have neither time nor inclination for dissipation or vice; that he would be virtuous either because of being passionless, or because of his clear foresight of the consequences of yielding to temptation.

My own experience, however, would indicate that this inference is not correct, or that some supposed scientific men have been wrongly classified as such. How far the possession of a scientific mind and of scientific knowledge compensates, or atones for, ill-breeding or immorality, for surliness, vanity, and petty jealousy, for neglect of wife or children, for uncleanliness, physical and mental, is a question which can only be answered in each individual case; but the mere fact that a man desires knowledge for its own sake appears to me to have little to do with such questions. I would prefer to know whether the man's knowledge and work is of any use to his fellow-men, whether he is the cause of some happiness in others which would not exist without him. And it may be noted that while utility is of small account in the eyes of some eulogists of the man of science, they almost invariably base their claims for his honor and support upon his usefulness.

The precise limit beyond which a scientist should not make money has not yet been precisely determined, but in this vicinity there are some reasons for thinking that the maximum limit is about $5,000 per annum. If there are any members of the Philosophical Society of Washington who are making more than this, or who, as the result of careful and scientific introspection, discover in themselves the dawning of a desire to make more than this, they may console themselves with the reflection that the precise ethics and etiquette which should govern their action under such painful circumstances have not yet been formulated. The more they demonstrate their indifference to mere pecuniary considerations, the more creditable it is to them; so much all are agreed upon; but this is nothing new, nor is it specially applicable to scientists. Yet while each may and must settle such questions as himself for himself, let him be very cautious and chary about trying to settle them for other people. Denunciations of other men engaged in scientific pursuits, on the ground that their motives are not the proper ones, are often based on insufficient or inaccurate knowledge, and seldom, I think, do good.

This is a country and an age of hurry, and there seems to be a desire to rush scientific work, as well as other things. One might suppose, from some of the literature on the subject, that the great object is to make discoveries as fast as possible; to get all the mathematical problems worked out; all the chemical combinations made; all the insects and plants properly labelled; all the bones and muscles of every animal figured and described. From the point of view of the man of science, there does not seem to be occasion for such haste. Suppose that every living thing were known, figured, and described. Would the naturalist be any happier? Those who wish to make use of the results of scientific investigation, of course, desire to hasten the work, and when they furnish the means, we cannot object to their urgency; moreover, there is certainly no occasion to fear that our stock of that peculiar form of bliss known as ignorance will be soon materially diminished.

From my individual point of view, one of the prominent features in the scientific procession is that part of it which is connected with Government work. Our Society brings together a large number of scientific men connected with the various Departments, some of them original investigators; most of them men whose chief, though not only pleasure is study. A few of them have important administrative duties, and are brought into close relations with the heads of Departments and with Congress. Upon men in such positions a double demand is made, and they are subject to criticism from two very different standpoints. On the one hand are the scientists, calling for investigations which shall increase knowledge, without special reference to utility, and sometimes asking that employment be given to a particular scientist, on the ground that the work to which he wishes to devote himself is of no known use, and, therefore, will not support him. On the other hand, is the demand from the business men's point of view — that they shall show practical results; that in demands for appropriations from the public

[2] Cornhill Magazine, August, 1869, p. 196.

funds, they shall demonstrate that the use to be made of such appropriations is for the public good, and that their accounts shall show that the money has been properly expended — "properly," not merely in the sense of usefully, but also in the legal sense — in the sense which was meant by Congress in granting the funds. Nay, more, they must consider not only the intentions of Congress, but the opinions of the accounting officers of the Treasury, the comptroller and auditor, and their clerks, and not rely solely on their own interpretation of the statutes, if they would work to the best advantage, and not have life made a perpetual burden and vexation of spirit.

There is a tendency on the part of business men and lawyers to the belief that scientific men are not good organizers or administrators, and should be kept in leading-strings; that it is unwise to trust them with the expenditure of, or the accounting for, money, and that the precise direction in which they are to investigate should be pointed out to them. In other words, that they should be made problem-solving machines as far as possible. When we reflect on the number of persons, who, like Mark Twain's cat, feel that they are "nearly lightning on superintending"; on the desire for power and authority, which is almost universal, the tendency to this opinion is not to be wondered at. Moreover, as regards the man of science, there is some reason for it in the very terms by which he is defined, the characteristics for which he is chiefly eulogized.

The typical man of science is, in fact, in many cases an abnormity, just as a great poet, a great painter, or a great musician is apt to be, and this not only in an unusual development of one part of the brain, but in an inferior development in others. True, there are exceptions to this rule — great and illustrious exceptions; but I think we must admit that the man of science often lacks tact, and is indifferent to, and careless about matters which do not concern his special work, and especially about matters of accounts and pecuniary details. If such a man is at the head of a bureau, whose work requires many subordinates, and the disbursement of large sums of money, he may consider the business management of his office as a nuisance, and delegate as much of it as possible to some subordinate official, who, after a time, becomes the real head and director of the bureau. Evil results have, however, been very rare, and the recognition of the possibility of their occurrence is by no means an admission that they are a necessity, and still less of the proposition that administrative officers should not be scientific men.

I feel very sure that there are always available scientific men, thoroughly well informed in their several departments, who are also thoroughly good business men, and are as well qualified for administrative work as any. When such men are really wanted, they can always be found, and, as a matter of fact, a goodly number of them have been found, and are now in the Government service.

The head of a bureau has great responsibilities; and while his position is, in many respects, a desirable one, it would not be eagerly sought for by most scientific men if its duties were fully understood.

In the first place the bureau chief must give up a great part of his time to routine hack work. During his business, or office, hours he can do little else than this routine work, partly because of its amount, and partly because of the frequent interruptions to which he is subjected. His visitors are of all kinds and come from all sorts of motives — some to pass away half an hour, some to get information, some seeking office.

It will not work well if he takes the ground that his time is too important to be wasted on casual callers and refers them to some assistant. In the second place he must, to a great extent at least, give up the pleasure of personal investigation of questions that specially interest him, and turn them over to others. It rarely happens that he can carry out his own plans in his own way, and perhaps it is well that this should be the case. The general character of his work is usually determined for him either by his predecessors, or by Congress, or by the general consensus of opinion of scientific men interested in the particular subject or subjects to which it relates. This last has very properly much weight; in fact, it has much more weight than one might suppose, if he judged from some criticisms made upon the work of some of our bureaus whose work is more or less scientific. In these criticisms it is urged that the work has not been properly planned and correlated; that it should not be left within the power of one man to say what should be done; that the plans for work should be prepared by disinterested scientific men — as, for instance, by a committee of the National Academy — and that the function of the bureau official should be executive only.

I have seen a good deal of this kind of literature within the last ten or twelve years, and some of the authors of it are very distinguished men in scientific work; yet I venture to question the wisdom of such suggestions. As a rule, the plans for any extended scientific work to be undertaken by a Government department are the result of very extended consultation with specialists, and meet with the approval of the majority of them. Were it otherwise, the difficulties in obtaining regular annual appropriations for such work would be great and cumulative, for in a short time the disapproval of the majority of the scientific public would make itself felt in Congress. It is true that the *vis inertiæ* of an established bureau is very great. The heads of Departments change with each new administration, but the heads of bureaus remain; and if an unfit man succeeds in obtaining one of these positions, it is a matter of great difficulty to displace him; but it seems to me to be wiser to direct the main effort to getting right men in right places rather than to attempt to elaborate a system which shall give good results with inferior men as the executive agents, which attempt is a waste of energy.

You are all familiar with the results of the inquiry which has been made by a Congressional committee into the organization and work of certain bureaus which are especially connected with scientific interests, and with the different opinions which this inquiry has brought out from scientific men. I think that the conclusion of the majority of the committee, that the work is, on the whole, being well done, and that the people are getting the worth of their money, is generally assented to. True, some mistakes have been made, some force has been wasted, some officials have not given satisfaction; but is it probable that any other system would give so much better results that it is wise to run the risk of change?

This question brings us to the only definite proposition which has been made in this direction, namely,

the proposed Department of Science, to which all the bureaus whose work is mainly scientific, such as the Coast Survey, the Geological Survey, the Signal Service, the Naval Observatory, etc., shall be transferred.

The arguments in favor of this are familiar to you, and, as regards one or two of the bureaus, it is probable that the proposed change would effect an improvement; but as to the desirability of centralization and consolidation of scientific interests and scientific work into one department under a single head, I confess that I have serious doubts.

One of the strongest arguments in favor of such consolidation that I have seen, is the address of the late president of the Chemical Society of Washington, Professor Clarke, "On the Relations of the Government to Chemistry," delivered about a year ago. Professor Clarke advises the creation of a large, completely-equipped laboratory, planned by chemists and managed by chemists, in which all the chemical researches required by any department of the Government shall be made, and the abandonment of individual laboratories in the several bureaus on the ground that these last are small, imperfectly equipped, and not properly specialized; that each chemist in them has too broad a range of duty and receives too small a salary to command the best professional ability. He would have a national laboratory, in which one specialist shall deal only with metals, another with food products, a third with drugs, etc., while over the whole, directing and correlating their work, shall preside the ideal chemist, the all-round man, recognized as the leader of the chemists of the United States. And so should the country get better and cheaper results. It is an enticing plan and one which might be extended to many other fields of work. Granting the premises that we shall have the best possible equipment, with the best possible man at the head of it, and a sufficient corps of trained specialists, each of whom will contentedly do his own work as directed and be satisfied, so that there shall be no jealousies, or strikes, or boycotting, and we have made a long stride toward Utopia. But before we centralize in this way we must settle the question of classification. Just as in arranging a large library there are many books which belong in several different sections, so it is in applied science. Is it certain that the examination of food-products or of drugs, should be made under the direction of the national chemist rather than under that of the departments which are most interested in the composition and quality of these articles? This does not seem to be a self-evident proposition by any means. The opinion of a scientific man as to whether the Government should or should not undertake to carry out any particular branch of scientific research and publish the results, whether it should attempt to do such work through officers of the Army and Navy, or more or less exclusively through persons specially employed for the purpose, whether the scientific work shall be done under the direction of those who wish to use, and care only for, the practical results, or whether the scientific man shall himself be the administrative head and direct the manner in which his results shall be applied; the opinion of a scientific man on such points, I say, will differ according to the part he expects or desires to take in the work, according to the nature of the work, according to whether he is an Army or Navy officer or not, according to whether he takes more pleasure in scientific investigations than in administrative problems, and so forth.

It is necessary, therefore, to apply a correction for personal equation to each individual set of opinions before its true weight and value can be estimated, and, unfortunately, no general formula for this purpose has yet been worked out.

I can only indicate my own opinions, which are those of an Army officer, who has all he wants to do, who does not covet any of his neighbors' work or goods, and who does not care to have any more masters than those which he is at present trying to serve. You see that I give you some of the data for the formula by which you are to correct my statements, but this is all I can do.

I am not inclined at present to urge the creation of a department of science as an independent department of the Government having at its head a Cabinet officer. Whether such an organization may become expedient in the future seems to me doubtful; but at all events I think the time has not yet come for it.

(To be continued.)

ON THE HYGIENIC LAWS AND SANITARY CONDITIONS OF ANCIENT ROME.[1]

BY PROF. RODOLFO LANCIANI, LL.D.,
Government Director of Archæological Researches at Rome.

The hospital, even in its most rudimentary shape, was not known in Rome much before the third century of the Christian Era. In fact, Celsus Aurelianus, an eminent physician, who wrote at the beginning of the third century a treatise "On Acute and Chronic Diseases" — "*De Morbis Acutis et Chronicis*" — reproaches his colleagues for their obstinacy in keeping the patients in absolute confinement, as a practice injurious to the progress of science. It is not difficult to explain this state of things. First, the members of the higher classes of society were not in need of public sanitary institutions; secondly, the slaves, of whom the manufacturing and trading class was mostly composed, had to be assisted at the expense of their own masters in case of sickness; and besides, medicine was not known and practised as a science, but only on an empiric sort of routine. Hence the consequence that patients were compelled to confide more in gods than in men, and trust in a supernatural help to get rid of their ailments. We must also bear in mind that charity was a feeling altogether unknown in ancient times, and suffocated, at any rate, by the spirit of conquest, by the maintenance of slavery, and by the passion for bloody and revolting gladiatorial shows, which rendered even the most tender Roman hearts and souls insensible to the sufferings of the neighbor.

Livy asserts (I, 12) that the Romans kept always faithful to the precept of Numa: "*unam opem ægris corporibus relictam si pax veniaque ab diis impetrata esset*" — that the peace and good-will of gods were the only remedies and means to recuperate the lost health. Thus the more common cases of sickness to which mankind is subject were deified and idolized, and temples and shrines were set up in their honor. I have mentioned above the altars of the Fever, the sacred wood of Mephitis, the shrine of Orbona, and so on. Apollo, as a God of Hygiene, had a temple near the theatre of Marcellus. This temple, built in the

[1] Concluded from page 541.

year 321 of Rome, and opened for public worship two years later, on the occasion of a terrific stroke of pestilence, has been re-discovered quite by accident nine years ago, in the cellar of a third-class inn, near the Piazza Montanara, called the Albergo della Catena. It will be excavated, we hope, in 1887, in consequence of the destruction of the neighboring ghetto; and considering its state of remarkable preservation, we trust we shall be able to find, at least, fragments of the famous group by Praxiteles and Scopas, representing Apollo fulminating Niobe and her sons, a group described by Pliny (xxxv., 5, 28). Next in importance to the temple of Apollo was the temple of Health, the site of which corresponds nearly to that of the Barberini Palace, on the northern slope of the Quirinal. Women laboring in child-birth could apply to not less than thirteen goddesses, beginning from Juno Lucina, down to Deverra, Diana, Alemona, Nona, Decima, Partula, Antevorta, Postvorta, Eugeria, Fluonia Uterina, Intercidona, etc.

In the year 459, Rome being in danger of annihilation by another plague, followed, as Livy says, by a stupendous mortality, the Sybilline books were consulted, as they always were in cases of supreme danger. The answer was: "*Æsculapium ab Epidauro Romæ arcessendum*" (x., 32) — Æsculapius must be removed from Epidaurus to Rome — and so they did. The new god was comfortably and neatly installed in an island on the Tiber, now called the island of S. Bartolomeo, and its temple became the greatest sanitary establishment in the metropolis.

The practice followed by Roman lower classes was this: "Patients in danger of life were brought into the perystile or atrium of the sanctuary and put to sleep there, evidently by means of narcotic drugs, in order that Æsculapius could manifest in their dreams the proper way of healing their troubles. Once the recipe obtained, the priests themselves would undertake the cure of the guests; and if the cure succeeded, by some unforeseen and wonderful coincidence, then an *ex-voto* was suspended in the sacristy of the sanctuary, together with a tablet describing the happy event. Here is the text of one, given by Thomassinus: "In this last day, said the oracle to Caius the Blind: come to the sacred altar and kneel in front of it, then touch it on the left-hand side, and apply instantly the hand to the eye. Having obeyed, he recovered at once the eyesight, amidst the applause of the assembled multitudes." Is it not a striking coincidence, is it not a striking proof of the vitality of tradition in Rome, the fact that the very same island of the Tiber, the very same spot on the island should have always been since Roman times, and should be now, the seat of a hospital, the hospital of S. John Calibitas? Another curious anecdote is this: It seems that at the entrance of the Fabrician Bridge, leading from the Campus Martius into the island, there were shops for the sale of *ex votos* of every description, exactly as they are to be seen now on the approaches to the great sanctuaries of the Catholic countries. One of these shops has been discovered only six months ago, in the foundations of the left embankment of the Tiber. It contained a large number of anatomical specimens in painted terra-cotta, magnificently modelled from nature, and representing heads, ears, eyes, breasts, arms, hands, knees, legs, feet — *ex-votos* to be offered by happy mothers, etc. The most interesting pieces are three life-size human trunks, cut open right across, and showing the whole anatomical apparatus of the various organs and intestines, such as the lungs, liver, heart, bowels, etc. These pieces have not yet been examined by experts, and, consequently, I am not able to say whether they are capable of throwing any light on ancient hygienic and anatomical matters.

You must not suppose that men of education would resort to such absurdities as those I have described in connection with the temple of Æsculapius. Cicero has strongly condemned the practice in his book, "De Divinitate," but the populace, in spite of such good advice, would adhere to its ignorance and superstition, and this obstinacy had then, and has still, such a firm hold, and such deep roots in the Italian lowest classes, that, only one year ago, in September, 1885, when the cholera broke out in Sicily, physicians trying to exercise their mission of charity were stabbed and killed by the dying patients, as they are stabbed and killed in Hungary and Croatia.

Another strange practice, imported from the East into Rome, was the exposure of the sick in the streets and under open porticos, in order that passers-by could give them advice from personal experience. The first physicians in Rome, if such name can be given to men knowing only the use of a few herbs and potions, came from Abruzzi and from the shores of the lake of Fucino. In progress of time, patrician families secured, at a high price, the services of slaves, experts in medicine, to whom the office of a modern "*valet de chambre*" was assigned. These slaves, emancipated after long, successful services, would open shops, called sometimes *Medicinæ*, sometimes *Farmacopolæ*, in which drugs and physics were sold, and surgical operations performed. For these operations, the patient was put into anæsthesia in a much surer way than we do now with chloroform or laughing-gas. A successful physician was sure to receive high official distinctions. Arcagathus, a Peloponnesian who migrated to Rome in 219, not only was rewarded with the citizenship, but obtained a residence, with shop and office, bought at public expense. Asclepias, from Drusa, Bythinia, was almost deified by the populace, and held in great estimation by Crassus and Cicero. Julius Cæsar was the first statesman to promote the welfare of hygienists, by recognizing them as professors of a liberal art, with rights to citizenship. Augustus, having been cured by his freedman, Antonius Musa, from a dangerous illness, by means of fomentations and cold compresses, made him a knight, honored him with a bronze statue in the temple of Æsculapius, and exempted forever his colleagues from any kind of income-tax. Nero organized the service by naming an archiater, or superintendent of court-physicians. Schools of medicine were opened, and students organized themselves in a corporation, the seat of which was on the Esquiline. When one of the professors was called to visit a patient, he was followed by the whole body of pupils, because, there being no hospitals at the time, this was the only way they could learn and gain experience. Martial describes one of these professional visits in the ninth epigram of the fifth book, and relates how, having sent for Dr. Symmachus, he came at once to his bed, accompanied by more than one hundred disciples, who, one by one, felt his pulse with hands almost frozen by the northern wind, or tramontana, which happened to be blowing at the time.

The merit of having organized a service of public assistance, in the true modern and philanthropic sense of the word, belongs to Antoninus Pius, who acted, I am sure, under the indirect pressure of Christian influence and charity, the new faith having made immense progress in Rome under his wise, temperate rule.

The new sanitary codex comprised the institution of head-physicians (archiaters) in every inhabited centre, and a set of rules for the medical service in the largest cities of the empire. These medical officers had to be elected by the town council, and to be approved by the patres-familiæ. In progress of time, the election had further to be sanctioned by the College of Physicians practising in the same town, and even by the Emperor himself. The assistance to the poor was compulsory and gratuitous.

Such are the results of the campaign thus engaged in by the Romans against malaria, and fought with the means I have endeavored to describe, one by one.

Original Article.

A CASE OF GASTROTOMY. DIGITAL EXPLORATION OF ŒSOPHAGUS, AND REMOVAL OF PLATE OF TEETH. RECOVERY.[1]

Remarks upon the Operation, and Observations upon the Anatomy of the Œsophagus.

BY MAURICE H. RICHARDSON, M.D.,
Surgeon to Massachusetts General Hospital, Demonstrator of Anatomy, Harvard Medical School.

Many cases have been recorded where foreign bodies have become lodged in the œsophagus. The most common seat of impaction or lodgement is the very beginning of the tube, at the level of the cricoid cartilage, where its calibre is less than at any other point. It is at or just above this point that smooth and rounded bodies become checked in their course. When their diameter exceeds that of the distended œsophagus they are either regurgitated or produce death by impediment to the air-passages. If a smooth body once passes the first constriction of the œsophagus, it meets no further resistance until the opening in the diaphragm is reached. This is usually passed because the diameter at this part is greater than at the first constriction. When, however, the body is angular, irregular, or with sharp points it is much more likely to become impacted at these natural constrictions, though it may become arrested at any part in the tube, its sharp points catching in the mucous membrane.

The symptoms which follow the impaction of a foreign body in the œsophagus, may be very slight, so that little attention will be paid to them by the patient. We may observe pain, dysphagia, suffocation, spasms, alterations in the voice, cough, expectoration, deformity, or none of these may be present.[2] The immediate symptoms depend upon the shape and size of the body. Pieces of meat may be large enough to produce suffocation, and this is not uncommon in old people who have lost their teeth. Immediate pains may be caused by laceration of the walls of the œsophagus by sharp points or by the pressure of a large body. It may be said that the immediate symptoms are not severe and rarely cause death. Subsequently we may have inflammatory conditions, ulcerations, hæmorrhage, starvation or tolerance of the foreign body.

The inflammatory changes which may follow are œsophagitis or periœsophagitis with formation of abscess. The body may become detached in this way. The abscess may break into the œsophagus or outwardly, or into a neighboring organ. Ulceration may extend into the trachea and bronchi or it may erode a bloodvessel and cause death by fatal hæmorrhage, or by asphyxia. The pleura or pericardium may also be perforated. Death rarely follows primarily, but is generally due to the secondary changes mentioned. A foreign body lodged in the œsophagus, when natural efforts have failed to dislodge it, must either be extracted, pushed down into the stomach or cut out, or it must be left to itself and palliative measures adopted.

Œsophagotomy is to be resorted to only after all other means have failed. Up to the present year this method has been the last and only resort, and it has afforded relief only in those cases where impacted bodies have been within reach from the external incision in the neck.

The possibility of reaching the œsophagus from below has been alluded to by several writers, and œsophageal strictures have been treated instrumentally after the stomach has been opened for purposes of alimentation. Prof. Loreta, of Bologna, in a monograph published in 1884[3] mentions cases of gastrotomy not only for digital dilatation of the pylorus but also for divulsion of œsophageal stricture. He gives four cases with recovery in which a small opening was made in the stomach, instruments passed into the œsophagus, and the stricture divulsed. The operation was completed by sewing up both stomach and abdominal wound. Bergmann and Schattauer have succeeded in passing bougies through a stricture of the œsophagus from below. Wentlechner has passed a delicate sound down through the stricture and out of the opening in the stomach. He also attached a thread to the lower end of the sound and by means of it drew up after it larger instruments, drainage-tubes, etc.[4] Von Hacker[5] did a similar operation and obtained a good result in a cicatricial contraction of the œsophagus by the introduction of a Nélaton catheter stretched over a whalebone guide. In a letter to Dr. Randolph Winslow, of Baltimore, he mentioned two cases in which the operation of dilatation by the use of drainage tubes attached to filiform bougies had been performed, in one of which he states that the operation had already been successful, and the other had been but recently performed at the time of writing.[6]

In these cases advantage has been taken of the gastric fistula already existing to approach the œsophagus from below, or a small incision has been made into the stomach for the introduction of bougies or divulsors of small diameter.

I can find no recorded cases where the œsophagus has been explored with the fingers, the hand being introduced into the stomach.

The experience gained in the following case with an experimental study of the anatomy of the parts concerned, convinces me that this surgical procedure

may be undertaken in many cases where operative measures have hitherto been considered out of the question. In twelve subjects I found the distance in a straight line from the centre of an incision five inches long, one inch below and parallel to the margin of the ribs on the left side, beginning at the outer border of the rectus abdominis to the œsophageal opening in the diaphragm, to be 7.55 inches. Through an incision of five inches in the anterior wall of the stomach the hand and forearm could easily be passed and the index and middle finger introduced through the diaphragmatic opening their whole length, about two and a half inches. There was some difficulty at first in finding the cardiac opening, but this was very soon overcome.

The best method of introducing an instrument into the œsophagus is as follows: The cut in the stomach should be made at the point which presents itself most naturally at the centre of the abdominal incision, that is, about four inches from the pylorus. The assistant makes tense the lesser curvature by traction with the thumb and finger downwards, forwards and to the left. The lesser curvature is thus straightened out and the mucous surface of the stomach corresponding to it is formed into a sort of groove, along which the instrument glides directly into the cardiac orifice. To do this easily one must accustom himself to the operation by repeated experiments upon the cadaver. Great assistance can be gained by finding the diaphragmatic opening outside the œsophagus, with the left hand. I was able in this way repeatedly to grasp coins placed in the œsophagus beyond reach of the fingers by means of forceps. In cases of foreign bodies the œsophagus should be examined before the stomach is opened, for it may be possible thus to dislodge them. A small incision should then be made into the stomach through which efforts may be made to remove the body by means of instruments. Later this may be enlarged enough to admit the hand. It is important to ascertain as accurately as possible the position of the foreign body with reference to the opening in the diaphragm, not only that we may be sure it is within reach of the finger from below, but also that we may know its relations with other organs.

At the diaphragm the œsophagus is not in contact with the pleura, and it is not so closely related to the aorta behind. A foreign body impacted here would not be in such close relations with important structures, and the danger from ulceration and perforation would be less. This fact would have weight in deciding upon a palliative course of treatment. Moreover, an abscess at this point would most naturally drain into the stomach. Two inches higher up, the œsophagus is directly in contact with the heart in front, the aorta behind, and the pleural cavities on each side.

The danger of erosion of arteries, perforation of the pleura and pericardium, abscess of the mediastinum, etc., would be very much greater than at the diaphragm and we might not feel ourselves justified in waiting. Finally, it may be demonstrated that the body is beyond the reach of the finger and the surgeon will then be called upon to decide whether it is better to open the stomach for the purpose of using instruments of traction, or to attack from above by œsophagotomy.

The following table gives the measurements of the distance from the upper incisors, when the head is fully extended, to the opening in the diaphragm, as well as the measurements referred to above.

No.	Height. Ft.	In.	From Incisors. In.	From Abdominal Cut. In.
1	6		14½	
2	4	3 (deformed).	10½	Not Taken. " "
3	5	4	15	8½
4	5	7½	16½	7½
5	5	6	15¾	8¼
6	5	3¾	15	7
7	5	4	15¼	6¾
8	5	7	15½	7½
9	5	5½	15½	7½
10	5	6	16½	8½
11	5	7	16¾	8
12	5	4	15½	7
13	4	10	15½	7½
14	5	4	14	8¼
Average	5	5	15	7.55

From these figures it may fairly be said that a foreign body may be reached with the finger from below, when its distance from the incision, determined by the probang, in not less than thirteen inches. In a cadaver in which this measurement was fifteen and three-quarters inches, I was able to touch, grasp, and remove with my fingers a silver quarter-dollar situated twelve and one-half inches from the incisors. This was repeated several times with larger coins, silver half-dollars and dollars.

A glance at this table will show that the distance from the incisors to the diaphragm does not bear a constant ratio to the height. A man of six feet measured fourteen inches, while another of four feet ten inches, measured fifteen and one-half. Without regarding the height we may say that the average distance is about fifteen inches in fourteen subjects taken at random.

Since reading this paper and hearing Dr. Cheever's remarks in regard to the distance he could reach down the œsophagus in his cases of œsophagotomy, I have dissected with special reference to this point. I find that in a female subject with a measurement of fifteen and three-fourths inches from incisors to diaphragm, not only can the aorta be reached easily after left œsophagotomy in neck, but the finger can be hooked under the arch. When the left index was in contact with the lower disc of a silver dollar in the œsophagus, the right middle finger introduced from above through the neck, could very easily be made to touch the upper. It was next found practicable to pass a half-dollar from one hand to the other, and finally the *fingers* were made to touch each other. In four other subjects these experiments were repeated and the fingers could be brought in contact with ease.

From these observations I think it may be asserted that *there is no part of the human œsophagus which may not be reached, or very nearly reached, with the finger either by gastrotomy or by œsophagotomy.* Also that with the finger as a guide instruments may be used with intelligence upon any part of the canal.

The following unique case illustrates clinically the truth of some of the anatomical observations recorded above. It should be said, however, that these facts were not known at the time of the operation, and it was not thought to be at all certain that the foreign body was within reach of the fingers. Preparations were made beforehand for the use of a long forceps both for crushing and for tractions, and it was even thought that the lithotrite might be necessary. The case illustrates also the remarkable tolerance of the œsophagus at times. As will be seen, a grave

complication already existed without giving any sign of its presence, namely, a pericœsophageal abscess which the manipulations of the operation caused to break into the lung. The other symptoms present, pain and starvation, in themselves rendered the operation imperative. The facts made known by the operation and subsequent history prove that if a much earlier attempt at removal had been made, the danger of inflammation and starvation would have been avoided and the chance of recovery from the operation itself would have been better.

John McCarty, thirty-seven years of age, six feet one and one-half inches high, very robust, teamster, came to the medical room of the Out-Patient Department of the Massachusetts General Hospital, September 26th, 1886. He was referred to me as out-patient surgeon. He said that three days before, while eating he had swallowed his false teeth. He described the plate as being about the size of a silver half-dollar carrying the four anterior teeth of the left upper jaw, and as leaving two small hooks by which it was fastened to the teeth still left in that bone. I passed a small ivory probang into the œsophagus and detected the foreign body easily. It was situated far down in the tube apparently near the stomach. He was recommended for admission and was assigned to Dr. Beach.

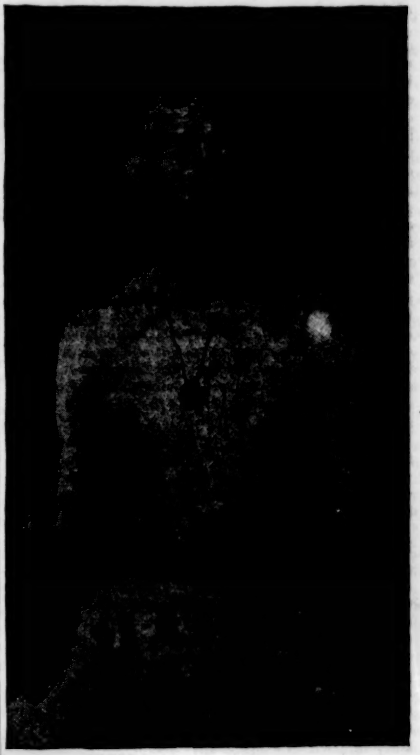
On entrance he felt weak and complained of pain under the sternum between the nipples. There was also a little soreness on pressure. Had some pain in taking a long breath. Swallowed liquid food. Two days later felt better; was examined by Dr. Beach. An ivory-tipped probang struck against a hard body apparently just above the cardiac opening of the stomach. A good-sized stomach-tube passed by the teeth. A coin probang was caught under the plate. On pulling, the end broke off.

September 29. Consultation of surgeons decided against operation.

October 3d. One week after accident was able to take soft food well.

October 7th. Passed end of probang *per rectum.*

October 23d. Had some pain and soreness apparently at the pylorus. Some nausea. A stomach-tube was passed into the stomach without obstruction. Was given charpie cut fine mixed with white of egg.[7]



November 10th. Was improving in health and strength. Had good appetite and less pain.

Discharged, to report if he has any trouble.

December 3d. Reported that he felt comfortable; had not passed teeth.[8]

Patient re-entered hospital July 23d, 1886. Says he has been losing flesh since leaving the hospital, and now weighs one hundred and thirteen pounds, about sixty-five pounds less than before accident. He has considerable soreness when he swallows, and at times is unable to retain any food. He is very much emaciated, though his health is good.[9]

I examined again with the ivory probang, and found a foreign body exactly in the same spot as the year before. His condition at this time was quite deplorable. From a robust and strong man, whose normal weight was one hundred and eighty pounds, he had become extremely emaciated. It was with great difficulty that he could swallow enough liquid food to keep alive. Solid food could not be taken at all. He complained of constant and severe pain in the epigastrium, and in the back. From the date of entrance until August 5th he was carefully observed. It was found that the probang came in contact with the foreign body just fourteen inches from the incisor teeth. As nearly as could be estimated, this would make their position about two inches above the line of the nipples (see Fig.), and some little distance

From a photograph taken 3 months after operation. The plate is suspended on the chest wall to show as accurately as possible its location when lodged in the œsophagus. The distance from the plate to the centre of the abdominal incision is 12 inches. As the stomach was drawn out of the abdominal wound two or three inches the distance from the opening in the stomach to the foreign body was at least 12 inches.

above the cardiac opening of the stomach. In this position, the plate, with its sharp edges, would lie between the heart in front, and the thoracic aorta behind, and separated on either side from the pleura by the thickness of the œsophageal wall.

After careful consideration of the case, I advised that an attempt be made to remove the plate by opening the stomach. The patient gladly consented. For two days before the operation nothing was

[7] See Poulet, Vol. 1, p. 158. Case in which the irregularities of a plate of teeth, lodged in stomach, were covered and concealed after a diet of oakum and raisins continued one week. Expulsion from rectum with oakum adherent and irregularities thereby smoothed.

[8] Mass. Gen. Hosp. Records, Vol. 219, p. 200.

[9] Mass. Gen. Hosp. Records, Vol. 226, p. 80.

taken into the stomach, except water and stimulants, food being given entirely by enemata. It was not practicable to wash out the stomach, because of the difficulty in passing a stomach-tube by the obstruction.

August 5th, 1886. Patient was carefully etherized. An unsuccessful attempt was first made to demonstrate beyond possibility of a doubt the presence of the foreign body. Some difficulty presented itself in doing this, and the attempt was abandoned to save time. Moreover, it was not essential, as the probang had been used the day before in studying the location of the plate.

An incision about six inches long was made one and one-half inches below and parallel to the margin of the ribs in the left hypochondrium. It began at the outer border of the *rectus abdominis*, three inches from tip of ensiform cartilage, and extended outwards and downwards. The abdominal wall was rapidly cut, layer by layer, until, all bleeding having been stopped, the peritoneal cavity was opened. The abdominal opening was held up by means of a T-hook at each extremity. The stomach was found lying empty in its usual position. An external examination was made of the cardiac orifice and of the whole stomach, to see if the foreign body might not be found and dislodged by manipulations. Nothing could be detected either in the stomach or the diaphragmatic opening. The stomach was now drawn out of the abdominal wound as far as possible, and placed upon a carbolized towel, and in this position all the subsequent manipulations were done. A small incision about one and one-half inches long was first made through the anterior wall of the stomach, beginning near the pylorus, and extending upwards and backwards midway between the greater and lesser curvatures. The walls were very thick and vascular. After cutting through the peritoneal and muscular layer, a dense network of large and tortuous vessels came into view, which, on being divided, bled very profusely. This was controlled by smooth-bladed, hæmostatic forceps.

After two unsuccessful attempts to introduce grasping instruments into the œsophagus through this small opening, I enlarged the incision sufficiently to admit my hand and forearm. The stomach was first wiped out with sponges and held with T-hooks. The walls of the diaphragmatic opening were found with some difficulty after passing the hand seemingly a very great distance. The middle and index fingers were then pushed up the œsophagus between the heart in front and aorta behind until the plate was felt, with the teeth pointing downwards, apparently embedded in a mass of soft granulations. The hand was withdrawn, and long-bladed forceps introduced into the œsophagus, guided by the index finger, but attempts to grasp the plate were unsuccessful. I then re-introduced my hand, and by careful manipulation with the index finger, succeeded in detaching the left extremity of the plate from its bed in the left side of the canal. The other extremity was then loosened from the right side, and the plate passed easily into my fingers, and was withdrawn from the stomach.

The mucous membrane was united with a continuous silk suture, to control the hæmorrhage which followed the removal of the hæmostatic forceps. The peritoneal surface was closed with thirty-six fine, silk sutures, after the method of Lembert, placed three-sixteenths of an inch apart, the line of union being most perfect and beautiful. The stomach was then dropped back into the abdominal cavity, and the external wound closed in the usual manner with interrupted deep and superficial silk sutures. Iodoform and gauze dressings were applied, with compression. Time of operation, one hour and a quarter.

Although very little blood escaped, the peritoneal cavity was carefully sponged out. "At the end of the operation the patient's pulse was full and strong. At 3 P. M., was having much pain in his side, and was very restless. He complained of cold, and his extremities were chilly to touch. Given brandy freely by rectum. At 5.30, much more comfortable and warm; pulse good. Washes mouth with water, but does not swallow it. Has enema of milk, ℥iss, and brandy, ℥ss, every two hours." During the afternoon vomited a small amount of blood. Evening temperature, 98°.

August 6th. Very comfortable; given ℥i of water.

August 7th. In the morning quite comfortable, except for a slight cough. In the afternoon, he had severe fits of coughing, and after much exertion and distress, would raise ℥i to ℥ii of thick, tenacious pus. Raised during day about ℥viii. Temperature 101.8°.

August 8th. Much better. Raises ℥ii to ℥iv of pus in twenty-four hours. Began to take whiskey and water by mouth, a teaspoonful every ten minutes. Fed by rectum at frequent intervals. Temperature 99.2°.

August 11th. Stitches removed; wound firmly united.

August 13th. Milk by mouth, ℥ss every one-half hour. Some suppuration of stitch-holes, which were enlarged and dressed with a Phenyle pad.

August 14th. ℥ii milk, broth, or ice cream every hour. Ale at intervals. Expectoration much less, and cough not so troublesome.

August 19th. Scraped beef, with cracker for dinner.

August 21st. Given solid food in quite large quantities. No pain; scarcely any cough or expectoration. Wound healed.

August 24th. Sits up in bed.

August 27th. Lungs examined by Dr. E. N. Whittier. Dulness, with broncho-vesicular respiration and broncophony at base of right lung, which accounts for slight elevation of temperature.

September 2d. Walks about ward. 4th. Out in wheel-chair.

September 5th. Weighs one hundred and twenty-one pounds. No cough; signs in lungs disappearing.

September 12th. Weight, one hundred and twenty-seven and a half pounds.

September 18th. Sent to convalescent ward in the country.

October 7th. Returns much stronger. Weight, one hundred and forty-four pounds; no cough.

October 19th. Weight, one hundred and fifty-two pounds.

October 25th. Goes to work as teamster.

November 30th. Weight, one hundred and fifty-nine pounds.

The following are all the recorded cases of gastrotomy for removal of foreign bodies from the stomach to which any allusion is made by writers on this subject, with a few additional ones which I have been able to collect.

CASES OF GASTROTOMY FOR REMOVAL OF FOREIGN BODIES.

1602. The first authentic case on record in which gastrotomy was done for the removal of a foreign body is that of Florian Mathis, in Prague, surgeon to the Emperor Leopold, who successfully extracted a knife twenty-one centimeters long, from the stomach of a Bohemian juggler in 1602. The knife had remained in the stomach fifty-one days, without causing any great inconvenience or suffering. After the application of plasters, the point of the knife-blade penetrated the pyloric end of the stomach, and was there found and removed. After a few weeks, complete recovery.[10]

1635, July 9th. Dr. Daniel Schwabe, of Königsburg, did gastrotomy for the removal of a table-knife eighteen centimeters long and one and a half centimeters broad, swallowed May 25th, 1635, and which had remained in the stomach forty-one days, without causing any essential trouble. A cut was made on the left side beneath the short ribs, the stomach was pierced with curved needles, and the knife drawn out through a cut made upon the knife blade, which could be felt through the walls. The wound in the stomach was left to take care of itself, and the abdominal wound united with five stitches. Complete recovery.[11] "This man, Grunheyde, has played many parts, figuring in Schwabe's case, Gruger's, Becker's, Shoval's, and Mentzer's, and referred to by the careless even as Nevin's or Larrey's."

1692. Wesener, in Halle, removed from a boy of sixteen years, a knife, which had remained in the stomach seven months without causing any severe symptoms. Seven months after swallowing the knife, an ulceration broke out three fingers breadths below the pit of the stomach, with marked redness. Six days afterwards spontaneous opening, with fœtid pus. Nine weeks later the knife projected from the wound; its point was fastened to the abdominal wall with silk threads. Two weeks later it was entirely removed. Complete recovery.[12]

1720. Hübner, in Rastemberg, removed from a woman a knife sixteen and a half centimeters long, which had been in the stomach eleven days. For three days no disturbance; then sharp pain, and shortly after, the knife point could be felt in the left side. On the eleventh day an incision was made in the left hypochondrium, in the spot where there was evidence of slight suppuration. At this point the knife had penetrated the stomach wall. Recovery in a short time.[13]

1786. Frizac, in Toulouse, removed a knife four and a half centimeters long from the stomach of a porter. An incision was made in the epigastrium, parallel to the linea alba, through which the point of the blade of the knife could be felt, and which had already pierced the stomach wall. The point was grasped with forceps, the opening in the stomach enlarged, and the knife extracted. Two stitches were put in the stomach wound, and one quill suture in the abdominal wound. Healing of the wound and recovery. Baron Larrey was present at this operation, and the case is probably authentic, although it has been overlooked until very recently.[14]

1819. Cayroche removed from a woman of twenty-four a silver fork seventeen centimeters long and two centimeters broad, which had been in the stomach two hundred and twenty-nine days. The fork could be felt through the epigastrium, the handle to the right and the prongs to the left. In five months severe vomiting, then pain, emaciation, swelling in the left side as large as a hen's egg. An incision five centimeters long was made over the tumor from above downwards, the rectus abdominus was drawn to one side, and the stomach was opened. The fork was withdrawn tines first. Recovery in fifty-one days.

1822. Reynaud, in Grénoble, removed a fork from the stomach of a young juggler, where it had remained thirty-one days. Gastrotomy was done on the right side of the abdomen, where the foreign body could be felt. Complete recovery. Man still living in 1875.[15]

1823. A Dr. L——, endorsed by Sedillot, took a silver spoon from the stomach of a soldier.[16] This may be the same case as that quoted by Credé as follows: —

1823. Bertherand removed a silver-coffee spoon from a cavalry man. It had remained in the stomach one week, and had caused pain there, with swelling of the epigastrium. With the exploring needle a hard resonant body was felt. The cut was enlarged, and the spoon withdrawn with forceps. The stomach and abdominal surfaces everywhere adherent. Simple dressing. Rapid and permanent recovery.[17]

1830. Garcia is said to have removed a stick ten inches long from the stomach.[18] This case is considered doubtful.

1836. Fideli, in Riva. A peasant woman, fifty years of age, swallowed a brass fork with four tines, ten inches long without the handle, which remained in the stomach two and a half years. She had terrible pain, sleeplessness, severe cramps, vomiting with every attempt to take food. Fifteen months later an abscess appeared in the right hypochondrium. Two months later a large amount of pus was discharged through the mouth. One month later opening of the abscess outwardly. After repeated closing and breaking out of the wound, the sharp end of the fork appeared. For eleven months the condition continued the same, without the fork protruding any farther. Then for the first time the opening of the abscess was enlarged, and the fork removed. Convulsions followed, with trifling hæmorrhage. For thirty hours' food was discharged through the wound. Fifteen days later it was healed.

1848. Tilanus, in Leiden, removed a silver fork from the stomach of an insane girl thirty-two years old. The fork was twenty-one centimeters long. There was also in the stomach a piece of earthen ware two centimeters long, one centimeter thick, of pyramidal form. Soon after swallowing them she became emaciated and weak, with intense dysphagia. Location of the foreign body made out by palpation. Patient etherized. An incision eight centimeters long, along the linea alba, from a point three centimeters below the ensiform cartilage, was made. The stomach could not be seen, but it could be felt along the left border of the wound. It was drawn forward and fixed with two forceps. An incision two centimeters long was made through the anterior wall of the stomach, and was accompanied by quite severe hæmorrhage. After prolonged efforts, the fork, as well as the piece of earthen ware, was discovered and removed. The wound in the stomach was closed with five sutures, the ends of which were left sticking out of the lower angle of the wound. The abdominal wound was closed with simple sutures, and adhesive plaster placed over all. On the first and second days occasional vomiting of a greenish yellow fluid. Abdomen somewhat painful, tender, and tympanitic. Pulse 100° on the second day, small and weak. Death on the morning of the third day. Autopsy. — Plastic exudation in the neighborhood of the wound. The stomach, liver and abdominal wall glued together. The stomach wound entirely closed. Great dilation of the stomach. The upper third of the œsophagus considerably wounded and perforated in the neighborhood of the larynx. Suppurating sinus near the thyroid gland.[19]

1855. J. Bell's case, also reported by T. B. Neal.[20] This was a man who, in a drunken fit, in imitation of a juggler, swallowed, on a bet, a bar of lead ten inches long by three-fourths by one-half, weighing one pound, on Christmas day, 1854. Pain, vomiting and gastritis supervened. January 3d, 1855, an incision four inches long was made from the umbilicus to the false ribs, two inches to the left of the median line. An incision was

[20] This case has been quoted both by Poulet and by Credé, as two distinct cases.

made into the stomach just long enough to get the bar out. No sutures were put into the stomach itself, the contraction of its walls being sufficient to bring the edges of the wound together. The abdominal wound was closed with sutures. Thirteen days later the wound was entirely healed. February 19th he was about his work.[21]

1856. Glück, in 1856, made an unsuccessful attempt to remove a laryngeal probang which had been accidentally introduced into the stomach.[22]

1856. ——— in Frankreich von? A fork was removed by gastrotomy, with recovery.[23]

1857. Bouchet, in Lyons, removed a silver fork from a woman's stomach. Result unknown.[25]

1858. Hohlbeck, in Wodkinsk. An iron table fork, with wooden handle, twenty-one centimeters long, was swallowed by a peasant with delirium tremens, and remained in his stomach six and a half months. There was pain in the stomach, loss of appetite, nausea and vomiting. There was found in the left side of the peritoneal cavity, between the seventh and eighth ribs, a small fluctuating spot with a fistula, secreting fetid pus, in which the metallic body could be felt. An incision was made at this point, and the fork extracted. The patient died three months later with caries of the sternum and ribs. Autopsy showed complete adhesion of the stomach wound with the abdominal parietes.[28]

1875–6. Leon Labbé. L., eighteen years, March 30, 1874, swallowed a German-silver fork with five prongs, while imitating a juggler. Had immediate symptoms of asphyxia which suddenly ceased after passing larynx. Fifteen days after there was intense pain and repeated syncope. When this attack had passed, a swelling appeared, corresponding to the point occupied by the greater curvature of the stomach. From this time the patient had alternations of pain and complete freedom from it. His general health became much affected. After some months it was decided to attempt an operation, as the teeth of the fork could be distinctly felt at the limit of the hypochondrium and epigastrium. Caustics were first applied to make the stomach adhere to the abdominal wall, without success. April 9th, an incision was made, and by the aid of forceps, a part of the stomach was drawn through the opening. The fold thus formed was held by a thread. With eight sutures the stomach was fastened to the circumference of the wound. The wall of the stomach was then opened, and with a little manipulation, the fork was removed. Rapid and complete recovery.[24]

1879. J. C. McKee, America.[25] January 15, 1879, a laborer, aged twenty-eight, was playing slight-of-hand tricks with a piece of copper wire, three inches long, which he made mysteriously disappear into his nostril. Suddenly it disappeared into the pharynx and the stomach. Took castor oil without benefit. Worked for two months; then acute pain came on near umbilicus on right side of abdomen, three inches to right below. Tumor gradually formed. Cut down upon the tumor May 4th, and the wire was removed. In this case the foreign body was probably not in the stomach.

1880. Billé's case.[26] This patient used a pencil covered by a sponge, and the whole attached to a new silver wire fifty centimeters long, for the purpose of clearing the slime out of his œsophagus. May 2, 1877, it broke off, and part was left in the œsophagus. Billé first did an œsophagotomy at the level of the hyoid bone, but was not able to grasp the wire. Later he did gastrotomy by an incision through the abdominal wall and peritoneum three and a half centimeters long, two fingers' breadth below the margin of the ribs. An incision two and a half centimeters long was made into the stomach, which was made solid with the abdominal wall before incising the mucous coat. The sponge was felt near the pylorus. This was seized with a pair of forceps and the whole extracted. The upper end of the wire was in the lower extremity of the œsophagus. The whole fragment was thirty-one and five-tenths centimeters long. Patient died five days after operation.

1880. Fleury, L. A.,[27] South America, reports the case of a cook who, July 8, 1880, while trying to amuse some children by pretending to swallow a plated dinner fork, accidentally let it slip from his fingers, and felt it passing down into his stomach. There was no inconvenience except slight nausea and vomiting. September 8th, two months later, while jumping a low wall, felt a sharp, stinging pain in the abdomen. The prongs of the fork could be felt distinctly through the abdominal wall. Operation September 14, 1880. A cut three inches long was made in the epigastric region, along the external border of the left *rectus abdominis* at the point where the body was felt. A circular incision was made around the tines of the fork in the stomach wall, and the fork extracted. The handle was in the pylorus and the prongs in the anterior surface of the stomach. Next day patient doing well. Ice water diet. Complete recovery.

1880. Felizet[28] removed a spoon from a patient of nineteen. The stomach was first inflated with ether, so as to be easily seen and grasped. Discharged well in three weeks.

1882. Dr. Beattie Bean sent an account of a gastrotomy for foreign body to the *Lancet* from Hong Kong. Ito, a young man, swallowed a tooth-brush. Five days afterwards Dr. Hashimoto, principal of the highest medical college in Japan, was called in. He advised opening the stomach. A cross cut was made, and the stomach laid bare. The brush was found embedded with its sharp handle partly through the walls. It was taken out, and both wounds deftly sewn up. The man was reported to be in a fair way to recovery.[29]

1883. Kocher, Berne, removed a broken coin-probang from the stomach of a man thirty-seven years old. It had been there one day, and caused hardly any disturbance. An incision was made through the abdominal wall two centimeters below the margin of the ribs. The stomach was opened by an incision three centimeters long, midway between the greater and lesser curvatures, through which the foreign body was extracted. The wound in the stomach was closed with ten Lembert sutures. Recovery without interruption.[30]

1883. Gussenbauer, Prague. A sword-swallower, nineteen years of age, broke off into his stomach a sword blade twenty-seven centimeters long, two centimeters broad; the broken end was jagged and the point rounded. It remained in his stomach two days. Emetics and suspending by the feet were tried unsuccessfully. On the following day, by sounding and palpation, the foreign body could not be detected. There was fever, vomiting and hiccough. After cutting through the abdominal wall, the point of the sword could be felt wholly in the cavity of the stomach, lying obliquely from above down to the left. After cutting through the stomach wall, the body was removed with little trouble. Death followed in two days from septic peritonitis. The point of the sword had pierced the stomach wall, and the other end had perforated the œsophagus.[30]

1882. Schönborn, Königsberg, reported at the Congress of German surgeons in Berlin, a case of gastrotomy for the removal of a ball of hair from the stomach of a young girl. She had been in the habit of biting off the ends of her hair, and swallowing them to clear her voice. A tumor was found in the left side of the abdomen, supposed to be at the time either spleen, omentum, or floating kidney. It was found to be a bundle of matted hair lying in the stomach as large as two fists. Laparotomy was performed and the tumor easily found. A long incision was made through the anterior wall of the stomach, and the ball of hair found lying free in its cavity. It was removed, and the stomach wound closed with sixty-five Madelung stitches. Both

wounds healed by first intention, and patient was discharged in three weeks.[31]

1883. Knowlsley Thornton reported a similar case in 1883. That of a young girl of seventeen, who had for some years swallowed the combings of her hair. There was a tumor in the region of her stomach. A transverse incision was made into the stomach to avoid the vessels. The abdominal cut was in the linea alba. A mass of hair nine inches long was removed from the stomach, and the wound closed with fifteen sutures. Next day one sponge was missed. The abdominal wound was re-opened, and the missing sponge found. The patient made a good recovery.[32]

1883. Gerard, in Bourgueil. A man of thirty years had lodged in his stomach for six weeks a piece of elm-wood twenty-one and five-tenths centimeters long. There was pain, nausea and vomiting. Purgatives were used without success. Six weeks later an abscess appeared four centimeters under the border of the ribs, which was opened, and in the bottom of it the foreign body could be felt. Ten centimeters of it was cut off and removed. He gave forty grammes of castor oil, and the rest of the piece came with the stool on the following morning. Recovery in fourteen days.[33]

1885. Billroth. A girl of nineteen years of age swallowed a plate of six teeth. Palpation of the abdomen was painless, and nothing abnormal could be detected. An incision eleven centimeters long, beginning seven centimeters under the ensiform cartilage in the median line, and extending obliquely downward and to the left. After a long search, the foreign body was felt and fixed. It was shoved into a part of the stomach which was drawn forward by two stitches (thread slings). Opening of stomach, extraction, closure with superficial stitches and several Lembert stitches. Stitch of abdominal wall in three stages.[31]

1885. Credé, Dresden. A hair-dresser, twenty-four years of age, swallowed, in his sleep, a plate with eight teeth and two clamps. In the first week there was pain in the pylorus, then nausea, vomiting, sleeplessness, and great excitement. An oblique cut was made, beginning at the ensiform cartilage, parallel to the ribs, twelve centimeters long. Out of this the stomach was drawn. The plate could be felt through the pylorus. A cut was made through the stomach wall, beginning two inches from the pylorus, and extending five centimeters, through which the teeth were removed. The stomach was sewed up with three rows of stitches, and replaced in the abdominal cavity. The abdominal wound was sutured and dressed with iodoform. Very little reaction, no vomiting. Discharged on the twenty-first day in good health.[31]

1886. "Dr. Bernays, of St. Louis, last week successfully performed a gastrotomy upon a tailor, aged forty, for the extraction of an ordinary silver-plated dinner knife nine and a half inches long, which he had swallowed in imitation of the juggler's feat."[34]

Polaillon, of Paris, is said to have removed a foreign body from the stomach this year with recovery.

Following the classification of cases adopted by Credé we have the following tables of gastrotomies:

(*a*) For foreign body in œsophagus.

No.	Operator.	Nature of Body.	Length of Cut.	Result.
1	Richardson, 1886.	Set of teeth.	6 inches.	Recovery.

(*b*) For foreign body in stomach.

I

CASES WHERE THE STOMACH WALLS ARE UNINJURED AND NON-ADHERENT.

No.	Operator.	Nature of Body.	Length of Cut.	Result.

From the above tables we see: (1) 12 authentic cases where the stomach, uninjured and non-adherent, has been opened. Of these 3 died. (2) 11 cases where the stomach was injured and adherent, with 10 recoveries and 1 death. (3) 10 the authenticity of which is doubtful, with 6 recoveries, 1 death, and 3 doubtful, or, as yet unreported. Total of 33 cases, with 26 recoveries, 4 deaths, and 3 uncertain. Credé collected 26 cases. Of these the same one is mentioned twice — as J. Bell's and W. Bell's. Of these 25 cases, 21 recovered and 4 died. This list includes all the cases he was able to find, both the authentic and the doubtful. One case recorded by him, that of "J. Meckel" (J. A. McKee, U. S. A.), was probably not a gastrotomy, as the foreign body presented itself at the abdominal wall to the right and below the umbilicus.[35] This leaves his cases as 20 recoveries and 4 deaths.

We may therefore assert that the operation is a very successful one. The numerous recorded deaths which have followed the impaction of foreign bodies in the œsophagus, whether attended by the most violent and painful manifestations of their presence, or even unaccompanied by any symptoms whatever, the constant danger of inflammation, ulceration, perforation of important structures, hæmorrhage and exhaustion, make it imperative that the surgeon should exhaust all the resources of his art to afford relief.

When all other means have failed, and the foreign body is found by measurement to be within reach by œsophagotomy, this should be done as soon as serious symptoms appear. If it is found that the body is within reach from below, that is, more than thirteen, possibly twelve inches from the incision, and if the patient is in danger, as shown by constitutional symptoms, or imperilled by starvation, the stomach should be opened immediately, and attempts made to dislodge. If the symptoms are not urgent, a reasonable time should be allowed for natural efforts to aid in expulsion, but the operation should be done early enough to prevent the secondary changes of ulceration and perforation. If it is demonstrated that the foreign body is beyond the reach of œsophagotomy, and yet too high to be easily reached by the fingers from below, suitable instruments should be introduced through the stomach, guided by the finger, if necessary, for cutting, crushing, grasping or pulling down. I am convinced that in most persons no part of the œsophagus is beyond the reach of the fingers. In some cases there may be a very narrow interval which cannot be reached from one end or the other of the tube, but the surgeon's finger can be brought so near even in these cases that it may fairly be stated there is no part of the œsophageal canal in which a foreign body may become lodged, which cannot be reached with the finger, or, at least, to which an instrument cannot be guided safely and intelligently.

Hospital Practice and Clinical Memoranda.

A CASE OF MALIGNANT ENDOCARDITIS.[1]

BY F. C. SHATTUCK, M.D.,
Visiting Physician, Massachusetts General Hospital.

A MAN, twenty-six years of age, entered my service at the Massachusetts General Hospital, July 26, 1886. On entrance, he was so deaf that a complete history could not be obtained. It was ascertained that he had long been deaf, but had grown much worse in that respect since his present illness came on. Three months before entrance he began to lose flesh and strength, and to have "hot or cold spells," compelling him to give up work. He later improved somewhat, but was obliged to give up again two weeks ago, on account of increased weakness. For the past ten days he has had marked chills, two or more daily. For the past few days he has vomited every morning. Complains somewhat of soreness of throat. On entrance he had a marked chill, lasting an hour, and recurring twice, accompanied by pain in the præcordial region, which was relieved by a sinapism. He complained also of pain in both hips and thighs, and of great restlessness especially at night. Appetite poor; bowels constipated.

The patient was fairly developed, emaciated, pale; the tongue was clean. The fauces were slightly reddened. He was unable to walk, but could stand, and move his legs freely in bed. There was marked hyperæsthesia from the chest down; the cutaneous and deep reflexes were exaggerated; ankle clonus was present. The internal viscera gave negative results to examination. The mind was clear.

July 28th. Chills have recurred twice daily. Complains of pain in hips. The apex of the heart is in the fifth interspace, just outside the mammillary line. There seems to be tenderness in and above the region of the apex. The first sound at the apex is dull, and accompanied by a faint, systolic souffle, which can be followed toward the pulmonic area. The pulmonic second is accentuated.

July 29th. During examination, twitching came on in the right, and later in the left arm, with lateral and upward movements of the eye-balls, and closure of the lids. The arms were then held in the air, and soon the convulsive movements extended to the legs, and became general. The patient cried out, and seemed to be conscious. The convulsive movements lasted perhaps ten minutes, and were renewed on striking the muscles and the patellar tendons.

July 31st. The chills continued. The heart's action was regular, and the souffle was more distinct, loudest at the apex. During the visit there was a recurrence of the convulsive movements noted the 29th, and again after examination. The face did not change color. The general condition remained about the same, except that he was losing strength. There was a slight yellowish tinge in the skin, but no discoloration of the conjunctivæ; no skin eruption. During the chills the heart's action was very violent, and the patient complained of palpitation.

August 2d. The patient was cheerful, mentally clear, and in no pain. The heart's action was very feeble, but regular; the souffle was scarcely audible.

August 3d. The temperature sank to 95° last night, and remains subnormal. The pulse is regular, but weak. At 2.30, P. M., he told the nurse a chill was coming on, turned over in bed, and died.

Autopsy by Dr. Fitz.

Spinal cord not examined. Brain showed nothing abnormal. *Heart* — Pericardium contained some ℥vi clear, yellow fluid. At apex of right ventricle, in front, was a group of several thick, fibrous villi, each about a quarter of an inch long. Pericardium over left auricle thickened in spots. Heart increased in size perhaps one-fourth. Both sides, especially the right, distended with clotted blood, differentiated into red and white portions. Aortic and pulmonic valves sufficient by hydrostatic test. The two anterior aortic crescents fused, the septum between thickened and retracted. The curtains thickened. From their ventricular surface projected a fleshy nodule of reddish-yellow color, as large as a filbert. It was intimately connected with the valve-curtains, whose consistency was diminished. Both were perforated. The myocardium contained a round, continuous nodule, also as large as a filbert, composed of reddish-gray, puriform material. The other valves showed nothing abnormal. Both ventricles were moderately dilated, the muscular walls of the left ventricle thinned, the muscle gray and opaque. No infectious or other emboli were found, and the other organs presented no noteworthy changes.

To sum up: A young man, for the past three months, has suffered from chills and increasing weakness. After careful examination, the conclusion is reached that the chills are pyæmic, and physical exploration affords but little information as to the source of the pyæmia. There is, however, slight cardiac enlargement, and a souffle at the apex develops and increases under observation. Convulsions appear and recur, more marked in the trunk and extremities than in the face, and the patient dies of exhaustion.

The probable diagnosis of malignant endocarditis was made the third or fourth day after entrance to the hospital, and confirmed by the autopsy. This diagnosis was reached by exclusion, the symptoms being thus explained better than in any other way.

The autopsy showed one thing which was indicated neither by symptoms nor signs during life — namely, an old endocarditis, affecting the aortic valves. The changes in the valves were marked enough to the eye, but, inasmuch as they gave rise to no obstruction at, or regurgitation through the orifice, they had no immediate consequences. If a history of rheumatism, with cardiac complication, had been obtained, as, perhaps, might have been the case had the extreme deafness not prevented communication with the patient in great measure, the diagnosis would have been still

[1] Read at the Section of Clinical Medicine, Pathology, and Hygiene of the Suffolk District Medical Society, November 10, 1886.

more clear; for it is well known that malignant endocarditis is more apt to attack a diseased than a healthy valve, though the latter is not exempt.[2] It is interesting to note that the systolic souffle heard during life had its maximum intensity in the region of the apex, and was, consequently, probably dynamic, and quite independent of the changes in the aortic valves. The spinal cord was, unfortunately, not examined, so that we remain in ignorance as to whether the convulsions were functional, or dependent on more or less gross lesions in that centre.

As regards symptoms, malignant endocarditis may well be characterized as multiform. It may be primary, but, in the majority of cases, is secondary. It may be the origin of a general sepsis; simply a portion of a general sepsis starting from a wound or injury, the puerperal process, etc.; or it may develop during the course of a general disease, such as acute rheumatism or pneumonia. The first two types, which were clearly differentiated, were the typhoid and the pyæmic; but, as the number of reported cases has increased, the cardiac, the cerebro-spinal and cerebral, and the malarial types have been added, and are dwelt upon by Osler in his Gulstonian Lectures for 1885. In several instances the affection has been diagnosticated as acute yellow atrophy of the liver during life. In other words, the endocarditic changes may be foreshadowed by no direct symptoms, the affection running its course under the guise of one or another of the severe infectious diseases. If this fact is borne in mind, careful and comprehensive study will lead to the accurate diagnosis of some obscure and anomalous cases. With the greatest care, skill, and knowledge, however, the diagnosis can, in some cases, be first made after the patient has reached the post-mortem table. But the number of these cases will diminish as the knowledge of the affection becomes more general. The above case is a good illustration of the primary pyæmic type, and will, I hope, be of special interest to the Section in connection with the case reported and the discussion evoked last spring by Dr. Grace Wolcott.

CASES OF PERFORATION OF THE APPENDIX CŒCI AND OF INTESTINAL OBSTRUCTION.[1]

BY E. W. CUSHING, M. D.

The first case was a boy eight years old, previously in good health, to whom I was called in September, on a Saturday, finding him with symptoms of acute peritonitis with evidence of fluid in the abdominal cavity.

The history showed that fourteen days previously, while in good health, the boy had been roughly used by some of his playmates who laid him in a trench, and played they were burying him, by putting a paving stone on his belly, one of the largest of them seating himself on the stone in this position.

The patient seemed hurt internally, and was in bed one day, but went to school on the third day, staying there a week, when after some scuffle he had to keep his bed for two or three days longer. However, he went to school again on Monday and Tuesday, on which day he stated that the teacher "licked him like all sixty;" on returning home one of his friends, fourteen years old, kicked him in the belly, so that he doubled up and came in screaming with pain. He went to bed, but his mother did not recognize the severity of the case until Friday, and first secured medical advice on Saturday.

Suspecting rupture or injury of the intestine, I explained the imminent danger and advised laparotomy as a not very hopeful expedient. The mother consenting, Dr. H. O. Marcy was sought in counsel, and he kindly came with a nurse from our hospital and all the needed instruments.

After the usual preparations, Dr. Marcy approving the operation and kindly assisting, I made an incision in the median line and removed about a pint of fœtid pus from among the intestines which were quite adherent and could only be separated with difficulty. It seemed impossible to really search for any rupture owing to the adhesions, and the cœcum and vermiform appendix were quite inaccessible. With the irrigator the thick pus was flushed out of the various pockets, two drainage-tubes inserted and the abdomen sewed up.

The little patient came out of the ether well, was quite comfortable and conscious, but failed and died the next day. It seemed most probable that the first injury had given rise to some circumscribed peritonitis and that the last kick had made this general, perhaps by rupturing the limiting adhesions. Perforation of the appendix was not considered at all probable, owing to the youth of the patient and the clear history of injury.

As the case seemed a clear one of assault, I notified the medical examiner, Dr. Draper, who laid the facts before the district attorney.

The latter declined to interfere on the ground that the fact that the boy continued to play with the others who had used him so roughly, showed that he considered it all as within the limits of "fun," and not as an assault. No malice was charged. Dr. Draper therefore declined to make an autopsy officially.

Dr. Marcy and I made it, however, and found no rupture of the intestine, but a perforation of the vermiform appendix. The latter lay in a sort of abscess cavity, surrounded by strong adhesions, but communicating with the rest of the abdominal cavity. The appendix being removed, was found to have a wide opening or calibre, and in it was a concretion as large as a pea. Over this was an ulceration of the mucous membrane communicating with the abdominal cavity by a fine opening, just large enough to admit a probe.

Whether the injury fourteen days before death had any share in causing the inflammation of the appendix with subsequent perforation, and whether this was at first circumscribed and became general after the kick, it is difficult to decide, but on the whole, and in view of the strength of the adhesions this seems not improbable. The case is instructive, as is also number three, in showing how necessary it is in all such operations to examine the appendix, and how a history of violence, which may be only a coincidence, should not lead to hasty conclusion.

Case II. A single woman, with out apparentcause or error of diet, was taken with a "bilious attack" with vomiting, some colic, etc., at night. I was called in the morning and found symptoms of an ordinary attack of indigestion such as is very common in summer.

There was, however, an abdominal tumor, reaching from two inches to the left of the median line and an

[1] Read at the Section for Clinical Medicine, Pathology and Hygiene of the Suffolk District Medical Society, Nov. 10, 1886.

[2] Fusion of two of the aortic cusps, a frequent result of sclerotic changes, was marked in this case.

inch below the umbilicus, across to the right iliac fossa. It was hard, rounded, and immovable. Ordered Hunyadi water, ice pills, and enema. At one o'clock she was comfortable, but soon after vomiting recommenced with much pain. The latter was relieved somewhat by the inunction of oleate of morphine, but the vomiting persisted and nothing came from the bowels after repeated enemata.

By about five o'clock the condition of the patient was becoming grave, for the fluid vomited had a marked intestinal odor, not fæcal, but like what is noticed on opening the abdomen soon after death.

I laid before the family the danger of the situation, explained that the evident obstruction might call for operative measures, and asked for a consultation with Dr. Cheever, who was in the vicinity, and who kindly came, arriving about seven o'clock.

By this time, the condition of the patient was desperate; she was in fact, in full collapse, nearly pulseless, cold, with hollow eyes, pinched nose, the typical Hippocratic countenance.

She had several times vomited large quantities of slightly yellowish, nearly clear, intestinal fluid which welled up without apparent effort; at one time nearly a quart was thus ejected.

On examination, Dr. Cheever thought the patient too weak for laparotomy, and it seemed to us both that the tumor, blocking the whole right iliac region, and being firm and immovable, was probably malignant, and therefore there would be nothing gained by an operation in such a desperate condition. Dr. Cheever therefore left, encouraging me to persist in my efforts to the end, for sometimes such cases rallied.

First, I gave five or six hypodermics of brandy, which, however, did not seem to do much good; by this time she was wholly pulseless and scarcely conscious. Meanwhile, having had some stock soup heated, an enema of this with brandy, about four ounces of the mixture, was given hourly. By the mouth I gave brandy and gum arabic water, in small teaspoonfuls. This remained on the stomach; the enemata also were retained.

About eleven o'clock I heard a sound as of flatus passing through the intestines, which greatly encouraged me, and I gave an enema of about a pint of the soup.

Presently this was followed by a discharge of fæcal matter, then another, the vomiting meanwhile had ceased, and gradually hour by hour the pulse and color returned and the patient rallied.

The next day a number of very large evacuations of old fæcal accumulations took place, and to my surprise the connection between the round abdominal tumor and the right iliac fossa had disappeared.

The tumor remained round, hard, freely movable, about as large as a cocoanut.

A sister of this patient died some years previously with what was said to have been a malignant growth, but the report of the autopsy shows it to have been a fibroid of the uterus blocking up the pelvis and causing directly intestinal obstruction.

In my patient, the obstruction was indirect through accumulated fæces.

It is interesting to note that although water and soup with and without castor oil in enema appeared to have no effect in softening the impacted fæces, yet the warm greasy soup seemed to soak into and soften the mass, at the same time nourishing the patient at a most critical period. However, I think that it would not be safe to expect such a fortunate outcome in a similar case where the nature and previous condition of the tumor (which appears to be ovarian) were known beforehand, but that a prompt laparotomy would be far less dangerous than such a terrific attack.

The continuous vomiting by a sort of reversed intestinal peristalsis is interesting in connection with the next case.

CASE III. I was present to assist Dr. Marcy in a case where there were symptoms of acute intestinal obstruction with vomiting and slight fever in a strong, healthy, muscular man. Dr. Lane, of Cambridge, had exhausted all medical measures and summoned Dr. Marcy on the fifth day of the illness. The latter recommended a laparotomy as the only chance. This was done on the next day, and on opening the abdomen and turning the inflated intestines into sublimated towels it was found that there was a twist of the small intestine by which some three feet of bowel was caught in the crescentic fold of the mesentery. This was remedied, and further search revealed some adhesions and flakes of lymph near the cœcum in which the appendix appeared to be bound down.

The man had had symptoms of perityphlitis some eight months and again some two years previously.

There was in the present case no pus to be found, no sign whatever of a general peritonitis, but as on the rectification of the twist the patient passed flatus several times to the evident relief of the distension of the bowel, it seemed injudicious to attempt to stir up the adhesions around the cœcum, at least through the median opening.

The wound was therefore closed with deep sutures, the ether discontinued, and Dr. Marcy was just finishing up a continuous catgut superficial suture when the patient began to vomit, or rather to regurgitate intestinal contents; he had taken nothing into the stomach for many hours, and very little for several days. Dr. Lane, who was in charge of the ether, did what was indicated, but in a moment the man began to choke.

The regurgitation still continued without any intermission. Dr. Marcy rapidly rolled the patient on his side and face, wiped out his mouth, pulled his tongue forward, but still the fluid came from mouth and nose, over a quart in all. The moment it stopped at all we commenced artificial respiration, which was continued for over two hours by the aid of strong and willing friends: Dr. Marcy made sure that nothing was obstructing the larynx, and even turned the patient nearly upside down to let any fluid run out of the lungs. We never ceased our efforts for a moment. The heart was beating perceptibly all the time, and the air certainly passed freely in and out of the lungs, but there was no response of the respiratory centres, and we had to finally give him up as dead, apparently strangled by inspiring the regurgitated fluids.

At the autopsy no examination of lungs or head was permitted, but we found in the intestines the evidences of acute congestion of the parts which had been constricted, and found the appendix doubled and twisted on itself and adherent at one part, which on separation, opened the lumen of the appendix in two places.

There appeared to be an acute inflammation of the appendix with double perforation of the adherent part, but the whole was shut off from the peritoneal cavity.

Nevertheless, by this irritation it seems that the peristalsis of the bowels was so disturbed that the small intestines became twisted, and when untwisted appear to have discharged their fluid, not fæcal contents, upwards instead of downwards with the fatal result above described.

An accident of this kind in an operation is very rare, and is here reported because of the valuable lesson taught thereby. This case, as well as the first, emphasizes the importance of finding and examining the appendix in all cases of laparotomy for obscure abdominal symptoms.

Reports of Societies.

MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

NOVEMBER 10th, 1886.

Meeting opened at 8 o'clock, DR. F. I. KNIGHT, in the Chair.

The first business of the evening was the election of a chairman for the ensuing year. The chairman is usually chosen at the first meeting of the year, but the preceding meeting was devoted to the subject of Filtration of Water, and but few members of the Section were present, therefore the election was deferred to this meeting. The secretary stated that the office of chairman had been usually filled by the same incumbent for the period of two years, and that Dr. Knight has served one year and has not expressed himself as averse to a further period of service. Dr. R. H. Fitz thereupon nominated Dr. F. I. Knight as chairman for the coming year. The motion was seconded by several members, and being put by the secretary, was unanimously carried. Dr. Knight responded in a few well-chosen words, thanking the members for the compliment thus done him, and accepted the position.

The first paper of the evening was by DR. P. C. KNAPP, and was entitled

A CASE OF PROFESSIONAL NEUROSIS OF CO-ORDINATION, OF UNUSUAL ORIGIN,

of which the following is an abstract.

The professional neuroses, of which writer's cramp is the commonest form, may arise from any occupation requiring a muscle or a group of muscles to be kept in a more or less firm contraction, together with fine movements of co-ordination. The pathology is still obscure, but some cases closely resemble sub-acute neuritis. The symptoms were arranged by Benedict into three groups: the spastic, the tremulous, and the paralytic forms. Lewis adds to these two other classes of cases, those attended with pain or perturbed sensation, and those attended with vaso-motor or trophic disturbances. The case in question was considered to be probably a sub-acute neuritis, conforming to Lewis's class of cases attended with pain. The patient was a girl of twenty-three, a carpet-pattern setter, who, after pretty constant work, had had for three or four weeks severe pains in the fore-arms, worst in the left arm. The arms felt lifeless, and the trouble was aggravated by attempts at work or even on performing the finer domestic duties, such as sewing. There was no cramp or disturbance of co-ordination. There was a slight diminution of sensation on the ulnar side of the hands, and some tenderness over the nerve-trunks, especially over the left ulnar nerve near the elbow. As the case was considered a professional neurosis, the carpet works were visited, and the process of pattern-setting examined. Each girl sits in front of a table along which run the threads of the warp of the carpet, which are dyed of various colors to make the pattern. With one hand they have to arrange these threads in the proper order, so that they may come into position to make the pattern true; with the other they pick up the individual threads whose tension is wrong, and tighten or loosen as the case requires. Both manipulations require a certain amount of muscular tension and fine co-ordination, but no other case of the trouble had been heard of at the works, and no similar case had been previously reported, to the writer's knowledge.

DR. C. F. FOLSOM was called upon by the chairman, and responded by saying that the exhaustive study of the professional neuroses made by Dr. Knapp left really very little to be said. Dr. Folsom has seen similar cases from other causes, generally associated with some of the severer forms of nervous disease, frequently among those patients suffering from alcoholism, and has observed that the cramp is not infrequently relieved by treatment or by rest, so that the signs of this affection quite disappear.

DR. W. N. BULLARD stated that he had seen an interesting case on the same day, which bears upon the present subject. The patient is suffering from a neuritis of the median nerve with paralysis in the parts supplied by the branches of this nerve, and tenderness along a part of its course down the arm. In this case there was no cramp.

DR. FOLSOM asked what is the pathology of this affection? Is it cramp, or is it paresis?

DR. KNAPP said that it is difficult to determine in most cases what the original lesion may have been. In this case it seems to have been due to an irritation of the nerve. The pathology of all forms of professional neurosis is so obscure that it is often impossible to determine the character of the lesion. The four varieties of this form of neurosis, the paralytic, the spastic, the tremulous and the painful are often associated and united in the same case, so that an accurate analysis is extremely difficult.

DR. F. C. SHATTUCK then read a paper upon

A CASE OF MALIGNANT ENDOCARDITIS.[1]

DR. R. H. FITZ opened the discussion. He stated that these cases are always of interest with reference to their possible method of origin. In certain instances they appear to represent a septic process which arises in the heart without known external cause, and may excite other more remote septic lesions. In other cases the disease has been considered as of secondary character, and as depending upon some primary lesion of infective nature. The valvular lesion has been claimed to be always due to the invasion of the endocardium, either from the surface or from the blood-vessels within the valves, by micro-organisms. Further observation has shown that though such organisms are frequently and perhaps usually present, in acute cases, yet they are not always to be found. In addition, chronic ulcers of the valves are to be recog-

[1] See page 574 of the Journal.

nized with which no evidences of infection are associated, and in which no organisms have been seen.

Although malignant and ulcerative are often used as equivalent, the former is preferable as a diagnostic term, since both ulcers and vegetations may be present in acute and chronic cases of infectious and non-infectious origin. The relation which the immediate cause of the endocarditis bears to the cause of the infective disease in which it occurs as a secondary affection is to be the object of investigation in the early future. Virchow long ago called attention to the rheumatoid group of lesions in infectious diseases, which might be designated as pyæmia, septicæmia, puerperal fever, etc., and considered the puerperal endocarditis as of parasitic origin. Recent experiments not only confirm this view, but make it probable that a variety of organisms may be concerned in producing the endocarditis, and suggest that the local changes and the remote disturbances may vary in accordance with the special organisms found.

DR. BLODGETT spoke of the difficulty in establishing the diagnosis of malignant endocarditis in accordance with any particular rule or system, and considered that each case presents an entirely new study of symptoms, and must be considered quite independently of previous cases. In a patient which he was so fortunate as to have seen in consultation with Dr. Grace Wolcott some months ago, and of which a report was made to this society, the diagnosis of malignant endocarditis was established before death, as the only condition which could reasonably account for the symptoms in the case. The diagnosis was arrived at by exclusion, as Dr. Shattuck states, was the case in his patient. Here, however, there was a clearer history of previous disease of the heart than was ascertainable in Dr. Shattuck's case, and the patient, except in the last hours, could be communicated with, an intelligent account of the subjective conditions could be obtained.

In this case there were the symptoms of septic metastasis to other parts and organs of the body, notably the larger glandular structures, but unfortunately, no sufficient examination of these suspected locations could be made, and the heart itself was the only portion of the affected tissues which was obtained.

DR. HENRY I. BOWDITCH asked if Dr. Shattuck made an examination of the tissues of the endocardium in relation to micro-organism?

DR. SHATTUCK said that no such examination was made, and that in his report of the case he had purposely omitted any allusion to the subject of micro-organisms, as he had nothing to offer in that direction.

DR. FITZ stated that he was responsible for the introduction of the subject of micro-organisms in connection with this discussion. That already found in cases of malignant endocarditis is identical with one found in pus, the golden staphylococcus, and which seems to attend the suppurative process in most cases. It had been cultivated and its identity thus established. Rabbits inoculated with these cultures died in the course of a few days, and the heart presented the appearances characteristic of malignant endocarditis.

DR. SHATTUCK asked Dr. Fitz if he considered that these cases are not a primary form of disease, but dependent upon the existence of previous infective disease of some other portion of the body?

DR. FITZ replied that the majority of cases are not primary, although cases of primary malignant endocarditis apparently occur. In the secondary variety, the cardiac changes appear to be a local expression of the septic condition, and a source of infection should be suspected in all cases.

DR. E. W. CUSHING spoke upon

FATAL PERFORATION OF THE APPENDIX CŒCI.[1]

DR. H. I. BOWDITCH spoke of the great value of free and frank discussion of scientific communications by the society, and commended the courage with which Dr. Cushing had presented his unfavorable cases. It is not difficult to find the reports of successful operations, but there is a great temptation to refrain from publishing the unsuccessful cases. In the case of the boy first reported by Dr. Cushing, the previous maltreatment of the youth by his playfellows would probably be considered by most surgeons as a full and sufficient cause for the subsequent course of the case. It would certainly satisfy all the requirements of the lesions found at the operation and after death, and Dr. Bowditch would think it unnecessary to look further for an exciting cause. If, however, at the time of the operation by laparotomy, the search had been carried further, and the appendix with its contents had been removed, would not the chance of recovery have been materially improved? At the time the abdomen was opened the dangers of the case would not have been seriously increased by the additional exposure of the peritoneum necessary to the prolonged examination for a cause of the symptoms, and it would seem that this should always be done. The abdomen should be thoroughly searched when it is necessary to open it at all, and thus the operation be made to yield the utmost of benefit to the patient. It is advisable to use all the means in our possession, and not to close the abdomen until a thorough search has been made in every part for the cause of the trouble.

DR. CUSHING replied that he could not have done more than he did at the time. The peritoneal adhesions were very tough and resistent, the bowels were matted together in an inextricable manner, and there was nothing to call attention to the appendix. At the same time, Dr. Cushing would do a more extensive operation in another similar case. Had the operation been located over the appendix, the concretion would have been undoubtedly found and removed. At the same time the case is not reported as a glorious triumph of surgery, but as an illustration of the unexpected difficulties which may be encountered in any surgical procedure of so great gravity as the present. Dr. Cushing asked Dr. Fitz if concretions are a frequent occurrence in the appendix at the age of this boy.

DR. FITZ replied that about ten per cent. of cases of inflammed appendix affected patients under ten years of age, and concretions are found in about one-half of all cases. Dr. Fitz added that in the case reported, only a part of the effect of the peritonitis was removed by the operation, and a large amount of the products of inflammation was not disturbed. The course of the case might perhaps have been more favorably modified had the means of surgical relief been more thoroughly carried out. In a similar case known to the speaker, the amount of inflammatory disturbance was so great that another distinct incision of the abdominal parietes was made, and drainage established, and the patient recovered.

DR. CUSHING said that he wished to hear the views of the members upon the unexpected and enormous

[1] See page 575 of this Journal.

regurgitation of liquid from the stomach in the third case reported. This is a new contingency in his experience in abdominal section, and certainly ended the life of one patient in an otherwise favorable condition for relief from operation, by immediate suffocation.

Dr. Fitz asked the reason for the belief that the patient died from suffocation?

Dr. Cushing replied that the patient began to vomit during the operation, but soon all effort at active vomiting ceased and the fluid simply flowed in enormous amount from the mouth, resisting all attempts at its control, and the patient expired.

Dr. Fitz remarked that there seemed no sufficient ground for the statement that the patient died from suffocation, even under the condition described.

Dr. Cushing replied that the man died, anyway, with sudden cessation of respiration, while the heart continued to beat for nearly half an hour.

Dr. Fitz asked if anything were found in the lungs?

Dr. Cushing answered that no autopsy could be obtained.

Dr. Goodwin asked if there were lividity of the face?

Dr. Cushing stated that the man was black. Artificial respiration was commenced and kept up for an hour, but was productive of no improvement in the man's condition.

At this point, Dr. Thomas H. Gage, of Worcester, the President of the Massachusetts Medical Society, was introduced by the chairman in a graceful manner, and in response to a cordial invitation on behalf of the Section he addressed the meeting, returning his thanks for the hearty manner in which he had been received.

The chairman stated that the Secretary desired to present a matter of incidental business to the section. During the past year the secretary has found it necessary to provide certain small sums for the necessary expenses of the section, and the report here presented is an account of those expenditures. The section has no treasury, and there is no provision for meeting these small expenses. There is a committee of finances, to which the matter can be very properly referred, and they will no doubt adopt some method for its liquidation.

By vote the report of the secretary was referred to that committee, with a request that they present a plan for its satisfaction at the next meeting. The section, on motion of Dr. E. W. Cushing, voted to bring before the Suffolk District Medical Society, the question of paying the necessary and proper expenses of the various sections, and the Chairman appointed Dr. Cushing to bring up the matter at the next stated meeting of the Suffolk District Medical Society.

Dr. H. I. Bowditch presented a report of a preliminary character from the committee to whom was referred the subject of the physical culture of children, at the last meeting, in which the committee asked for further time. Dr. Bowditch urged that the Massachusetts Medical Society should take the position that the State should educate the bodies as well as the intellects of the pupils of the public schools. The State should undertake this great work, which is as yet entirely neglected. By vote the report of the committee was laid on the table, and the committee was granted further time.

A communication was read from the Norfolk District Medical Society, announcing that that society had appointed a committee to co-operate with the committee appointed by this society, for the purpose of urging the proper physical training of the children in the public schools.

Adjourned at 9.50 o'clock.

SUFFOLK DISTRICT MEDICAL SOCIETY. SECTION FOR SURGERY.

G. H. Monks, M.D., Secretary.

November 3d, 1886. Dr. George W. Gay in the Chair.

On motion, Dr. J. C. Warren was by acclamation elected Chairman of the Section for the ensuing year.

Dr. M. H. Richardson then read a paper on

A CASE OF GASTROTOMY FOR THE REMOVAL OF A PLATE OF FALSE TEETH LODGED IN THE LOWER END OF THE ŒSOPHAGUS.[1]

Dr. Cheever asked, in reference to the difficulty in introducing the probang into the œsophagus while the patient was lying down, to what the reader considered this due.

Dr. Richardson did not attempt to account for the difficulty, and said that he wished to pass the probang before operating simply to demonstrate the presence of the teeth in the œsophagus, and that, finding difficulty in so doing, he at once abandoned the attempt.

Dr. Cheever said that his reason for asking the question was that he had met with a similar difficulty in five cases in which he had performed œsophagotomy. The probang had in every case slipped into the glotis and had been guided into the œsophagus with difficulty. In connection with the subject of rectal feeding, he would like to know if in this case, the hunger was in any way abated by rectal injections.

Dr. Richardson replied that the patient never complained of hunger, but was often very thirsty.

Dr. Gay stated that in a patient of his, who, for four days after swallowing a foreign body, received no nourishment except from rectal enemata, hunger was present throughout.

Dr. Cheever remarked, as to the lowest point one can reach in the œsophagus from the wound in œsophagotomy, that he had been able to place his finger tip at a point behind the manubrium, and could there feel the pulsations of the aortic arch; and from behind the arch he had extracted a foreign body. He asked what objections there were in Dr. Richardson's case to making the line of incision closer to the margin of the ribs.

Dr. Richardson replied that he knew of no reason why such an incision should not be made, but that his incision seemed to him, on the whole, the safest and most satisfactory.

In reply to another question from Dr. Cheever, as to the difficulty in drawing out the stomach through the abdominal wound, Dr. Richardson said that he found no difficulty whatever in drawing it out freely enough to allow all subsequent manipulations to take place outside the abdominal wound.

Dr. Barnes asked how long one would, in such cases, be justified in waiting before operating.

[1] See page 567 of the Journal.

DR. RICHARDSON stated that he believed in operating as soon as possible after all attempts to dislodge the foreign body by means of the probang had failed. He also emphasized the importance of doing the operation at one sitting.

DR. CHEEVER stated that, in his experience, a foreign body high up in the œsophagus could hardly be tolerated for a longer time than about three days, for by that time exhaustion or abscess would be pretty sure to occur, but that in case the body is lower down the tube, the symptoms do not appear to be so urgent, and operation may therefore be longer postponed.

DR. MIXTER spoke of the value of the stitch used in this case for the purpose of controlling hæmorrhage from the bloodvessels of the stomach.

DR. GREENOUGH asked if caustics applied to the skin could cause adhesions between the stomach and abdominal wall.

DR. RICHARDSON replied that he did not think it possible.

DR. GAY asked how much of the operator's forearm was introduced into the stomach, and whether there was any difficulty in inserting the fingers into the lower end of the œsophagus.

DR. RICHARDSON said that at the moment of extracting the teeth about one half of his forearm was within the abdomen, and that two fingers entered the œsophagus with the greatest ease.

DR. GAY mentioned a case of his own where a child swallowed a silver quarter-dollar, which lodged in the lower part of the œsophagus, where it remained for five months, and was then coughed up. The child is to-day perfectly well, seven years after the accident.

Dr. Gay agreed with Dr. Cheever as to the extreme urgency of the symptoms in cases where a foreign body has lodged high up in the œsophageal tube.

Recent Literature.

Sixth Biennial Report of the State Board of Health of Maryland. Baltimore, 1886.

THIS document contains the report of the efficient Secretary of the Board, Dr. C. W. Chancellor, and also the proceedings and addresses at a Sanitary Council held in 1884.

Sanitary legislation does not appear to have made material progress in Maryland during the two years embraced in the report. "An act to protect the health of those employed in factories and workshops" has become inoperative in consequence of failure to provide for inspection of such places. In consequence of this neglect the State Board offered the following resolution:

"That the aid of the Board be tendered to His Excellency Governor McLane in rendering effective the provisions of the Act" named above. In view of Dr. Chancellor's thorough and fearless service in earlier years in the inspection of the public institutions of Maryland, such an inspection would undoubtedly have proved to be very valuable. The offer of the Board was not accepted. Another important scheme for the drainage of 400,000 acres of the marsh lands of Maryland appears to have met with a similar fate.

Excellent suggestions are stated in the report with reference to the spread of contagious diseases in public schools, in the form of definite rules, containing, in addition to the ordinary regulations, provision for the exclusion of children living in infected houses where common halls or stairways are used by more than one family; also for the exclusion of children, known to have visited or to have attended funerals at infected houses; also permitting a teacher to exclude children ill with certain diseases not usually classed as dangerous. (Such action may properly be taken with reference to contagious skin diseases).

The proceedings of the Sanitary Council consist of a series of papers and discussions upon various subjects pertaining to public health. Dr. Rohe contributes a concise, clearly-stated paper upon "Dangers in Food." Other papers follow, upon Cholera, Diphtheria, Typhoid Fever, Disposal of the Dead, etc.

The report is especially interesting in consequence of the discussion upon Sewage Disposal, by Colonel Waring and Dr. Chancellor, the former advocating "Irrigation as a means of purifying Sewage," his illustrations being mainly taken from the method practised at Berlin and at Paris. He sums up the argument as follows: "I do not advance the facts and opinions set forth as affecting the argument for nor against the Liernur system as a means of sanitary drainage, but only to uphold, as against the assaults of Liernur's adherents, the absolute safety, efficiency and economy of the well and long-tried system of sewage irrigation."

Dr. Chancellor vigorously defends the Liernur system, and appears to have overlooked the principle that rigid plans of sewerage and sewage disposals cannot be laid down for all communities. That which may be practicable in Amsterdam is not necessarily the *summum bonum* for Baltimore.

A Text-Book of Human Physiology, including Histology and Microscopical Anatomy with Special Reference to the Requirements of Practical Medicine. By DR. L. LANDOIS. Second American, translated from the Fifth German Addition. With Additions by William Stirling, M.D., Sc.D., Brackenburg Professor of Physiology and Histology in Owen's (*sic!*) College, etc., etc. 8vo. pp. xi–905 and 583 Illustrations. Philadelphia: P. Blakiston, Son & Co. 1886.

This handsome octavo is the much improved edition of the "Landois-Stirling" in two awkward volumes which appeared at intervals a year or more ago. An entire change of type has resulted in putting the matter of about 1,700 pages of the former edition into about 900 in the one before us. At the same time a very thorough revision has occurred and the number of illustrations has grown from 494 to the number mentioned above. In its new form this is a book which will deserve many friends and interest every reader. Professor Stirling (who has in the interval taken up Gamgee's work at Manchester) shows in his revision a most commendable desire to have his translation keep as nearly abreast of recent research as is practicable, and his success in this direction is marked.

The aim of the book is to present human physiology in its practical aspects as fully as possible, and at the same time to give due consideration to experimental methods and to the pathological variations which are

not too remote. This treatment of physiology has much to recommend it, and this particular volume will be found excellent as a book of reference for practitioners who desire to refresh and rejuvenate their knowledge without giving too great detail or references to the literature. The pages bristle with the names of those whose researches have settled (or unsettled) the questions discussed, but no references are made. As a book for the student it is open to the objection of being too full of statements which are not sufficiently balanced and which may mislead or confuse a beginner unless he carefully follow a very good course of lectures at the same time. In general, too, there is much too little criticism of the results obtained by the different investigators and the sources of error of the apparatus described and figured are not pointed out as they should be. Having made this general objection to the scheme of the book, we have but little to complain of as to the way in which it is carried out. In every chapter which we have examined we have found abundant evidence that the latest researches have been considered and with much completeness; examples may be found in the sections about peptonuria, the part played by the white corpuscles in nutrition, and the function of the kidney. The present state of our knowledge of urea formation as associated with the liver (although it is mentioned and the truth suggested) would seem to deserve fuller treatment, and Seegen's very interesting work on the relation of the liver to sugar is hardly more than hinted at. The chemical portion of the book has been much improved, but permits of still further completeness. There is also a revision of the physiology of deglutition which puts that section on to its proper basis, but due reference to Walton's work would make the note on the epiglottis more satisfactory. We should also like to see Williams's heart apparatus figured among the instruments used in studying that organ, and perhaps the importance of the use of the galvanometer calls for more detailed mention. If we add that the respiratory quotient on page 212 still does not fit the fraction and that the index, full as it is, ought to have a few more cross references, our grumble is at an end.

It is a matter of regret that we have not the space to point out at proper length the merits of this book, which far outweigh its defects. The translator's task has been well performed, and the text runs generally with great smoothness. The additions are judicious and the increase of illustrations is an improvement upon the original. Altogether, Professor Stirling is to be congratulated on the skill with which his work has been done, and we trust that the number of editions to come will correspond to its merits.

— The Bavarian Government has given $50,000 to the widow of the late Dr. von Gudden, who, it will be remembered, was killed by their late insane monarch.

— A young lady of New York is reported to have been plunged into a serious state of nervous prostration through the indiscretion of a "cheirosophist" who announced the fact of an abrupt break in her "line of life" and assured her that she would certainly die within three months. Palmistry, like some other fads, seems to have a double edge which it doesn't do to fool with.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, DECEMBER 16, 1886.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES, UPHAM & COMPANY,
283 WASHINGTON STREET, BOSTON, MASS.

MEDICAL NOTES.

— Dr. Joseph Schmidt, of Berlin, Germany, writes in the *Therapeutic Gazette* (November 15), of a case of lipoma of the size of a pigeon's egg and of eight years' duration, situated in the carotid region of a medical student of twenty-six years. Dr. Schmidt applied ichthyol with little expectation of its success in promoting absorption. A fifty per cent. solution of the ichthyo-sulphate of ammonium was rubbed into the part (the skin being previously washed with soap and water), three times daily for ten days. At the end of which time the lipoma had become converted into an abscess, which was evacuated and the sides and base of the capsule of the former lipoma were removed through the opening. In twelve days more the wound was entirely healed, and not the slightest trace of the swelling could be found.

NEW YORK.

— At the recent annual meeting of the Board of Managers of the State Charities Aid Association, Dr. Charles Hitchcock was elected Secretary.

— The first meeting of the Section on Public Health, Hygiene, and Legal Medicine of the New York Academy of Medicine, of which Dr. Alexander Hadden is Chairman, and Dr. Henry E. Crampton, Secretary, was held December 3d, when Dr. Blaine, of the Willard Insane Asylum, at Ovid, N. Y., read a paper on "Bovine Tuberculosis: its Communication by Inhalation, Ingestion, and Hereditary Transmission, and its Dangers to Public Health."

— Of the bust of Washington Irving, which Dr. Richard B. Wiener has presented to Central Park, Dr. John C. Peters, who was for a number of years Mr. Irving's physician, says that, as a likeness, it is better than anything extant, except the photograph from which it was made. He thinks, however, that many would have preferred that it should have represented him in the prime of life, as he was sixty-eight or seventy years of age at the time this photograph was taken.

— In a published appeal of the Annual Saturday and Sunday Hospital Collection, it is stated that, although the New York collection was unusually large last year, $5 was contributed in London for every $1 in New York.

— At the annual meeting of the New York Medico-Legal Society, held December 8th, at the Hotel Buckingham, Dr. Charles K. Mills read a paper on "Benjamin Rush"; and Dr. L. W. Baker, of Baldwinsville, Mass., read a paper on "Epilepsy and Forensic Medicine." The meeting was followed by the annual banquet, at which speeches were made by Dr. Charles K. Mills, of the Neurological Association; Johnson, of the New York County Medical; Dr. Gil Wylie, of Bellevue Alumni, and other prominent persons. Hon. Clark Bell was elected President, and Albert Bach, Esq., Secretary of the Society.

— Dr. Henry Slack died at his residence at Fishkill-on-the-Hudson, on the 10th of December, of renal and cardiac disease. He was born in Albany in 1831, and was graduated from Yale College in 1848, and the Albany Medical College in 1851. He subsequently pursued a course of medical studies in Paris, and in 1856, began practice in New York City. During the late war he was a surgeon in the army, and in 1865, removed to Fishkill-on-the-Hudson, where he remained in active practice until a few months since, when failing health compelled him to retire. He was chiefly instrumental in founding the Highlands Hospital at Matteawan, a busy manufacturing village near his home, where his surgical experience gained in the army proved of great service. He was most highly esteemed throughout the community in which he lived, and leaves a widow and three children.

— Prof. Albert R. Leeds, of the Stevens Institute of Technology, at Hoboken, read a paper, November 29th, before the New York Academy of Sciences, on "Purification of Water-Supplies." He has recently visited Great Britain for the purpose of examining the supply of the various cities, and he gave a description of some of the more notable systems in use, those of Glasgow, Leeds, and London being mentioned as among the best. He spoke of the different methods by which purification of water could be accomplished, the oldest, and one of the best of these methods, both as to safety and cheapness, being that by boiling. The process of boiling, however, while it destroyed organisms, had the disadvantage of leaving other impurities, and, in addition, rendered the water unpalatable. In order to make it agreeable to the taste, it was necessary to filter it, and cool it with ice. Having referred to purification by distillation, he described at length the method of oxygenizing large water-supplies by forcing oxygen through the mains, a process of essentially American origin. Professor Leeds gave several illustrations of the successful application of this method to various reservoirs, the water of which had become offensive on account of the decayed vegetable matter or other impurities.

— Dr. John P. Gray, the distinguished Superintendent of the State Lunatic Asylum at Utica, died November 29th, of Bright's disease. Dr. Gray never fully recovered from the shock of his attempted assasination, in 1882, by an insane man named Reimshaw, just after his return from Washington, where he had been acting as chief medical adviser of the Government in the trial of Guiteau for the murder of President Garfield. He received a severe pistol-shot wound of the face, and this was a serious shock to his nervous system, as well as giving rise to persistent and intense neuralgia. A year ago, his friends became alarmed about his condition, and he was induced to spend the winter in Thomasville, Ga. He returned in the spring considerably benefited, but, his health soon giving way again, he went to Europe, where he remained until October. Dr. Gray was born in Centre County, Penn., in 1825, and graduated from Dickinson College, after which he studied medicine, and received the degree of M.D. from the Medical Department of the University of Pennsylvania in 1848. After serving as interne of the Pennsylvania Hospital, he received the appointment of third assistant physician of the New York State Lunatic Asylum at Utica. By 1853, he had risen to the position of first assistant physician and acting superintendent, when he was called to accept the appointment of medical superintendent of the Michigan State Lunatic Asylum. In the following year, however, he accepted the position of superintendent of the asylum at Utica, which he retained up to the time of his death. He became celebrated as an expert in insanity, and his opinion was sought in many noted murder and will cases. He was the editor of the *American Journal of Insanity*, and Professor of Psychological Medicine in Bellevue Hospital Medical College, as well as the Albany Medical College. In 1876, he was President of the Section on Mental Diseases of the International Medical Congress, at Philadelphia; and in 1884, he was elected the second President of the New York State Medical Association, delivering the annual address before the Association at its session in 1885. A widow and three children, one of whom, John P. Gray, Jr., is a physician, survive him. His funeral took place December 2d, at Utica, and was attended by many distinguished members of the profession.

Correspondence.

ARE ALL VENEREAL PATIENTS LIARS?

CAMBRIDGE, N. Y., December 8th, 1886.

MR. EDITOR,— To the editorial question propounded in the JOURNAL, December 2d, "Are all Venereal Patients Liars," I was ready promptly to answer, All *married* ones are. Last evening, however, a married man residing here came into my office saying, "Doctor, I've got the clap, I got it in the strangest way (I think) you ever heard of." I replied I had heard of many singular ways of contracting this disease. He said, "I presume you have heard of getting it from a privy-seat? By sleeping in a strange bed at

hotels and on steamboats?" He also mentioned several other of the *usual* (?) ways of getting it. On informing him I had heard of all these ways, he replied, "I did not get mine in any of these ways; mine was caught by sleeping with a woman of the town in Albany about ten days ago." I told him I had sometimes heard of single men contracting it in that way, but it certainly was, as he said, about the strangest way for a married man I ever heard of.

Very respectfully yours,
T. C. Wallace, M.D.

MILKY TUMORS OF THE AXILLA.

Roxbury (Boston), December 10, 1886.

Mr. Editor,— I find that Dr. Champney, of the Royal Medical and Chirurgical Society (as quoted by Dr. A. H. Johnson in the Journal of December 9, page 548), is mistaken in supposing that the cases of "axillary lump" reported by him are "described for the first time in his paper." Velpeau, "Diseases of the Breast," Sydenham Society's Translation, London, 1856, pages 233–235, cites five cases by Scarpa, Siebold, Moor, Lee, and Stanley (with references), which seem to have been quite similar to those described by Drs. Champney, Johnson, and Sinclair. Siebold's case, in particular, appears to have been the exact counterpart of Johnson's. There were two cysts, one in each axilla, coming on during pregnancy. These tumors were covered with wrinkled skin, like the flesh of a chicken, and, on being squeezed gave exit to genuine milk. After confinement, the exudation ceased by degrees, and the swellings soon after disappeared.

It would seem difficult to determine the exact nature of these tumors, pathologically, without a minute examination of the solid structures in which the fluid is formed.

Yours respectfully,
Edward T. Williams, M.D.

SEVERED DIGITS.

South Paris, Maine, December 13, 1886.

Mr. Editor,— The reunion of severed digits is becoming a matter of considerable interest. I have a case it might be well to place among the others already reported. Some nine years ago, I was called to ride about one-half mile to see a little boy of seven years. Twenty to twenty-five minutes before my arrival he was in the wood-shed, and very generously holding small sticks upon the chopping-block for a sister a year or so younger, to cut with a rather heavy ax. The ax came down too near the hand, and severed the forefinger of the left hand, just *above* the second joint. The cut was made square and complete, the severed end falling among the chips, where I found it about twenty-five minutes later. Warmed it fully in warm water; adjusted it with great care; took two stitches, strapped and splinted carefully. Two years afterwards, it puzzled me to tell which forefinger had been cut. The merest trace of a scar was found. The action of the joint was perfect, the finger was well nourished, the muscles apparently as strong as those of the other forefinger, and the little fellow would not acknowledge there was any numbness. Yours very truly,

O. N. Bradbury, M.D.

Deaths reported 1,906: under five years of age 703: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 380, lung diseases 343, consumption 243, diphtheria and croup 169, measles 83, typhoid fever 39, diarrhœal diseases 35, malarial fever 22, scarlet fever 12, erysipelas 4, cerebro-spinal meningitis five, whooping-cough eight, puerperal fever three. From diarrhœal diseases, New York 15, Boston eight, Brooklyn four, Nashville three, Pittsburgh two, District of Columbia, Charleston and Fall River one each. From malarial fevers, New York and Brooklyn seven each, Baltimore four, District of Columbia, Nashville, Charleston and New Bedford, one each. From scarlet fever, New York five, Cincinnati three, Pittsburgh two, Brooklyn and Nashville one each. From whooping-cough, Brooklyn three, New York and Nashville two each, Boston one. From cerebro-spinal meningitis, New York four, Cincinnati one. From erysipelas, Cincinnati two, Brooklyn and Pittsburgh one each. From puerperal fever, Cincinnati two, Pittsburgh one.

In the 19 cities and greater towns of Massachusetts, with a population of 971,806 (population of the State 1,941,465), the total death-rate for the week was 18.14 against 19.03 and 16.64 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,093,817, for the week ending November 13th the death-rate was 19.1. Deaths reported 3,329: infants under one year of age 866; acute diseases of the respiratory organs (London) 346, measles 103, scarlet fever 39, fever 54, diarrhœa 62, whooping-cough 49, diphtheria 39.

The death-rates ranged from 13.8 in Portsmouth to 27.1 in Leeds; Birmingham 15.9; Blackburn 26.4; Hull 18 3; Leicester 19.4; Liverpool 20.5; London 17.4; Manchester 24.4; Nottingham 16.8; Sheffield 20.8; Sunderland 19.2.

In Edinburgh 19.5; Glasgow 23.8; Dublin 24.5.

For the week ending November 20th, in the Swiss towns, there were 26 deaths from consumption, lung diseases 17, diarrhœal diseases 10, whooping-cough four, typhoid fever three, diphtheria and croup two.

The death-rates were: at Zurich 5.7; Geneva 19.2; Basle 17.0; Berne 19.3.

The meteorological record for the week ending December 4, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps: —

Week ending	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 4, 1886, TO DECEMBER 10, 1886.

WOODHULL, A. A., major and surgeon. Ordered for duty at post of Fort Leavenworth, Kan. S. O. 138, Department of Missouri, December 3, 1886.

AINSWORTH, F. C., captain and assistant surgeon. Will repair to this city and report in person to the Secretary of War, and on completion of the duty which may be required of him will return to his station (New York city). S. O. 280, A. G. O., December 3, 1886.

AINSWORTH, FRED. C., captain and assistant surgeon. Relieved from duty as Recorder of the Army Medical Examining Board (New York city), and ordered to report in person to the Surgeon General of the army for duty in his office. S. O. 282, A. G. O., December 6, 1886,

BROWN, P. R., captain and assistant surgeon. Leave of absence for seven days, granted by post orders, is extended twenty-three days. S. O. 124, Department of Arizona, November 24, 1886.

TURRILL, H. S., captain and assistant surgeon. Ordered for duty as post surgeon, Fort Spokane, Wash. Ter. S. O. 209, Department of Columbia, November 29, 1886.

CARTER, EDWARD C., captain and assistant surgeon. Leave of absence extended six months. S. O. 281, A. G. O., December 4, 1886.

CLENDENIN, PAUL, first lieutenant and assistant surgeon. Assigned to duty at Fort Davis, Tex. S. O. 166, Department of Texas, November 29, 1886.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING DECEMBER 11, 1886.

PERCY, H. T., passed assistant surgeon. Ordered to Naval Academy, Annapolis, Md.

NORFLEET, ERNEST, passed assistant surgeon. Granted three months' sick leave.

BOOKS AND PAMPHLETS RECEIVED.

Transactions of the Minnesota State Medical Society 1886. St. Paul: H. M. Smyth Printing Co. 1886.

Inter-State Notification: its Principles as Demonstrated in the History of Yellow Fever at Biloxi, Harrison County, Miss, 1886.

Report on Experiments in Trap Siphonage at the Museum of Hygiene, United States Navy Department, Washington, D. C. By Glenn Brown. Washington: Judd & Detweiler. 1886.

The Differential Diagnosis of Scrotal Tumors. By D. A. K. Steele, M.D., Professor of Orthopædie Surgery in the College of Physicians and Surgeons of Chicago. Chicago: (Reprint.)

Report on the Purity of Ice from Onondaga Lake, the Erie Canal at Syracuse, and from Cazenovia Lake, to the State Board of Health of New York. By James T. Gardner, Esq., Consulting Engineer.

Ueber die manuelle Entwicklung des nachfolgenden Kopfes bei räumlichem Missverhältniss. (Nach einem in der Gesellschaft für Geburtshülfe und Gynäkologie zu Berlin gehaltenen Vortrag.) Von A. Martin. (Separat-Abdr. aus Berliner klin. Wochenschr., 1886, No. 40).

Moral Insanity: a Plea for a more exact Cerebral Pathology. By James Hendrie Lloyd, A.M., M.D., Instructor in Electro-Therapeutics in the University of Pennsylvania. A Thesis for Admission into the American Neurological Association, read at its Annual meeting at Long Branch, N. J., July 21-23, 1886. (Reprint.)

Two Papers. By W. H. Daly, M.D., Pittsburgh, Pa. Senior Physician to the Western Pennsylvania Hospital; Senior Physician for Diseases of the Nose, Throat and Chest to the Pittsburgh Free Dispensary; Ex-President of the Allegheny County Medical Society: General Surgeon to the Pittsburgh and Lake Erie Railroad Company; President of the Section of Laryngology of the Ninth International Medical Congress, Washington, D.C., 1887; Member of the British Medical Association, etc. I. Laryngology and its Cognate Branches in America. Read in the Section of Laryngology at the Eighth International Congress, at Copenhagen, Denmark, August, 1884. II. The Simplest and Most Efficient Treatment of Diphtheria. Read before the American Laryngological Association, at its Eighth Annual Congress, Philadelphia, 1886.

Lecture.

SCIENTIFIC MEN AND THEIR DUTIES.[1]

BY JOHN S. BILLINGS, M.D., LL.D., (HARV.), *Surgeon U. S. A.*

I do not believe that Government should undertake scientific work merely or mainly because it is scientific, or because some useful results may possibly be obtained from it. It should do, or cause to be done, such scientific work as is needful for its own information and guidance when such work cannot be done, or cannot be done so cheaply or conveniently by private enterprise. Some kinds of work it can best have done by private contracts, and not by officials; others, by its own officers. To this last class belong those branches of scientific investigation, or the means of promoting them, which require long-continued labor and expenditure on a uniform plan — such as the work of the Government Observatory, of the Government surveys, of the collection of the statistics which are so much needed for legislative guidance, and in which we are at present so deficient, the formation of museums and libraries, and so forth.

Considering the plans and operations of these Government institutions from the point of view of the scientific public, it is highly desirable that they should contribute to the advancement of abstract science, as well as to the special practical ends for which they have been instituted; but from the point of view of the legislator, who has the responsibility of granting the funds for their support, the practical results should receive the chief consideration, and therefore they should be the chief consideration on the part of those who are to administer these trusts. It must be borne in mind that while the average legislator is, in many cases, not qualified to judge *a priori* as to what practical results may be expected from a given plan for scientific work, he is, nevertheless, the court which is to decide the question according to the best evidence which he can get, or, rather, which is brought before him, and it is no unimportant part of the duty of those who are experts in these matters to furnish such evidence.

But in saying that practical results should be the chief consideration of the Government and of its legislative and adminstrative agents, it is not meant that these should be the only considerations. In the carrying out of any extensive piece of work which involves the collection of data, experimental inquiry, or the application of scientific results under new conditions, there is more or less opportunity to increase knowledge at the same time and with comparatively little increased cost. Such opportunity should be taken advantage of, and is also a proper subsidiary reason for adopting one plan of work in preference to another, or for selecting for appointment persons qualified not only to do the particular work which is the main object, but also for other allied work of a more purely scientific character.

On the same principle it seems to me proper and expedient that when permanent Government employees have at times not enough to do in their own departments, and can be usefully employed in scientific work, it is quite legitimate and proper to thus make use of them. For example, it is desirable that this country should have such an organization of its Army and Navy as will permit of rapid expansion when the necessity arises, and this requires that more officers shall be educated and kept in the service than are needed for military and naval duty in time of peace. It has been the policy of the Government to employ some of these officers in work connected with other departments, and especially in work which requires such special training, scientific or administrative, or both, as such officers possess. To this objections are raised, which may be summed up as follows:

First, that such officers ought not to be given posisions which would otherwise be filled by civilian scientists, because these places are more needed by the civilians as a means of earning subsistence, and because it tends to increase the competition for places and to lower salaries. Put in other words, the argument is that it is injurious to the interests of scientific men, taken as a body, that the Government should employ in investigations of work requiring special knowledge and skill men who have been educated and trained at its expense, and who are permanently employed and paid by it. This is analogous to the trades union and the anti-convict labor platform.

The second objection is that Army and Navy officers do not, as a rule, possess the scientific and technical knowledge to properly perform duties lying outside of the sphere of the work for which they have been educated, and that they employ as subordinates really skilled scientific men, who make the plans and do most of the work, but do not receive proper credit for it. The reply to this is that it is a question of fact in each particular case, and that if the officer is able to select and employ good men to prepare the plans and to do the work, this in itself is a very good reason for giving him the duty of such selection and employment.

A third objection is that when an officer of the Army or Navy is detailed for scientific or other special work, the interests of this work and of the public are too often made subordinate to the interests of the naval or military service, more especially in the matter of change of station. For example, civil engineers object to the policy of placing river and harbor improvements in the hands of Army engineers, because one of the objects kept in view by the War Department in making details for this purpose is to vary the duty of the individual officer from time to time so as to give him a wider experience. Hence it may happen that an officer placed on duty in connection with the improvement of certain harbors on the Great Lakes shall, after three or four years, and just as he has gained sufficient experience of the peculiarities of lake work to make his supervision there peculiarly valuable, be transferred to work on the improvement of the Lower Mississippi with which he may be quite unfamiliar.

In like manner Professor Clarke objects to having a laboratory connected with the medical department of the Navy on the ground that the officer in charge is changed every three years; consequently science suffers in order that naval routine may be preserved.

There is force in this class of objections, but the moral I should draw from them is, not that Army and Navy officers should not be allowed to do work outside their own departments or in science, but that when they are put upon such duty, the ordinary routine of change of station every three or four years should not be enforced upon them without careful con-

[1] President's address before the Philosophical Society of Washington, D. C., December 4th, 1886. (Concluded from page 565.)

sideration of the circumstances of the case, and satisfactory evidence that the work on which they are engaged will not suffer by the change. And, as a matter of fact, I believe this has been the policy pursued, and instances could be given where an officer has been kept twenty years at one station for this very reason.

I pass over a number of objections that I have heard made to the employment of Army and Navy officers as administrators, on the ground that they are too "bumptious," or "domineering," or "supercilious," or "finicky," because every one knows what these mean and their force. An Army officer is not necessarily a polished gentleman; neither is a civilian; and a good organizer and administrator, whether officer or civilian, will, at times, and especially to some people, appear arbitrary and dictatorial.

There is another objection to special details of Army or Navy officers for scientific duties which comes not so much from outside persons as from the War Department and the officers themselves, and it is this: Among such officers there are always a certain number who not only prefer special details to routine duty, but who actively seek for such details, who are perpetual candidates for them.

The proportion of men whose ideas as to their own scientific acquirements, merits, and claims to attention are excessive as compared with the ideas of their acquaintances on the same points is not greater in the Army than elsewhere, but when an Army officer is afflicted in this way the attack is sometimes very severe, and the so-called influence which he brings to bear may cause a good deal of annoyance to the Department, even if it be not sufficient to obtain his ends. I have heard officers of high rank, in a fit of impatience under such circumstances, express a most hearty and emphatic wish that no special details were possible, so that lobbying for them should be useless. This, however, seems to me to be too heroic a remedy for the disease, which, after all, only produces comparatively trifling irritation and discomfort.

The same evil exists, to a much greater extent, in the civil branches of the Government. Few persons can fully appreciate the loss of time, the worry, and the annoyance to which the responsible heads of some of our bureaus for scientific work are subjected through the desire of people for official position and for maintenance by the Government. They have to stand always at the bat and protect their wickets from the balls which are bowled at them in every direction, even from behind by some of their own subordinates.

It is true that a great majority of the balls go wide and cause little trouble, and a majority of the bowlers soon get tired and leave the field, but there are generally a few persistent ones who gradually acquire no small degree of skill in discovering the weak or unguarded points, and succeed in making things lively for a time. Considered from the point of view of the public interests, such men are useful, for although they cause some loss of valuable time, and occasionally do a little damage by promoting hostile legislation, yet their criticisms are often worth taking into account; they tend to prevent the machine from getting into a rut, and they promote activity and attention to business on the part of administrative chiefs. It is a saying among dog fanciers that a few fleas on a dog are good for him rather than otherwise, as they compel him to take some exercise under any circumstances.

At all events I think it very doubtful whether the jealousies and desire for position for one's self or one's friends which exist under present circumstances would be materially diminished under any other form of organization, even under a department of science.

Some conflict of interests now exists it is true; some work is duplicated; but neither the conflict nor the duplication are necessarily wholly evil in themselves, nor in so far as they are evil are they necessary parts of the present system. This system is of the nature of a growth; it is organic, and not a mere pudding-stone aggregation of heterogeneous materials, and the wise course is to correct improper bendings and twistings gradually, prune judiciously, and go slow in trying to secure radical changes lest death or permanent deformity result.

It will be seen that in what I have said I have not attempted to eulogize science or scientists in the abstract. I should be very sorry, however, to have given any one the impression that I think they should not be eulogized. Having read a number of eloquent tributes to their importance by way of inducing a proper frame of mind in which to prepare this address, it is possible that I overdid it a little, and was in a sort of reaction stage when I began to write. But the more I have thought on the subject, and the more carefully I have sought to analyze the motives and character of those of my acquaintances who are either engaged in scientific work or who wish to be considered as so doing, and to compare them with those who have no pretensions to science, and who make none, the more I have been convinced that upon the whole the eulogium is the proper thing to give, and that it is not wise to be critical as to the true inwardness of all that we see or hear.

At least nine-tenths of the praises which have been heaped upon scientific men as a body are thoroughly well deserved. Among them are to found a very large proportion of true gentlemen, larger, I think, than is to be found in any other class of men characterized by modesty, unselfishness, scrupulous honesty, and truthfulness, and by the full performance of their family and social duties.

Even their foibles may be likable. A little vanity or thirst for publicity, zeal in claiming priority of discovery, or undue wrath over the other scientist's theory, does not and should not detract from the esteem in which we hold them. A very good way of viewing characteristics which we do not like is to bear in mind that different parts of the brain have different functions; that all of them cannot act at once, and that their tendencies are sometimes contradictory.

There are times when a scientific man does not think scientifically, when he does not want to so think, and possibly when it is best that he should not so think. There is wisdom in Sam. Lawson's remark that "Folks that are always telling you what they don't believe are sort o' stringy and dry. There ain't no 'sorption got out o' not believing nothing." At one time the emotional, at another the intellectual, side of the scientific man has the ascendency, and one must appeal from one state to the other. Were scientific thinking rigorously carried out to practical results in every-day life, there would be some very remarkable social changes, and perhaps some very disagreeable ones.

That scientific pursuits give great pleasure without reference to their utility, or to the fame or profit to

be derived from them; that they tend to make a man good company to himself and to bring him into pleasant association is certain; and that a man's own pleasure and happiness are things to be sought for in his work and companionship is also certain. If in this address I have ventured to hint that this may not be the only, nor even the most important, object in life, that one may be a scientific man, or even a man of science, and yet not be worthy of special reverence, because he may be at the same time an intensely selfish man, and even a vicious man, I hope that it is clearly understood that it is with no intention of depreciating the glory of science or the honor which is due to the large number of scientific gentlemen whom I see around me. A scientific gentleman — all praise to him who merits this title—it is the blue ribbon of our day.

We live in a fortunate time and place—in the early manhood of a mighty nation, and in its capital city, which every year makes more beautiful and richer in the treasures of science, literature, and art which all the keels of the sea and the iron roads of the land are bringing to it. Life implies death; growth presages decay; but we have good reason for hoping that for our country and our people the evil days are yet far off. Yet we may not rest and eat lotus; we may not devote our lives to our own pleasure, even though it be pleasure derived from scientific investigation. No man lives for himself alone; the scientific man should do so least of all. There never was a time when the world had more need of him, and there never was a time when more care was needful, lest his torch should prove a firebrand and destroy more than it illuminates.

The old creeds are quivering; shifting; changing like the colored flames on the surface of the Bessimer crucible. They are being analyzed, and accounted for, and toned down, and explained until many are doubting whether there is any solid substratum beneath, but the instincts which gave those creeds their influence is unchanged.

The religion and philosophies of the Orient seem to have little in common with modern science. The sage of the East did not try to climb the ladder of knowledge step by step. He sought a wisdom which he supposed far superior to all knowledge of earthly phenomena obtainable through the senses. The man of science of the West seeks knowledge by gradual accumulation, striving, by comparison and experiment, to eliminate the errors of individual observations, and doubting the possibility of attaining wisdom in any other way. The knowledge which he has, or seeks, is knowledge which may be acquired partly by individual effort, and partly by coöperation, which requires material resources for its development, the search for which may be organized and pursued through the help of others, which is analogous in some respects to property which may be used for power or pleasure. The theologian and the poet claim that there is a wisdom which is not acquired, but attained to, which cannot be communicated or received at pleasure, which comes in a way vaguely expressed by the words intuition or inspiration, which acts through and upon the emotional, rather than the intellectual faculties, and which, thus acting, is sometimes of irresistible power in exciting and directing the actions of individuals and of communities.

The answer of the modern biologist to the old Hebrew question, *viz.*, "Why are children born with their hands clenched, while men die with their hands wide open?" would not in the least resemble that given by the Rabbis, yet this last it is well that the scientist should also remember: "Because, on entering the world, men would grasp everything, but on leaving, it all slips away." There exist in men certain mental phenomena, the study of which is included in what is known as ethics, and which are usually assumed to depend upon what is called moral law. Whether there is such a law, and whether, if it exists, it can be logically deduced from observed facts in nature, or is only known as a special revelation, are questions upon which scientific men, in their present stage of development, are not agreed. There is not yet any satisfactory scientific basis for what is recognized as sound ethics and morality throughout the civilized world; these rest upon another foundation.

This procession, bearing its lights of all kinds — smoky torches, clear-burning lamps, farthing rushlights, and sputtering brimstone matches — passes through the few centuries of which we have a record, illuminating an area which varies, but which has been growing steadily larger. The individual members of the procession come from, and pass into, shadow and darkness, but the light of the stream remains. Yet it does not seem so much darkness, an infinite night, whence we come and whither we go, as a fog, which, at a little distance, obscures or hides all things, but which, nevertheless, gives the impression that there is light beyond and above it. In this fog we are living and groping, stumbling down blind alleys, only to find that there is no thoroughfare, getting lost, and circling about on our own tracks as on a jumbie prairie; but slowly and irregularly we do seem to be getting on, and to be establishing some points in the survey of the continent of our own ignorance.

In some directions, the man of science claims to lead the way; in others, the artist, the poet, the devotee. Far reaching as the speculations of the man of science may be, ranging from the constitution and nature of a universal protyle, through the building of a universe, to its resolution again into primal matter or modes of motion, he can frame no hypothesis which shall explain consciousness, nor has he any data for a formula which shall tell what becomes of the individual when he disappears in the all-surrounding mist. Does he go on seeking and learning in other ways or other worlds? The great mass of mankind think that they have some information bearing on these questions; but, if so, it is a part of the wisdom of the Orient, and not of the physical or natural science of the Occident. Whether, after death, there shall come increase of knowledge, with increase of desires, and of means of satisfying them, or whether there shall be freedom from all desire, and an end of coming and going, we do not know; nor is there any reason to suppose that it is a part of the plan of the universe that we should know. We do know that the great majority of men think that there are such things as right and duty — God and a future life — and that to each man there comes the opportunity of doing something which he and others recognize to be his duty. The scientific explanation of a part of the process by which this has been brought about, as by natural selection, heredity, education, progressive changes in this or that particular mass of brain-matter, has not much bearing on the practical question of "What to do about it?" But it does, nevertheless, indicate th... it is not a char-

acteristic to be denounced, or opposed, or neglected, since, even in the "struggle-for-existence" theory, it has been, and still is, of immense importance in human social development.

"Four men," says the Talmud, "entered Paradise. One beheld and died. One beheld and lost his senses. One destroyed the young plants. One only entered in peace and came out in peace." Many are the mystic and cabalistic interpretations which have been given of this saying; and if for "Paradise" we read "the world of knowledge," each of you can, no doubt, best interpret the parable for himself. Speaking to a body of scientific men, each of whom has, I hope, also certain unscientific beliefs, desires, hopes, and longings, I will only say: "Be strong and of a good courage." As scientific men, let us try to increase and diffuse knowledge; as men and citizens, let us try to be useful; and, in each capacity, let us do the work that comes to us honestly and thoroughly, and fear not the unknown future.

When we examine that wonderful series of wave-marks which we call the spectrum, we find, as we go downwards, that the vibrations become slower, the dark bands wider, until at last we reach a point where there seems to be no more movement; the blackness is continuous, the ray seems dead. Yet within this year, Langley has found that a very long way lower down, the pulsations again appear, and form, as it were, another spectrum; they never really ceased, but only changed in rhythm, requiring new apparatus or new senses to appreciate them. And it may well be that our human life is only the lower spectrum, and that beyond and above the broad, black band which we call death, there are other modes of impulses — another spectrum — which registers the ceaseless beats of waves from the great central fountain of force, the heart of the universe, in modes of existence of which we can but dimly dream.

FRACTURES OF THE LOWER END OF THE HUMERUS.[1]

BY J. S. BIGELOW, M.D., DUBUQUE, IOWA.

THE shaft of the humerus may be the seat of fracture in its upper, middle, or lower third, and there may be a variety of fractures of what is more properly termed the *lower end* of the humerus, and to these, owing to their frequency, and the imperfect results which often follow our best efforts at treatment, I wish to call particular attention. The lower portion of this bone, in children up to the tenth year, is broken more than twice as often as the other portions together, so that what I may say refers more particularly to children. The boundary line between the shaft and lower end is not well defined, being a surgical rather than an anatomical division. There are several different fractures of the lower end of this bone. It may be fractured more or less transversely just above the condyles, the line usually running from before backward and upward. One or more lines may extend downward into the joint; the outer portion, the epi-condyle or external condyle, as it is called, may alone be broken off; or the inner condyle may be separated, or the trochlear surface, that part which articulates with the ulna, may be broken, the other parts of the joint remaining in contact. Finally, there may be disjunction of the epiphysis or of its articular portion only. Where the articular portion only, is broken off, Prof. R. W. Smith terms it an infra-condyloid fracture. He claims that the line of junction between the epiphysis and shaft is below the condyles; that when separation of the epiphysis occurs, the condyles always remain above the line of separation and in connection with the shaft; hence the term infra-condyloid fracture. It is needless to say Professor Smith's description does not agree with the description of the ossification of the lower end of the humerus, as given by standard authors on anatomy, and accepted by surgeons generally. If we accept Professor Smith's description, we should say that, up to the eighteenth year, we may meet with two fractures of the lower end of the humerus; one lying above, and one lying below, the condyles. This variety of fractures may be enumerated theoretically, although they are not in practice so readily distinguishable; for frequently the lines of separation are very irregular, two or more varieties coexisting, or a dislocation may add to the difficulties of diagnosis. In any case in childhood where we find a transverse fracture of the lower end of the humerus, the question of separation of the epiphysis is apt to arise, and unless we are somewhat familiar with the anatomical structure and development of the parts, we are liable to error.

Development: The epiphysis consists of four parts. The radial portion of the articular surface commences to ossify at the end of the second year; and from this point extends in, so as to form the chief part of the articular end of the bone. The centre for the inner part of the articular surface appears at the age of twelve. Ossification commences in the internal condyle at about the fiftieth year, and in the external one about the age of thirteen or fourteen. At about the sixteenth or seventeenth year, the external condyle and the two portions of the articulating surface are joined together, and unite with the shaft: About a year later, that is at seventeen or eighteen, the inner condyle unites. Before these parts are united, we may have not only separation of the epiphysis, but either of the centres may become separated from the others, producing fracture of the internal or external condyle, or separation of the trochlea. A point of interest in connection with these fractures is the peculiar anatomical contour of the elbow-joint. The trochlear surface with which the ulna articulates, projects downwards at its inner margin considerably lower than any other portion of the bone. The result is, that when violence of any kind is brought to bear against the forearm, the lower end of the humerus is twisted off. Fractures of the lower end of this bone extend into the joint. Even when they do not, their close proximity to the joint often gives rise to extensive inflammation of the synovial membrane, producing effusion into its cavity, materially increasing the difficulties in recognizing the injury and embarrassing the treatment.

Causes. The causes of these fractures are, generally, falls on the hand or elbow. Frequently this bone is broken by muscular action alone. The deformity is variously modified by the manner of receiving the injury.

[1] Read before the Cedar Valley Medical Society of Iowa.

Symptoms. The symptoms may be obscure: extensive swelling generally sets in early, hence the sooner we see the case and determine correctly the difficulty the better. The upper fragment is generally in front of the lower, due partly to muscular action, partly to the direction of the line of fracture, and partly to the fracturing force, driving the elbow backward. The lower fragment tilts forward. The antero-posterior diameter just above the elbow is increased. Pain is nearly always present. Mobility is generally increased; where the parts are pretty freely separated into the joint, the motion is very free, imparting a loose, rattling sensation when the forearm is rotated. When there is lateral motion a fracture is certain, for there is absolutely no lateral motion in a sound elbow-joint. Luxation does not free the joint in any way. When the arm hangs by the side completely extended, palm forward, the elbow forms a very obtuse angle laterally, the forearm being directed downward and considerably outward. This is due to the trochlear portion of the lower articular surface of the humerus, slanting outward and being longer than the caputellum with which the radius articulates.

If the forearm be fully flexed without any rotation of the humerus, the hand comes up to the outer side of the shoulder joint so far, that with the utmost pronation and flexion of the wrist, the middle finger cannot be brought opposite the mouth. These facts are of importance in the recognition and treatment of fractures in this region. Disjunction of the epiphysis can happen only in childhood or youth. A portion of the bone may be torn off with the epiphysis, or on the other hand the fracture may concern a portion only of the epiphysis, and thus be entirely within the joint. When the fracture is thus low down, there is no perceptible deformity, though there is distinct crepitus. The course and ultimate results of fractures of the lower end of the humerus are apt to be unsatisfactory. A certain amount of stiffening of the elbow-joint is almost always induced, which, as a rule, disappears if the fragments have been replaced in their normal position. The bloodvessels seldom suffer, except in some compound fractures where they may be torn across. Sometimes the circulation may be interfered with by badly applied splints. Wright records a case where an anterior angular splint occluded the main artery for twenty days, and says no permanent harm resulted. Occasionally, serious harm is done to nerves. The musculo-spiral, ulnar, and median nerve, each is at times injured. The ulnar nerve lies very close to the internal condyle, and would seem to be in constant danger. When the posterior interosseous branch of the musculo-spiral or the main trunk itself is injured, a peculiar form of wrist-drop is produced, due to partial or complete paralysis of the supinator and extensor muscles. As a rule, these paralyses improve after a time, still there may be instances where the loss of power is permanent.

The diagnosis in some of these cases of fracture presents no difficulties, in other cases it may be exceedingly obscure. In any doubtful case an anæsthetic should be given, and passive motion resorted to. As a rule, these fractures resemble a backward dislocation of the ulna. In case of fracture, the surgeon can place his thumbs in front of the projection and push the olecranon forward to its place, and easily keep it there until he relaxes his hold. Dislocations are difficult to reduce; but when reduced generally remain in place when the effort is relaxed. The condyles should be located, as they can be, even when swelling is present; and pressure made upon them. If pain is increased, a fracture running into the joint may be suspected; if crepitus is produced a fracture may be regarded as certain. There should be no lateral motion of the forearm, any such motion found establishes a fracture with certainty. Increase in the width of the elbow may be regarded as probably due to fracture involving the joint. These are some of the prominent points on which we must make our diagnosis; but in practice there are shades of difference in the appearances presented, which it would be useless to attempt to describe. We may sum up by saying that fractures and other injuries at the elbow-joint demand more care, tact and judgment for their detection and treatment, than those of any other part of the body.

Prognosis. The elbow is apt to be stiffened after injuries in its neighborhood, so that it is always well to warn friends of what the result may be. All surgeons caution us to warn our patients of what the result may be. This universal warning in regard to fractures at the elbow-joint necessarily implies imperfect results in our treatment of them. The purpose of this paper is, if possible, to offer a method of treatment which will give better results than by the old method of dressing the arm in the flexed position. If the line of fracture is clearly above the epiphysis, the prospects for complete recovery are much more promising; still a very slight tilting of the lower fragment forward, which is so liable to occur, will give rise to some permanent limitation of motion, which cannot be remedied by any treatment, as can be done in mere stiffening of the joint produced by effusion of inflammatory material.

Treatment. The difficulties in the treatment of these fractures are: to keep the fragments in contact and at rest; to prevent the formation of an angle slanting forward; to maintain the oblique line of articulation at the elbow, by avoiding upward pressure on the inner portion of the joint surface of the lower fragment; and to avoid stiffening of the elbow-joint. In order to avoid stiffening, no matter what method of treatment is employed, passive motion must be resorted to. Holmes, Vol. I, says passive motion should be commenced in about three weeks, and quotes Sir Astley Cooper as advocating passive motion to be instituted at the expiration of three weeks after the injury in children, and at a month in adults, and says further that this practice has been followed by most English surgeons. Malgaigne[1] moved the joint on the twentieth day. Erichsen says passive motion should be had recourse to at the end of three weeks in children and in four or five weeks in adults. Dr. Hamilton[1] strongly advised that passive motion be begun within seven days and perhaps earlier, and perseveringly employed from day to day until the cure was accomplished. Dr. Allis, of Philadelphia, condemns early passive motion. He maintains immobility in the extended position until consolidation has taken place, never using passive motion under any circumstances earlier than the fourth week. He says in the milder and middle grades he never has any trouble with functional returns, while in the severer grades there is great injustice done the medical profession, as well as to the patient, by intimating that any course whatever would have insured a prompt return to usefulness.

[1] Holmes, Vol. 1, p. 868.

The difficulty of keeping the fragments in contact and at rest is due to the shortness of the lower fragment, which gives no purchase to any kind of dressing. No matter what kind of an angular splint we apply, the hand and forearm are converted into a powerful bent lever, upon which a very slight amount of force acts most powerfully in loosening the bandages and disturbing the parts above the elbow. We dare not bind on the splints too tightly, as by so doing we endanger the vascular supply to the parts. After a few days, when swelling begins to subside, the constant tendency is for the bandages to become loosened, so that the controlling power of the apparatus is lost.

The difficulty of maintaining the *normal lateral angle* of the forearm upon the arm seems to be frequently overlooked. Any dressings or appliances which push the trochlear surface upward, at the same time push the upper inner angle of the lower fragment past the corresponding portion of the upper fragment, either in front or behind it, and thus destroy the normal lateral angle of the arm.

The general methods of treatment are three: First, and most commonly by apparatus for maintaining the arm in flexion; second, by apparatus for keeping the arm extended; third, without any apparatus, the principle of treatment being to suspend the limb in a sling in the flexed position, changing the angle from time to time in order to prevent anchylosis, the point in this method being that it is better to have a false joint than to have union with anchylosis. Some surgeons of large experience do not consider a false joint near the elbow as a misfortune, but, on the other hand, advocate that method of treatment, having in view the production of such a result. You are no doubt all familiar with the general method of treating these fractures, namely, that of flexing the forearm to about a right angle, and using the old rectangular splint. This method, with some slight modifications of the splint, has been recommended by nearly all surgeons, but these slight modifications of the splint do not change the principle underlying this method, so I think I need not dwell on its description.

The method of using a long straight splint, keeping the arm extended same as in fracture of the olecranon, has not come into general use. Dr. Allis, of Philadelphia, Pa., first described it, and it is therefore termed Allis's method. Dr. McCluer, of Dubuque, deploring his imperfect results in the treatment of these fractures by the old method, began treating them in the extended position as long ago as 1870. The results proving highly satisfactory, he has continued to use and recommend this method. Among the other physicians of Dubuque who have used and are using this method may be mentioned Drs. M. H. Waples and William Watson, the latter of whom is very enthusiastic in its favor, having used it for a number of years past. Dr. Ingalls, in an article in the *Medical News* for January 7, 1882, states that he uses this method for treating all fractures about the elbow-joint that are treated in the Boston City Hospital.

I think this method of treatment fulfils some indications not met by the rectangular splint. First, the normal lateral angle of the arm can be absolutely and perfectly maintained. Second, the arm being dressed extended, has less of a leverage in loosening the bandages and disturbing the parts than when flexed, the forearm and hand then acting as a powerful bent lever, the slightest motion of which must produce more or less disturbance either at the elbow-joint or at the seat of fracture. Third, when dressed in the extended position, the surgeon has better control over the lower fragment. When dressed in the flexed position, the constant tendency of this fragment is to tilt forward and produce a deformity common to these fractures, namely, an angle slanting forward just above the joint. This tendency is avoided by dressing the arm straight. The powerful muscles above the elbow, namely, the biceps and brachialis anticus in front, and the triceps behind, do not produce tilting of the lower fragment one way or the other. They are not attached to this fragment at any point. Their attachments are to the radius and ulna exclusively. These powerful muscles might indirectly produce this deformity by their action, in shortening the humerus, and thus causing an overlapping of the fractured ends, but since we find tilting forward of the fragments in many cases where the fracture is transverse, and the fragments do not overlap, there must be some other agent more constant and more direct in its action in producing this deformity than the muscles above mentioned.

The superficial flexors of the forearm and the pronator radii teres take their origin from the internal condyle and supra condyloid ridge; the superficial extensors and the supinator longus arise from the external condyle and supra condyloid ridge. The pronator radii teres is inserted into a rough ridge at the middle of the outer surface of the radius. The flexor carpi ulnaris is inserted into the pisiform bone — annular ligament and metacarpal bone of little finger. The flexor carpi radialis is inserted into the base of the metacarpal bone of the index finger. The supinator longus into styloid process of radius. The extensor carpi radialis longior and brevior, the extensor communis digitorum, extensor minimi digiti and extensor carpi ulnaris all arise from the external condyle and supra condyloid ridge, and are inserted in a similar manner to the annular ligament and carpal and metacarpal bones.

To illustrate their action in producing displacement of the lower fragment in fractures of the lower end of the humerus we will suppose them all to be attached or inserted into the annular ligament of the wrist joint. When the forearm is brought to a right angle with the arm, the position in which we are taught to dress it after a fracture of the lower end of the humerus, the effect of contraction of the muscles just described is to tilt the upper end of the lower fragment forward. The action of these muscles is reversed. Their point of origin, at the condyles, the fixed point, now becomes their point of insertion, the movable point, and their normal point of insertion, which we have for convenience made to the annular ligament of the wrist, which part they naturally move by their contraction, now becomes the fixed point, the point of origin. Their attachment to the condyles and supra condyloid ridges is above the centre of motion at the elbow-joint. The result is, that when we flex the forearm, and apply the angular splint recommended by nearly all surgeons, the tonic contraction of these muscles produces a deformity which, however slight, will prevent full flexion of the arm.

When the arm is dressed in the flexed position, I see no reason why the superficial extensors may not assist in producing the deformities just mentioned. Their point of attachment to the external condyle and

supra condyloid ridge is above the centre of motion at the elbow-joint, similar to that of the flexors. As soon as the shortest direct line between their point of origin and insertion came in front of the centre of motion at the elbow-joint, their action as extensors would cease. They would then virtually be flexors, and assist in producing the same deformity as that produced by the flexors.

Professor Packard, of Philadelphia, says the method of putting the arm in extension, with the normal lateral angle maintained, and keeping the limb in this posture by means of some immovable apparatus, is a very sound one in theory, and no doubt has given good results. But he thinks the same results may be attained in the flexed position, and with more comfort to the patient. I think I state without fear of contradiction that it is very difficult, or next to impossible, to know whether we have the arm at the proper angle when in the flexed position, and as to the comfort of the patient, I think no method can surpass the extended position. The experience of the surgeons who have used this is that when dressed the patient is perfectly comfortable. A patient with the arm extended and the lateral angle perfectly maintained by one or two straight splints, goes about with the arm hanging by the side, or supported with the other hand, complaining of no pain whatever.

The results of this method of treatment by the surgeons whom I have mentioned have been perfect in every instance. My own observations are limited to four cases, three children and one adult, with perfect results in each case. In consideration of these encouraging results, I think I will be sustained by all who have used this method, in making the broad statement that where the same care, tact, and judgment are used in dressing these fractures in the extended position as are used in dressing them in the flexed position, the results in the former will be better. I would therefore recommend this method of treatment to those who have had imperfect results in the treatment of these fractures by the old method.

TWO CASES OF LABOR COMPLICATED WITH FIBROID TUMORS, WITH REMARKS.[1]

BY W. E. BOARDMAN, M.D.

Case I. Nora C., octopara, was admitted to the Boston Lying-in Hospital during my service, August 1st, 1882, at the request of her attending physician, with the view of having labor induced artificially, on account of the presence of a fibroid tumor which, it was feared, would become a serious complication to the process of labor if pregnancy was allowed to continue until the full term. She was then in the seventh month of pregnancy.

Upon examination after admission, there was found a sessile, interstitial, or rather submucous tumor the size of a fœtal head, in the anterior wall and projecting within the cavity throughout its whole extent, apparently, or at least as far as the examination permitted its exploration, and soft to the touch. The fœtus appeared to be small, though living. The os was patulous, and readily admitted two fingers, so that the tumor could be reached.

[1] Read before the Suffolk District Medical Society, Section for Obstetrics and Gynæcology, Nov. 17, 1886.

Upon consultation it was decided, in the interest of the child, to postpone interference as long as possible, consistent with due regard for the safety of the mother. On the following day, however, at 11 A.M., labor began, the breech presenting, and was completed at 5 A.M. on the next day, without any abnormal incident. The child was stillborn. The following brief extracts from the records are given to illustrate the subsequent history of the case:

August 4th, the day after delivery, A.M. pulse 100, temperature 101.7°, and P.M. pulse 104, temperature 103.5.° Following the custom then prevailing in the hospital, vaginal carbolized douches were given, and also ergot and quinine were administered. The patient continued to be nervous and weak, slept and ate poorly. The pulse and temperature varied but little from day to day until August 7th, when the record states the A.M. pulse 68, temperature 98.3°, P.M. pulse 78, temperature 102.2°, and the lochial discharge became very offensive. The pulse and temperature again rose, and on August 9th, A.M. pulse 104, temperature 101.2°, when, upon examination, the tumor was found to be protruding from the external os. Gradually it came down so as to occupy the vaginal cavity, and on the 13th, the general symptoms became so threatening that, during my absence from the city, Dr. Richardson was summoned, and he removed the entire mass, which was exceedingly foul, and thoroughly cleansed the uterine and vaginal cavities. On the following day, peritonitis developed, and shortly after collapse occurred, and death ensued.

Case II. During my service in January, 1886, N. M., single, primipara, was admitted to the hospital. She stated that, having previously menstruated every two weeks, she was exposed in July, since which time the catamenia had not appeared. About this time she began to suffer with abdominal pains, to relieve which she soon contracted the opium habit, and shortly after consulted Dr. C. P. Strong in regard to some "lumps" in the abdominal cavity. He diagnosticated multiple fibroids, but declined to consider the subject of operation for their removal, chiefly because he suspected associated pregnancy, which subsequent observation proved to be the condition.

January 21st, she complained of symptoms which pointed to the coming on of labor, and, by his advice, she was sent to the hospital on the following day, when, upon examination, a very loud and distinct souffle over the whole lower abdomen, but no fœtal heart, could be heard. By palpation the fundus was felt, reaching just above the umbilicus, irregular in outline. Upon either side of this were several fibroid masses. Per vaginum there was found a retro-vaginal fibroid mass, which filled posteriorly the excavation, obviously with a high attachment to the uterus, and could not be dislodged by pressure with the fingers. In front, and very high up, behind the symphisis, the cervix was found, with the os soft and patulous, admitting more than the finger tip, and the posterior lip notably elongated. It was decided to wait until the pains should become more frequent and regular, in order to ascertain what nature would accomplish before attempting interference in any way. During the day, January 22d, it was found that the cervix gradually came down lower in the pelvis, though to a slight degree, and the fœtal heart could be heard, but not counted at the right of and below the umbilicus.

On the following day, in the morning, the pains

became nearly constant, but slight, the cervix was taken up; the os, the size of a twenty-five cent piece, was easily reached, and found distended by a fluctuating tumor. The membranes obviously had ruptured at 12 M., on the day before. The os continued to dilate gradually but slowly until 3 P.M., when it was fully dilated, and the fluctuating tumor, which was then recognized as an encephalocele, presented at the vulva. In the meantime, the retro-vaginal fibroid had gradually ascended until finally it was entirely above the brim. Soon after this the child was born, having been delayed somewhat in the passage of the head beneath the pubic arch. The fœtus was stillborn. The uterus contracted firmly after the expulsion of the placenta and there was no hæmorrhage. Convalescence was uninterrupted, and she left the hospital February 4th. Upon examination before her departure, the cervix was found to be lacerated bilaterally, and the uterus was anteverted and lying prone beneath the mass of fibroids.

In connection with the relation of these cases it may not be out of place to give a brief *résumé* of our present knowledge concerning fibroid tumors in their relation to conception, pregnancy, parturition, and the post-partum period. It is a well-recognized fact that these tumors predispose to sterility, the subserous variety primarily on account of the uterine displacements which they induce, the interstitial for the same reason, and, if these tend to become the third variety, or submucous, on account of the changes which they induce in the lining membrane of the uterus, and which lead to hæmorrhage and other discharges that ordinarily prevent conception. Still sterility is by no means the absolute rule with either variety, and especially is this true of the subserous form. Another fact is observed, which is notably true of the submucous variety, but not confined to this class, that abortion or premature labor is likely to ensue.

In some cases, however, pregnancy is uninterrupted until the period of normal labor arrives. Meanwhile, it is the common observation that during pregnancy these tumors develop rapidly, and, as a rule, undergo a change in consistence, becoming softer, and at times are transformed more or less into colloid or cystic masses. It is a frequent occurrence, too, that abnormal positions and presentations of the fœtus are occasioned by all varieties of these tumors, and it may be added there appears to be a notable disposition, with the interstitial and submucous varieties, to placenta prævia, or to the implantation of the placenta over the locality of the tumors.

At the time of labor, these tumors may or may not interfere with the normal processes of parturition, according, in the main, to the variety, to the size of the tumor or tumors, their location and mobility, to the existence and extent of adhesions, and to the period of pregnancy.

In the earlier months, the process of abortion or very premature birth very likely will not be complicated to an unusual degree, except, possibly, by hæmorrhage, which, however, ought not to become a source of danger in these cases.

In the later months, and at term, either variety may become a serious obstacle to delivery, and a source of danger either to the mother or to the child, or to both, and in various ways, of which the following will serve as illustrations:

Uterine fibrous polypi may be the occasion of hæmorrhage, or interfere with delivery, from occupying so much of the cavity of the body or cervix as to delay or prevent the passage of the fœtus, or from presenting in front of the fœtus.

Submucous fibroids, if situated above the body and in the fundus, will offer no impediment to delivery, except, perhaps, they occasion irregularity in the uterine contractions, or give rise to hæmorrhage. Situated in the body, however, from their size, which is increased largely during pregnancy, they commonly become a serious impediment, acting in a like manner with the polypi similarly situated.

Interstitial tumors obstruct delivery, as a rule, only when, in their rapid growth during pregnancy, they become more or less submucous in character, or are located in the body or cervix, and attain sufficient size to obstruct mechanically the progress of the fœtus. If they develop outwards, tending to become subserous, they commonly afford no serious obstacle, provided they remain, or can be kept above the brim of the pelvis. Similarly, too, extra-uterine or subserous, or subperitoneal tumors may not seriously complicate labor, provided they do not encroach upon the parturient canal to a degree which will prevent the passage of the fœtus.

If such a tumor is connected with the body of the uterus, and is not tied down by adhesions, the longitudinal contractions of the uterus will serve to elevate or keep it above the brim, but if it originates from the cervix, in some cases it will permanently occupy the pelvis, becoming retro-vaginal; and if it attains to a great size, it will afford an impassable barrier to the expulsion of the fœtus, constituting, in fact, a shortening of the pelvic diameters.

The treatment of these cases, in the light of comparatively recent experience, which has been based upon modern advances in gynæcological, obstetrical, and surgical practice, offers a very wide and interesting field for discussion, which the scope of this paper will not permit me to enter upon, except in a very brief manner.

There is a general consonance of opinion as to the treatment of the polypoid variety of tumors. During pregnancy, hæmorrhage sometimes becomes a dangerous symptom, and in these cases, the ordinary rules of surgical procedure should, and may safely be applied, and the tumor should be removed.

At the time of labor, the general practice is to await the proper dilatation of the os, and then, in the intervals between the pains, to push up the tumor, and allow succeeding pains to expel the presenting part in front of it. Failing in this attempt, or if the tumor already is pressed down in advance of the head, and is too large to admit of the passage of the child without endangering its life, or the mother's soft parts, the only proper method appears to be to remove the entire tumor by means of the ecraseur or the knife, if the pedicle can be reached; otherwise, as much of it as possible should be taken away. Fortunately, in these cases it is quite the rule, I believe, that the pedicle is within reach, attached to the cervix, or just above it. If the pedicle is very small and thin, nature, in her efforts to expel the child, would, without doubt in many cases, rupture the attachment, but at the expense of time and strength, which might be saved to the mother and child to their mutual advantage.

With the submucous variety of fibroids, including the interstitial forms, which, in their development

during pregnancy, tend to become submucous, the practice has been to await the results of nature's efforts, and when these have failed, to resort to some artificial means of delivery; and, as a rule, until lately the child has been sacrificed in the interests of the mother; but, as a rule, too, in these cases the mother has succumbed, sooner or later, to hæmorrhage, exhaustion, shock, or septicæmia.

Even in cases where there has been no serious impediment to delivery, the tumor, softened by the processes incident to its rapid growth during pregnancy, is subjected to so much pressure after the rupture of the membranes and by the uterine contractions, that sloughing and gangrene ensue, and the patient is overwhelmed with septicæmia or pyæmia, as, for instance, in the case which I have reported.

The older obstetric records furnish little but fatal results in these cases, when left to the natural efforts, or where craniotomy or Cæsarean section, either alone or combined, were performed. The study of the details of reported cases appears to disclose one salient fact, namely, that many, if not most, of the immediately fatal results have been due to delay; and bearing in mind that where delivery has, in a surgical sense, been safely accomplished, while the patient subsequently died with septicæmia, the deduction seems clear to me that the safety of both mother and child, in these cases, suggests the following methods of practice, namely: If the tumor is not so large as to offer a serious obstacle to delivery, I should avoid, as much as possible, the compression of it by manual or instrumental delivery directly after the rupture of the membrane, employing artificial dilatation of the os, if required.

In case the tumor is so large as to block the passage of the presenting part so as to form an impassable barrier and is accessible, it would seem to be the best practice, in suitable cases, to employ enucleation, as has been successfully done by Mundé of New York and others. With regard to a resort to version, forceps or craniotomy, similar rules apply as in cases of deformed pelvis, except that with fibroids we must, on the one hand, endeavor to appreciate with considerable accuracy their position, mobility and consistence, and, on the other, the liability to subsequent septicæmia, to which reference has already been made.

Whenever delivery appears to be impossible per *vias naturales*, either under nature's efforts alone or with the intelligent assistance of art, or when there is good reason to believe that these efforts will not only destroy the child, but very likely the mother also, respect for the obstetric art, and more than this, humanity, seems to me clearly to indicate an early resort to laparotomy in some of its forms.

In the light of modern success in abdominal surgery and from a critical study of the cases in recent years which have been the subjects of Cæsarean section, Porro's, Müller's, or Sänger's operations or of laparo-elytrotomy, it seems to me to be evident that the timely resort to one of these methods will, in the future, result in the saving of many maternal and fœtal lives.

If the tumors be interstitial, but tending to the subserous variety, it is probable that delivery will not be interfered with to any great extent, except from the delay sometimes occasioned by irregular contractions, provided the tumors are above the brim of the pelvis. The same is true in general of the subserous tumors.

In many cases, however, as in the second one I have related, there is a tumor occupying the retrovaginal space. If this be not too large or adherent, it may sometimes be pushed above the brim and held there until the fœtus engages or occupies the excavation. If this cannot be done, I believe the essential point to be determined, if possible, is whether the tumor has its origin in the body or above, or in the cervix of the uterus.

If the former is the case and it is not tied down by adhesions, the longitudinal contractions of the uterus will gradually lift it out of the pelvis, as occurred in the case reported, and in this effort nature may often be assisted, and labor will then go on without dangerous obstacles so far as the tumor is concerned. When, on the other hand, the tumor arises from the cervix the contractions are not sufficient to effect this result, and in this case similar rules will apply as with the submucous variety, that is to say, one ought to resort, if it seems necessary on account of the size of the tumor, to version, forceps or craniotomy, and in some of these cases the timely employment of laparo-elytrotomy, especially, would seem to be demanded with the view of affording the best chances to both mother and child, though it is to be kept in mind that with these subperitoneal tumors, while there is a liability to a subsequent peritonitis, there is not the danger of a supervening septicæmia so common after labor complicated with the submucous fibroids.

The question of the advisability of the induction of premature delivery in these cases is one of great importance and calls for the most careful scrutiny in each instance. The consistence of the tumors, their locality and mobility, their size and rate of development during pregnancy, the occurrence or absence of hæmorrhages, the general physical condition of the individual, possibly the history of a previous labor in the same woman with similar complications, all these should be taken into consideration in estimating the probable results of labor at term or in the latest months.

Reasoning from the large fatality incident to the care of most cases which have been recorded in former years, it would appear that an early induction of labor would result in the saving of maternal life, but, on the other hand, in recent years, the desire of obstetricians to save the children has been favored by the knowledge and experience gained in successful abdominal and vaginal surgery, so that we may not err in venturing to assert that in the future the obstetric literature may reverse the direful record with which, so to say, it has been stained in former years, in connection with the treatment of those cases of labor complicated with fibroid tumors, by a resort to the induction of labor after the completion of the seventh month or by laparotomy in some of its forms.

It only remains for me to add a few words concerning the relation of these tumors to the post-partum period.

It is a common experience that most of them rapidly become smaller after labor, sometimes, indeed, they seem to disappear entirely or nearly so, and this is true of the polypoid, intramural and subperitoneal forms. Occasionally the polypoid variety will slough, but it is then quite amenable to treatment.

The submucous variety, however, and too, the interstitial which during the hypertrophy incident to the period of pregnancy, has tended to become submucous,

commonly soon begin to soften more, to slough and become gangrenous, as did the one in the first case I have related. My error then, I believe, was in delay. Possibly an earlier interference with the view of removing the mass, by the curette or otherwise, would have made no difference in the final result, but upon general principles of uterine surgery, it appears to be eminently proper to attack such tumors at once, to remove as much of the sloughing material as we can, and to employ disinfecting agents with the utmost freedom.

Following this method in these cases of submucous tumors, we shall, at least as far as lies in our power, remove the source of systemic poisoning.

The danger from hæmorrhage with such treatment is overstated, for if the necrotic mass be removed quickly you will soon reach healthy tissue, which will not bleed very freely, just as is the case with similar treatment of malignant disease.

Another objection has been made, that by the exposure of such a large freshened surface to the lochial discharges, the chances of septicæmia would be largely multiplied, but I cannot appreciate the justice of this criticism, for surely the lochia cannot be so infectious as the sloughing and gangrenous material of the tumor, and too, the employment of the intrauterine disinfectants, if they serve any good purpose, certainly will tend to render the lochia innocuous.

Clinical Memorandum.

A CASE OF HÆMATOMA OF THE PANCREAS: DEATH IN THREE DAYS.

BY R. W. AMIDON, A.M., M.D., OF NEW YORK.

IN a recent number of the JOURNAL (October 28, 1886), Dr. F. W. Draper narrates five cases of extreme interest, in which pancreatic hæmorrhage coincided with inexplicable sudden death. It may interest those who read his paper to learn of a case in which death was *not* sudden, but in which pancreatic hæmorrhage was the only noteworthy lesion found. The case occurred in my practice several years ago.

A laboring man had been in perfect health until 10, A. M., June 23d. At that hour he was seized with nausea, vomiting, and slight diarrhœa. That evening, attacks of severe pain and cramps in the abdomen and stomach set in, which increased in frequency and force until the next evening, when I first saw him. He was then suffering severely. Countenance pale and haggard, body emaciated, and skin cold. Vomited matter was greenish; later, blackish (did not contain any blood-corpuscles). Frequent cramps run from abdomen into arms, and down legs, causing great muscular rigidity, and making patient cry out with pain. There was intense thirst. The urine was slightly albuminous. The treatment consisted in the free hypodermic use of morphia.

June 25th. The condition was unchanged; no movement from the bowels had occurred. A hypodermic injection of ether (3iss) raised the temperature from 97.6° to 99° F.

The patient died rather unexpectedly June 26th.

The pancreas was enlarged and hard. A hard, disk-shaped tumor, four centimeters in diameter, lay seemingly between the head of the pancreas and duodenum, and adherent to both. It presented, on section, a hard, blackish surface. On more minute examination, the tumor was found to encroach upon the substance of the head of the pancreas. The microscope proved the tumor unquestionably a hæmatoma.

New Instruments.

A NEW EAR-SPECULUM.

BY E. D. SPEAR, M.D.

AN ear-speculum, designed by the writer, was presented to several of the aural surgeons of Boston a year or more ago, was noticed by an aurist of another city in his "Treatise upon Diseases of the Ear," and has been of such service, that a description of it is here offered, that its usefulness may be further extended. Made more especially for an operative instrument, it serves equally well as a demonstrating speculum, fulfiling the object for which aural specula are intended; namely, the straightening of the auditory canal, the turning aside of hairs, bits of cerumen, or epidermal scales, and the removal of obstructing parts of the auricle, as the tragus.

As it is easily retained in position by the elasticity of the cartilaginous canal, and does not, therefore, require holding, the surgeon is enabled by its use to perform the usual operations without the aid of an assistant.

In reality, the instrument consists simply of those portions of an ordinary speculum actually in use during an examination of an ear. It is a short, flattened funnel, with a triangular flange projecting from, and forming one of its sides.

It need only be stated, in directions for its use, that this flange should be placed anteriorly, where it will be found pushing aside the tragus to allow light to enter the canal.

It is manufactured by Tiemann & Co., of New York, and may be obtained of them, or through Messrs. Goldthwaite & Co., in Boston.

ROBERT B. DIXON, M.D., SECRETARY.

NOVEMBER 17, 1886, DR. JAMES R. CHADWICK in the chair.

DR. W. E. BOARDMAN read a paper entitled

TWO CASES OF LABOR COMPLICATED WITH FIBROID TUMORS, WITH REMARKS.

DR. DRIVER, in opening the debate, mentioned a case of pregnancy in a woman about thirty-eight years old, complicated with a fibroid, apparently interstitial, filling the posterior *cul-de-sac*, the size of a small child's head, which he had sent to Dr. William L. Richardson, at the Boston Lying-in Hospital, for his opinion, Dr. Driver, seeing no way but to induce

premature labor. The woman had been delivered in England of five living children. The sixth labor was at term, and accomplished by craniotomy in presence of the tumor then not discovered, Dr. James Braithwaite, of Leeds, accoucheur; seventh pregnancy was terminated at the third month, premature labor being induced by Dr. J. Braithwaite; eighth pregnancy terminated at fifth month, premature labor being induced by Dr. J. Braithwaite; ninth pregnancy terminated at about seven and a half months, premature labor being induced by Dr. William L. Richardson at the Boston Lying-in Hospital. The woman went through four labors safely in presence of a fibroid tumor. Dr. Driver examined the woman November 19, 1886. Her health was good, but she could not work as hard as formerly. The os uteri was well forward, and up behind the pubic arch. The posterior *cul-de-sac* was filled by a large, slightly mobile fibroid the size of a child's head, apparently interstitial. No hæmorrhages.

Dr. Chadwick said that he had reported ten cases of pregnancy and labor complicated with fibroid tumors, of which eight occurred in his own practice, at the annual meeting of the Massachusetts Medical Society in 1885. He had found several signs of great aid in diagnosticating this complication, to which little or no reference was made in the text-books. First, presence of an area of flat percussions beyond the limits of the tumor or tumors previously known to be located in the uterus, the enlarging womb being so soft as often not to be felt beside the hard tissues of the tumor. Deep pressure in this region would, in the later months, reveal the fœtal parts. Second, the unduly rapid growth of a fibroid, especially if coincident with the arrest of menstruation. Third, blueish coloration of the vaginal entrance, which, though not always present, when manifest, is an indubitable sign of pregnancy. It has been asserted that this change of color may be produced by fibroids alone; this is an error, as he had established by a special study of the subject for the past ten years.

With regard to abortions, it has been shown by extensive compilations that they are no more frequent in this class of cases than in uncomplicated pregnancies.

With regard to the precise location of the fibroid, whether sub-peritoneal, interstitial or submucous, he had never been able to arrive at any conclusion when the case was first seen after the supervention of pregnancy, except in one where the fibroid presented at the os. The only practical division was into intra-pubic and abdominal growths. In the former group, the tumor obstructed the delivery, and efforts should be made to lift the tumor from out the pelvis, with the patient etherized, before labor set in. If this manœuvre was unsuccessful, premature labor should be induced. In the latter group of cases, delivery would be as easy as usual, except that there might be inertia of the uterus.

Dr. Farlow mentioned that in the only case he had had, the fibroid was at the fundus and subserous. The labor and convalescence were normal, except that the labor was much prolonged. In a case seen in early pregnancy, with the patient etherized and in the knee-chest position, he had succeeded in pushing an impacted fibroid out of the pelvis. After this there was no trouble. He thought that the diagnosis was often difficult, as the fibroid sometimes becomes quite soft during pregnancy. Contractions of part of the uterus, localized contractions of the abdominal muscles and the hard, small parts of the child are often very misleading.

Dr. Call said, in reference to her two cases of labor complicated by fibroids reported by Dr. Chadwick, that one of the patients had since been delivered again. At the first labor the tumor was half as large as the fœtal head, with a broad base, but at the second delivery it was not larger than a goose egg, and was distinctly pediculated. There was severe hæmorrhage after the first delivery from imperfect contraction of the portion of the uterus occupied by the tumor, but the second labor was normal in every respect.

Dr. Boardman, in closing the discussion, remarked that the three points in diagnosis mentioned by the Chairman are familiar. Some of them are subject to doubt, especially the vaginal discoloration of pregnancy; may find it from fibroid without pregnancy. It is difficult to diagnosticate the different varieties of fibroids, but the suggestions in the paper were for those cases in which the diagnosis is made. The submucous variety is the most difficult to make out, and he determines its presence by eliminating the other varieties, in cases where an unusual abdominal enlargement occurs with pregnancy, which manifestly is not due to fluid, or to the presence of more than one child.

OVARIAN TUMORS.

Dr. E. W. Cushing, in response to the request of the Secretary that members bring pathological specimens, presented four ovarian tumors, removed by Dr. H. O. Marcy, with his assistance, during the last two months at their private hospital. Also from the same source, a quantity of glandular tissue removed from the uterus by curetting, and sufficient to fill a four-ounce bottle. All the cases recovered without difficulty; in two of the four ovariotomies, both ovaries were removed.

Case I. A large, multilocular tumor, containing colloid material. Patient was sent to us by Dr. George Galvin, who had recognized its nature, although the patient stated that her former physician, a very distinguished practitioner, had declared that she was pregnant, and as she was a single woman, it had greatly troubled her and her family to have such an assertion made.

The walls of the cyst and of the daughter-cysts were very tough, so much so, that some of them could not be ruptured nor conveniently opened with the trocar, but must be incised. The very extraordinary luck of Tait, who had over a hundred consecutive cases which could be extracted through an average opening of two inches, as he says, is tempting surgeons to try to extract tumors through incisions manifestly too small; in this case, it was necessary to considerably enlarge the incision, in order to break up the smaller cysts, by introducing the hand into the tumor. A wound four inches long heals just as quickly as one of two inches, and gain in the strength of the scar in a small opening is too dearly bought if the operation is unduly prolonged, and all the risks increased, and the tissues of the abdominal wall damaged by trying to extract the semi-solid parts of the tumor through too small an opening.

Case II was a single, slow-growing cyst, with thick wall, and had no points of especial interest.

Case III. A dermoid cyst, with a thick wall; it is interesting because there is a plate of real bone at

the lower portion, with a long spine projecting into the cyst. There is also hair present. The diagnosis was confused by the fact that the Fallopian tube was spread out over the cyst right in the line of incision, and, being congested, it was a little difficult to be sure that the tumor was ovarian and cystic.

By the vagina, the harder, lower part of the cyst could be indistinctly felt, and when first examined, some two months before the operation, it seemed like a uterine fibroid. The patient was one of Dr. G. W. Jones's, of Cambridge, who kindly assisted at the operation.

CASE IV. A simple cyst, without adhesions, and contained twenty-eight pounds of fluid. The second ovary was removed, as it was undergoing cystic degeneration. Also the tubes, which were diseased.

These four specimens represent various forms of ovarian tumors, and two have been filled with water, and show the size, shape, and amount of fluctuation of the tumor.

It is of especial interest to note the length of the place of insertion of the pedicle, in one case four, and in the other over six inches. It is obvious that with the best of silk, and the tightest of knots, there is some danger that the ligature will slip. Of course, this danger is lessened by the customary method of transfixing the pedicle and tying each way, but even with this precaution, the ligature does sometimes slip, or from excessive tightness, strangulates a considerable mass at the end of the stump.

Dr. Marcy's method, as presented by him in a paper before the International Medical Congress, at London, 1881, and practised by him and others with the happiest results, avoids both these dangers. With a long needle in a handle, and having the eye near the point, armed with Kangaroo-tendon, he transfixes the pedicle near one edge, the tendon is unthreaded, and the other end passed through the eye, when the needle is withdrawn; thus some half-inch of the pedicle is enclosed in a loop, both threads crossing each other through one puncture. The needle, without unthreading, is then passed through again at an interval of half an inch or thereabouts, avoiding any visible vessels, is unthreaded then, armed with the free end, and withdrawn. Then another section is included, thus making a shoemaker's stitch, and so the whole long pedicle is sewn across, just as a saddler sews two pieces of leather together, except that the needle representing the awl carries the two ends of the thread alternately back and forth through one puncture, while the saddler uses waxed ends, which cross through the opening made by the awl.

Thus every vessel is tightly ligatured, and when the sewing comes to the further edge of the pedicle, the tendon is knotted, and may then be passed round the whole and knotted again. The peritoneum is then carefully stripped, as was demonstrated to be possible by the late Dr. Mines, of Buffalo, and dissected from the tumor all round, leaving a free border of half an inch.

With a small needle armed with catgut or fine tendon, the peritoneal surface is then gathered in with a "sero-serous" continuous suture. In this way, there is no need of any thermo-cautery. There is no risk of bleeding; the tendon not only remains long enough, but becomes organized as a part of the tissues of the stump.

There is no strangulated, charred, necrotic mass as a source of danger, and no fresh, open surface to absorb any secretions which may collect in the pelvis, and be more or less septic.

These advantages amply pay for the extra time and trouble of properly sewing up the pedicle, for the extra time required is very little, and the trouble is of no consequence.

The case of curetting of the masses of glands, an operation now performed by Dr. Marcy for the fourth time on the same patient, with more and more rapid recurrence after each operation, will be reported in full at a later time. Notwithstanding the amount removed, and the thinness of the uterine wall left, she had an uninterrupted convalescence.

SUFFOLK DISTRICT MEDICAL SOCIETY.
SURGICAL SECTION.

S. J. MIXTER, M.D., SECRETARY.

APRIL 7th, 1886, DR. G. W. GAY presiding.

DR. D. W. CHEEVER reported two cases of

EXOSTOSIS OF FACIAL BONES.

These cases are reported on account of their comparative rarity, only seven cases being mentioned in Heath.

The first patient was a young man of nineteen years. When twelve years old a hard lump was noticed below each eye, gradually increasing in size, until at the time of operation the eyes were very prominent and pushed up, the nose was flattened and the nostrils occluded, the patient presenting the characteristic "frog-face" appearance. He was very desirous of being operated upon.

The deformity existing on both sides of the face, it was not considered best to remove both superior maxillæ. The chief difficulty in the operation seemed to be in preserving the bridge of the nose.

Curved incisions were made over the tumors, and the overlaying parts having been pushed back with the periosteum, the tumors were chiseled off, on one side leaving orbit and nose untouched, and on the other side making a small opening into the nose, the tumor on that side being attached to the nasal bone and the mass harder and having a broader base than that on the other side.

The patient made a good recovery, and when last seen his appearance had much improved, as well as the sense of sight and of smell.

The bony masses removed were fairly hard, but not like the ivory exostoses spoken of by Heath. They were also unlike the bony exostoses with pedicles that generally start from some mucus cavity like the frontal sinus.

The second patient was a young woman twenty years old. The temporal fossa was filled with a hard, even mass under the muscle. A curved incision to the temporal ridge having been made and the flaps turned down, the mass was chiseled away as far as possible. This tumor was harder than those in the other case, and it was difficult to tell when a sufficient amount had been removed, as no line of demarkation existed between tumor and skull.

Now, two years after the operation, there has been no return of the tumor externally, but the patient has defective vision and hearing, and epilepsy. The latter has improved somewhat under bromide, but the prog-

nosis is unfavorable, as the tumor is probably growing inside the skull.

DR. FITZ referred to a possible result of the operation for the removal of orbital exostoses as illustrated by a specimen in the Warren Museum. The patient was operated on by Dr. R. M. Hodges. The exostosis was ivory-like, and projected from the forehead. It was subsequently found to protrude into the cranial cavity.

Although the condition of the patient was satisfactory for a fortnight after the operation, death occurred a few weeks later from abscess of the brain.

In reply to Dr. Gay, the reader said that in the first case there was an enlargement on one lower alveolar process, and the right antrum was also somewhat enlarged. The palate bones met at an acute angle above, and the upper incisors overlapped. These latter deformities were probably congenital.

DR. GAY spoke of a case operated upon by Dr. Charles D. Homans, at the City Hospital, for bony tumor below the eye. The deformity was entirely removed, but the subsequent history of the patient was unknown.

DR. CHEEVER said that he considered the method of operation in these cases to be exceedingly rude, and that the dental or surgical engine with its saws and burrs would do the work much more rapidly and safely.

DR. GEORGE G. HAYWARD reported a case of

COMPOUND COMMINUTED FRACTURE OF THE LEG,

exhibiting the patient.

Dr. Hayward spoke as follows: The case seems of interest not so much from its rarity, as its extreme severity and subsequent good recovery under most unfavorable circumstances. Patient, a sailor, was injured in service during a gale, being caught by the main boom penant and main sheet.

He sustained the following injuries, namely: a compound comminuted fracture of the left leg, with a ragged flesh wound over the seat of fracture to the inner aspect of the leg, four and one-half inches in length, also a deep lacerated wound of the left thigh, six inches long, about the middle and transverse in direction.

He was sent ashore at a small town on the coast of Maine, and seen first by the local physician, and after many hours by quite a prominent surgeon twenty-five miles distant.

Examination of the injuries gave only a faint hope of saving the limb, and this was rendered the less from the fact that the surgeon had no confidence in the local physician with whom he was obliged to leave the case.

The wounds were carefully dressed, and some few fragments of bone removed, antiseptic precautions observed, sutures and splints applied. The after treatment was left with the local physician.

Four days after this, during sleep, the patient turned in such a way as to cause intense pain. He could feel the bones rubbing against each other, and was conscious that the limb was out of place. In this condition he was allowed to remain for six days.

On the 4th of July last, ten days after the injury, I was called upon by one of the summer visitors to take charge of this case.

The following will serve to show the condition of things as found at that time, and also give a brief history of the case.

There was considerable amount of shortening (two and one-half inches); no attempt at union. The bones could be seen from the external wound, and felt gliding past one another, being freely movable. The foot was cold, and no pulsation could be detected.

The wounds were extremely foul; the upper one was almost gangrenous, and a large mass of material had to be trimmed away with the scissors before dressing it. The patient objecting to ether, morphia was given subcutaneously before attempting to disturb the fracture. The reduction was easy, and the limb placed in position in an apparatus adapted to the case, and so arranged that the wounds could be dressed without disturbing the fracture, and rendered fixed by heavy sandbags. Attention was also paid to antiseptic precautions and drainage.

After a few days, the pulsation in the foot became evident, and the general condition of the patient began to improve under tonics and a more liberal diet. At the end of nine weeks there was a firm union, but small, granulating surfaces remained, the limb remaining in the apparatus until everything was perfectly solid.

About the middle of September, a plaster-bandage was substituted, and the patient was allowed to go about on crutches a little. After this, the bandage was split and laced.

During the winter two small fragments of bone came away. He now walks with a slightly thicker sole on the injured side. By measurement, the shortening is scarcely perceptible. He is free from pain, is perfectly well, and able to be at work.

DR. H. W. CUSHING exhibited a patient showing the result of an excision of the elbow, performed four years and a half previously.

Dr. Cushing spoke as follows: The patient I have here to-night, a German, aged sixty, and an artist by profession, was admitted for treatment at the Boston City Hospital on November 15, 1881, for chronic arthritis of the right elbow. His previous history was good. Also no predisposition to disease from hereditary influence was recorded. The only discoverable cause for his condition was that in 1878, three years previous, he had received a contusion of the right elbow from falling on a slippery pavement. No especial trouble was reported until 1879, when slight limitation of arc of extensor appeared. Slight swelling followed the periarticular induration. Gradually-increasing impairment of motion and power of the joint, accompanied by pain. Afterwards, formation of sinuses and prolonged suppuration.

Examination at the time of operation (December 2, 1881), showed such extensive destruction of the articular structures, that an amputation was seriously considered. The patient's general condition also rendered it uncertain whether he could survive the prolonged aftertreatment of an excision.

However, the importance to the patient of preserving the use of his right hand was so great, he being practically dependent on its integrity for its livelihood, that it was decided to make an attempt to retain it. The joint was excised by Dr. W. H. Thorndike through a post-longitudinal incision in the usual way. The humerus was divided above the condyles; the ulnar and radius in a horizontal plane at the level of the radial neck.

The patient remained in the hospital till May 2, 1882, and was then transferred to the Out-patient Depart-

ment. His general condition at this time was good. There was a slight suppuration from several unclosed sinuses about the elbow, at the ends of which a probe grated over an uncovered bony surface. There was limited motion of the elbow in all directions. Motion of the fingers slight, but gradually returning.

In June, 1882, seven months after operation, fixed apparatus was omitted, and from this time until June, 1883, thirteen months after operation, when the patient was discharged well, the treatment consisted in cleanliness, by irrigation and absorbent dressings, usually gauze or oakum, alternating with stimulating lotions. Prolonged, systematic, passive motion and massage seem to have aided much in restoring the mobility of the hand and fingers.

From January, 1883, till now, the power of the elbow, and mobility of the fingers have steadily increased, so that now the patient is able to use his hand at his work as well as formerly. The elbow has gradually changed from a mere "flail" to a joint of considerable power and utility. Diminished power of extension of the wrist, and diminished power of grasping objects with the fingers, are the only noticeable abnormal conditions of this part of the extremity.

The patient can carry articles of considerable weight, can drive nails with a hammer, raise the hand to his mouth, and performs his work as an artist so as to support himself and family — a result which, when the age of the patient and the condition of the articulation at the time of operation, are considered, is exceedingly satisfactory both to patient and surgeon.

DR. CUSHING also reported a case of

PHTHISIS, TUBERCULOUS SYNOVITIS, AND CARIES OF THE WRIST: EXCISION, WITH RECOVERY FROM LOCAL CONDITION.

The patient first had pleuritis about two years ago. This was followed by trouble in the wrist-joint, which gradually increased until the time of the operation, September 8, 1885, when there was marked tuberculous disease of the left apex, and advanced caries of the left wrist. This was excised by a median dorsal incision (Langenbeck's operation). In eight months and three days from the operation, the wrist was completely healed. The patient's pulmonary trouble remains about the same. He has occasionally slight cough and night-sweats, but the general condition is steadily improving, and the power and usefulness of the hand is also increasing, so that it promises to become an exceedingly useful member.

THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, December 2, 1886.

DR. J. BLAKE WHITE presented a

PHTHISICAL LUNG INJECTED WITH CARBOLIZED IODINE.

He said that the results which he had met with during the past year from injecting diseased lungs had greatly excited his enthusiasm. Theoretically, intrapulmonary medication seemed to be a very rational method of treatment, and practically it was found to be of much efficacy. Having referred to the success met with by Drs. Pepper, Robinson, and others, he mentioned a case of his own in which recovery took place, and the course of which was watched with interest by three professional friends. The preparation which he prepared for injections was a mixture of carbolic acid and tincture of iodine, to which was added a small amount of morphia and atropia. In the cases in which he had employed it all the symptoms had been relieved, the cough being controlled, expectoration diminished, sleep improved, and night-sweats checked. The specimen presented was the left lung of a patient in whose case, although hopeless as regards cure at the time the first injection was made, the effect of the treatment was very marked and gratifying.

The patient was a milk-man, a native of Ireland, and forty-six years of age, and Dr. White gave a somewhat detailed history of the case. When first seen by him at Charity Hospital last summer, he was in the third stage of phthisis, with a large cavity in the upper part of the left lung, which was in a state of active suppuration. There was profuse expectoration, exhausting night-sweats, and all the ordinary symptoms of advanced pulmonary tuberculosis. On the 19th of July, the first injection of ten minims of carbolized iodine was made in the first intercostal space. It was followed by no reaction, and there was immediate and marked improvement in the patient's condition. The following week a second injection of the same character and quantity was given, and this also, without any reaction whatever, was followed by marked improvement in all the symptoms. The man felt so much better, indeed, that he was enabled to make an amount of physical exertion that, before the treatment, would have been impossible. On the 30th of August, a third injection was made, this time twenty-five minims of the carbolized iodine being employed. It was attended by a brief paroxysm of coughing, but no bad results followed, and marked improvement was subsequently noted in the symptoms as before. Dr. White's term of service at the hospital now expired, and no more injections were made.

The patient died October 19th, and at the autopsy the left lung was found bound down everywhere by the most extensive pluritic adhesions. The pericardium was also involved by adhesions to a very marked extent. Much of the tissue of the diseased lung presented a cirrhotic appearance, and in the vicinity of the cavity in the apex a considerable space was found to be tinged by the injections. The upper portions, where the injections had been made, presented a marked contrast to the lower portions, where the tissues were in a state of advanced disintegration. During life, also, the auscultatory signs had indicated a dry condition of the upper parts very different from that met with in the lower. Very little pus was found in the cavity.

DR. WILLIAM P. NORTHRUP read a paper on

LARYNGEAL DIPHTHERIA; INTUBATION AND PATHOLOGICAL ANATOMY.

He commenced by alluding to the conflict of Bouchat in behalf of intubation of the larynx with Trousseau and the mass of the profession in Paris in 1858, which ended in the official declaration by the Academy of Medicine that this procedure was impracticable. It was true, he said, that Bouchat's seven cases all terminated unfavorably, but this fact at least was proven, that the larynx will bear a tube. It was also shown that the stenosis had been relieved in Bouchat's cases. Having described Bouchat's tube, he said that nothing more was heard of the method for nearly thirty years,

when it was revived by a Fellow of the New York Academy of Medicine, Dr. Joseph O'Dwyer, in a manner which at once compelled the attention of the entire profession.

Dr. Northrup then proceeded to give the statistics of all the cases of death from laryngeal diphtheria which had occurred among the children connected with the New York Foundling Asylum during the past five years. The number of children belonging to the institution is about 1,800 per annum, of which 1,100 are cared for by paid nurses in their own homes, and the rest accommodated in the asylum buildings. There were 87 deaths in all from this cause, of which 50 were in females and 37 in males. The greatest mortality was found to be between the ages of three and four years. In 56 the membranes began to form in the larynx before or simultaneously with the exudation in the pharynx. In two cases croup was the first symptom noticed, and death occurred within twenty hours. In 54 cases there was pneumonia, and broncho-pneumonia was very frequently met with. 27 children died from extension of the membranes into the bronchi, and in 29 the pneumonia was sufficiently severe to cause death alone. The highest temperature met with was, in 19, 104°, in 15, 105°, in three, 106°, in two, 103°, and in one, 107°. Having given statistics of the extent of the membranous exudation, he said that in all but three of the 87 cases the membranes were very extensive. Interstitial emphysema occurred in eight cases. There were 51 cases of primary diphtheria, and 31 in which the disease was nearly or remotely related to scarlatina or measles.

Dr. Northrup exhibited a set of O'Dwyer's instruments for intubation, and explained the method of introducing and extracting the tube into and from the larynx. It was important, he said, that the child, wrapped in a blanket, should be held upright in the arms of the nurse, who by grasping the elbows could secure a firm position without interfering with respiration. The gag was to be inserted in the left angle of the mouth, well back between the teeth, and opened widely. An assistant held the head, thrown somewhat back, while the operator used his left index finger to hook up the epiglottis and direct the tube into the larynx. It was better to make several short attempts to introduce the tube than one prolonged effort, on account of the interference with respiration thus caused. The extraction of the tube was more difficult than its introduction, and Dr. Northrup, at the suggestion of Dr. O'Dwyer, recommended that physicians should practice both introduction and extraction upon the cadaver.

Those beginning to practice intubation, he estimated, were apt to use too small a tube, with the result that it was coughed up. Care should be taken, therefore, always to use the size of tube suitable for the age of the child, as indicated by the scale accompanying each set of instruments. There was, however, no danger of the tube slipping down into the trachea, as some seemed to fear; since the head of the tube could not fail to be caught by the cricoid cartilage, which was situated at the narrowest point of the passage. There was also no danger of ulceration of the vocal cords being caused by the tube.

If the condition of the child was favorable for forty-eight hours after the insertion of the tube, the prognosis would be good; but it was entirely unsafe to give a favorable prognosis at any period before the expiration of the forty-eight hours. Not infrequently the greatest possible relief was temporarily secured by intubation in cases which afterwards terminated fatally by the extension of the membrane downwards or by the occurrence of pneumonia. Dr. Northrup also spoke a word of caution in regard to withdrawing the tube too soon. Whether it would be advisable to re-introduce the latter in any case would depend on the condition indicated by an examination of the chest. If on auscultation the vesicular murmur was normal, there was no cause for uneasiness; but if it was found that the air could not get well into the lungs, especially the posterior portions, it was time to re-introduce the tube. The condition of the pulse also served as a valuable guide to the experienced. In many cases the tube could be removed with safety in five or six days.

After referring to the kinds of food which are most useful and most easily taken after intubation, he referred to the cases reported by Dr. Jennings, of Detroit. They were four in number, and as all proved fatal, Dr. Jennings recommended tracheotomy in preference. It was a fact, however, that all his cases were of a very unfavorable character. Still, he recommended intubation in children under fifteen months old and in hopeless cases; believing that it was a supplement to, though not a substitute for tracheotomy.

Having mentioned that O'Dwyer's tubes were of great service in stenosis of the larynx in adults, and especially when the condition was due to syphilis, Dr. Northrup gave some general conclusions in regard to intubation, among which were the following: It relieves dyspnœa due to laryngeal stenosis, and is open to few objections. It is comparatively simple, and is also free from danger. No anæsthetic is required, nor is there need of a trained assistant. There is no fresh wound to serve as a new focus for infection. If intubation proves inefficacious, tracheotomy can still be performed. Intubation, however, he said, had one conspicuous fault, namely, that it embarrasses and sometimes interferes with deglutition. There was also one danger connected with it. The tube might possibly push some of the tenacious membrane down before it, and thus cause a blocking up of the trachea below.

Did it meet the requirements? The statistics showed that it undoubtedly did. Waxham had had ninety-six cases and O'Dwyer forty-eight, and in the one hundred and sixty-five cases which had thus far been reported, no less than twenty-eight and one-half per cent. had been saved. It was to be remembered, too, that the method was still new. Valuable experience had been gained, and it could scarcely be doubted that in the future the results would be even more favorable. The statistics of tracheotomy showed no such satisfactory result as this, and he believed that if all the fatal cases of the operation were reported, the percentage of mortality would be considerably larger than it now appears.

In the discussion which followed, Dr. Francis Huber said that he had performed intubation eleven times. The special conditions for which he had resorted to it were aphonia, stridulous expiration, and extreme recession of the chest-walls, above and below the sternum. He gave a brief sketch of each of his cases, and then stated that out of the eleven, there had been four recoveries, while one child was still wearing

the tube. Five had died, and one other, in which he had just practised intubation, would probably also prove fatal. These results were much better than he had obtained with tracheotomy. He had performed this twelve times, but had saved only two out of the twelve children. He stated also that in all his cases of intubation, the method was resorted to very late. In conclusion, he exhibited a modification of the O'Dwyer gag, devised by his friend, Dr. Denhard, who had also had eleven cases of intubation. Five of them were successful, and all of the eleven, like his own, were late cases.

DR. A. S. HUNTER related two cases, both severe, in consultation, in which he had practised intubation. The first was that of a child six years or age, who had been suffering from membranous croup for two days. The stenosis was extreme, and pulmonary œdema was coming on. He introduced the tube with little difficulty, and the relief was immediate and very marked. After forty-eight hours, however, he saw the patient again, and found the respiration very rapid. It had great difficulty in swallowing, and he found that by giving it a large quantity of nourishment at a time, it did better than if the attempt was made to give it by the teaspoonful. The pulmonary trouble was now so great that it was evident that the child could live but a few hours longer. He therefore removed the tube, and found that it breathed well without it. Death occurred about seven hours afterward.

The second case was in a child two and a half years old, with diphtheria, who had a temperature of 103.5°. There was marked stenosis of the larynx, and it was almost completely asphyxiated. The relief afforded by intubation was, as in the other case, prompt and satisfactory. The next day, however, the child coughed the tube up, and it was re-introduced by the attending physician, but death ensued in five or six hours later. Dr. Hunter stated that he had practised intubation five or six times on the cadaver before he attempted it on the living subject.

DR. E. L. PARTRIDGE said that Dr. Northrup had mentioned that the only danger from intubation was the possible detachment of portions of membrane, which might act as a diaphragm in the trachea below the tube. The same objection held true, however, in regard to tracheotomy, and he referred to a case of this operation, in which fatal obstruction occurred in the manner described.

DR. A. G. CAILLE said that he had had one case of intubation, but the procedure was resorted to at so late a period, that he thought it should not go on record. He believed that the introduction of the tube would be rendered easier if the special points of the anatomy of the parts were carefully borne in mind.

Recent Literature.

On the Healing of Arteries after Ligature in Man and Animals. By J. COLLINS WARREN, M.D. New York: Wm. Wood & Co. 1886.

In this book, the author has given the results of his own investigations on a most interesting subject. A long line of experiments, carefully conducted and closely observed, are the basis for his deductions. These differ in many essential points from those of other investigators, which are brought together in a historical abstract in the introductory chapter. The main points brought out are the length of time required to fully complete the healing, from three to six months being necessary. Then the part played by the new tissue formed about the vessel, and which acts as a callus, both without and within, to support it until entirely occluded. Further, the participation of the muscular coat in the process, which has been disregarded by other writers. The fact of the presence of a thrombus in all cases is strongly insisted upon, although of much less size when antiseptic precautions were used, its period of greatest usefulness being at the time when the walls of the vessel are retracting, preventing, on the one hand, the escape of blood; and, on the other, serving as a culture medium for the new cells.

The manner, too, in which the vessel opens again, and the new tissue penetrates to form the lasting cicatrix, is very well illustrated and made prominent. The idea that the endothelial cells take any prominent part in the process is refuted by his experiments, there having only been observed an occasional thickening of the inner coat, which might aid in fixing the thrombus, but nothing more.

Only an extended extract would do justice to his work, which he has carefully summarized at the end, and which should be seen in the original. An extended bibliography and a capital index complete the book. The illustrations, which are entirely from his own specimens, are very numerous, and show clearly the points intended.

We look upon this as a distinct contribution to the science of medicine, on a side which the calls of everyday practice leave untouched for so many. It only remains to add that the publishers have in their liberality made the volume fittingly attractive.

Massage as a Mode of Treatment. By WILLIAM MURRELL, M.D., F.R.C.P., Lecturer on Pharmacology and Therapeutics at the Westminster Hospital; Examiner in Materia Medica in the University of Edinburgh, and to the Royal College of Physicians of London. Philadelphia: P. Blakiston, Son & Co. 1886. pp. vi. 78.

The reason given by the author for the preparation of this work is that he has received many letters from physicians in England, asking for information about the therapeutical value of massage, in consequence of his having delivered a lecture on the subject in December, 1885. From this it must appear that interest in massage in England is just ten years behind that of Germany, for in 1875 it was an everyday question amongst many physicians in Germany as to what massage meant. Long before that time massage was well known in America. After a short introductory chapter comes a brief outline of the history of massage, which, with much of the rest of the book many of our readers will recognize as having been already more fully published in the United States, in a recent work on massage.

The experiments of Von Mesengeil, showing the increased power of absorption of foreign substances from the joints of rabbits under the stimulus of massage, Dr. Murrell thinks, has placed the whole subject on a firm basis. In 1878, it was thought by some that Weir Mitchell's thermometrical observations placed massage on an exact scientific basis. But more

enlarged views of the subject must prevail. In the chapter on the method of performing massage, appropriate excuse for brevity and omissions is made in the statement of the author that it is almost as impossible to teach the art of massage by written or verbal description as it would be to make a piano-forte player without recourse to the instrument. It is a puzzle to us why he and many others state that in doing the deep manipulation the hands must move simultaneously and in opposite directions. This produces a sensation of tearing of the skin; whereas when moved *alternately* in the same or opposite directions the effect is soothing. And yet Dr. Murrell wisely insists on massage being skilfully done by people of education and refinement, and instances the fact that Dr. Mezgr and Professor Von Mesengeil are their own operators.

He asked a medical friend if he used massage in his practice. The reply was "Oh yes, a good deal, my butler does it." After that he should not be surprised to hear that the electrical treatment was conducted by the footman and that the kitchen maid undertook the obstetrical cases.

The author advocates short séances of eight or ten minutes, repeated three or four times a day, and whenever it is possible the patient should go to the house of the operator so that the latter may not be fatigued by travel.

In the chapter on the physiological action of massage the principal item with which we were not already familiar is that of Gapadze's experiments on four healthy men, showing that the temperature in the axilla fell for about half an hour after each massage, but not more than half a degree. After this it rose steadily, and an hour later it was generally a degree higher than at the beginning of the massage. Here he also speaks of the efficacy of massage in hastening the union of fractures as a fact now well established, but does not tell us when or how it should be employed, whether early, to hasten absorption of an unusually large effusion, or late, to stimulate delayed union, or whether all fractures would unite more speedily if massage could be applied without disturbing the fragments.

In place of the somewhat sentimental description of the symptoms of infantile paralysis it would have been better if the author had occupied the space by more clearly defining the indications that would lead us to hope for improvement from massage in such cases. His theory of its action (given in another chapter and somewhat out of place) is that the nutrition of the parts is maintained until new cells in the spinal cord take on the functions of those which have been destroyed. He has had many of these cases under observation "and in every instance in which the treatment was carried out actively and systematically the best possible results were obtained." He regards electricity as a useful adjunct. In recent cases the prognosis is given as good, but in old cases a cautious opinion is best. To our way of thinking, the extent and severity of the central disturbance has more to do with the prognosis than the length of time it has existed. Dr. Murrell says nothing about remedial movements or medical gymnastics, which are of even greater importance than either massage or electricity where a little healthy muscular tissue and slight power of motion still remain. He also states that massage is of great benefit in locomotor ataxia, pseudo-hypertrophic paralysis, facial paralysis, wasting palsy, and allied conditions. He finds massage of great value to reduce corpulency, especially in ladies about the age of thirty-five who have led a sedentary life. But we are not told what sort of adipose tissue is susceptible of decrease, whether hard or soft. We suspect it is only the latter.

Inasmuch, as the author respects the limited space he has allowed himself, we cannot understand why he should have wasted some of it by sensational quotations of faith cures, and the cure of a startling case about which it was not very clear what the matter was. For vague uneasy pains sometimes called rheumatic, neuralgic or growing pains, Dr. Murrell finds that massage affords prompt relief. In *neurasthenia spinalis* he has found massage to be of the greatest use, and he knows of no class of cases in which massage does so much good as in spinal irritation. A careful reader, however, will observe that in quoting some causes of neurasthenia from a recent American work on massage, the quotation is too limited and does not, for this reason, do justice to the original.

For some years there has been a prevalent opinion amongst physicians in London that massage should not be used in cases suffering from heart disease. We have employed massage in almost every form of disease of the heart with, at least, temporary relief even up to the day of the patient's death. It is a satisfaction to have this experience in part confirmed by Dr. Murrell who narrates a case with a loud systolic murmur, a weak and irritable heart that had massage four times weekly for six weeks and improved from the first, becoming better than for many months.

There is also a chapter on joint affections in which the author tells us that most of the cases that he saw treated by Von Mesengeil on the Continent, would have been considered incurable in England. Mention is here made of that curious old book which describes the system and results of friction as used by Professor Grosvenor, of Oxford, a century ago, and regret is expressed that there is no copy of it in any of the medical libraries of London. Dr. Murrell recommends it as well worth reading. But how can it be extensively read if it is so scarce? We are the fortunate possessors of a copy, and all there is of value in it will be found in Graham, on Massage.

The remaining points worthy of notice are that the author has found massage of undoubted value to prepare the system for the assimilation of iron in anæmia, to improve the strength and nutrition in cases of debility after the active symptoms of syphilis have subsided, and to maintain the temperature in cases of acute chloral poisoning.

The chief value of the work is a vigorous confirmation of what has been previously said on the subject of massage, and this coming from a man of such wide reputation will help to raise it in the esteem of the profession. The book is easy and pleasant reading, and is to be heartily commended to those who have not time to read more fully on the subject. But for those who do, it would have been well if the author had referred others more directly to his own sources of information. The index is too copious and has references without meaning, as will be seen by looking for information about lateral curvature. Nothing is said about the effects of massage on this.

Dr. Benjamin Lee's "Tracts on Massage," are much more carefully prepared and will prove more satisfactory to those who desire accurate information.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, DECEMBER 23, 1886.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES, UPHAM & COMPANY,
283 WASHINGTON STREET, BOSTON, MASS.

THE TREATMENT OF FRACTURES OF THE LOWER END OF THE HUMERUS.

FRACTURES about the elbow-joint will probably always be a source of anxiety to the surgeon. Difficulty of diagnosis, difficulty of retaining fragments in place, the frequency with which the joint is involved, make the results often fall short of perfection and bring deformity to the patient, and chagrin to the attendant surgeon. Fractures into any joint are specially liable to impair the functions of that joint; fractures into the elbow-joint are no exceptions to the rule, and an unfortunate result does not render it necessary to incriminate the method of treatment. A certain number of cases must inevitably be followed by impaired motion.

To those who were fortunate enough to listen to or even read the spirited lecture of Prof. Henry J. Bigelow on "Fractures of the Elbow-joint," such an article as the one we publish to-day seems like heresy. Fractures about the elbow are usually treated in Boston in accordance with the teachings of that lecture which are summed up in the following rule:

"Ascertain if the olecranon is broken. . . . In all other injuries of the elbow-joint whether you are able to make an exact diagnosis or are wholly unable to do so on account of the swelling, *treat them as though the forearm had been dislocated backwards, and secure the arm at about right angles to an inside angular splint.*"

This splint, which might be described as an anterior right-angled splint quite as justly as an inside angular splint — the *inside* referring to the angle and not to the side of the arm — should be solid, or at least firm, and not with a loose hinge-joint at the angle that allows play in all directions and forbids any idea of fixation.

"The character of the injury is determined as far as may be without unnecessary harm from manipulation of the parts, and the elbow being placed at right angles, the wrist is drawn forward while the humerus is pushed backward at the elbow, precisely as if a backward dislocation was being reduced. In this position it is forcibly maintained while the fragments are adjusted as far as may be and an internal angular splint padded by a folded towel is applied by an assistant."

To this it might perhaps be added that a sling needs to be carefully adjusted so as to keep the forearm so raised as to relieve the splint and bandages of the weight and leverage of the forearm and hand. Careful manipulation of the injured elbow, and the addition of any pads and additional splints that each case may call for, may add greatly to the accuracy of adjustment, and assist in gaining results that will leave little to be desired; then a careful supervision to see that the position is maintained, and bandages do not slip, can never be omitted.

The published lecture [1] of the eminent professor to which we have referred, contains also a condemnation of the practice of passive motion as applied to the elbow-joint, which was characterized as productive of more harm than good.

In order to obtain the best possible result in any fracture, one must direct all his efforts to place the broken bones in their normal position and maintain them in such position until union has taken place, due regard being had to the integrity of the soft parts meanwhile. Pumping the joint in the immediate vicinity of the break is certain to interfere with the careful approximation of the fragments, either by direct action or by provoking contraction of some of the periarticular muscles, and is even more likely to impair the result than to improve it. Absolute immobility offers the surest means of obtaining early union with a minimum of callus, and the least inflammatory complication.

It seems worth while to quote in full the statement of Dr. Ingalls to which reference has been made in the article of Dr. J. S. Bigelow. Under the heading "Hospital Notes" occurs a short article "On the Treatment of Fractures of the Upper Extremities in Boston Hospitals. (Specially reported for the *Medical News*,") but the name of the reporter is not given. In that article occurs the following:

"Simple fractures of the lower third of the humerus are put up in an internal angular splint; and this splint is also used for all fractures about the elbow, whether above, through or below the joint, except those of the olecranon.

"Dr. Ingalls, of the Boston City Hospital, is of the opinion that in many cases of fracture of the humerus near the elbow-joint, the best treatment is to make traction with the arm extended instead of being flexed around an internal angular splint; and he intends to treat these fractures in the above manner, and to pay particular attention to the use of passive motion as early as possible."

Certain exceptional cases are then mentioned in which the patients are confined to bed and extension applied. These latter cases are certainly very rare and include few cases besides those of such extensive injury that splints are for a time out of the question,

[1] Boston Medical and Surgical Journal, May 7, 1868.

and these are often fractures in the shaft of the humerus, above the region of the joint.

In quoting authorities, Dr. J. S. Bigelow does not give a passage from Hamilton which tells most strongly in favor of the position he advocates, though expressing a different opinion as to the muscular action: "Although the flexed position must usually be regarded as the best in these fractures (fracture at the base of the condyles, complicated with fracture between the condyles, extending into the joint), for the reason that it most completely relaxes the biceps, brachialis anticus and the flexors of the forearm, and because if anchylosis ensues, the flexed position gives the most useful arm, yet, I think it might be proper to try what better can be accomplished by permanent extension with the forearm straightened upon the arm," etc.

No one can read for the first time the articles which Dr. Allis [2] has published upon the subject of fractures of the humerus without treating fractures in the vicinity of the elbow the better for it, but the straight position is not the inevitable and only refuge from the evils to which he draws attention. And one cannot fail to be struck by such a remark as that of George R. Fowler [3] in a discussion on a paper of Dr. Allis's; "The only case in which there was any considerable loss of movement of the joint was one which I saw in consultation, and advised its treatment in the nearly straight position."

But the final and conclusive argument is the greater utility of an arm anchylosed at a right angle than that of one immovably straight. Any one who has been enabled to watch an otherwise healthy boy with an arm fixed in a straight position, will be very careful how he exposes one of his own patients to the risk of such a misfortune. The straight position cannot overcome the dangers inherent in a fracture into the joint, and the surgeon who adopts that position would certainly abandon all its fancied advantages if an anchylosis should once unfortunately occur in such practice.

CEREBRAL LOCALIZATIONS.

At the meeting of the Imperial Royal Society of Physicians held in Vienna, November 19th, Exner made an address on cerebral localizations, in which he summed up the present status of physiological opinion on the subject, reviewing the published declarations of the principal authorities, and comparing them with his own views.

Taking for his point of departure the late discussion at the Assembly of German Physicians and Naturalists at Berlin — a discussion rendered memorable by the participation of leading physiologists who have made a special study of cerebral localizations — and after a rapid review of the views of Munk, Ferrier, Hitzig and Fritsch, Luciani and Sepilli, Charcot and Pitres, Exner remarked that, according to his own scheme, the centres of the different functions are not isolated, but inter-connected, each with each in the cerebrum.

Paneth has clearly shown that Hitzig's centres (which differ but little from Ferrier's) represent only the *maximum* of excitability of the sense or motor function therein localized. Hitzig has, moreover, adopted this statement, as harmonizing with the facts which he has witnessed. Charcot and Pitres, Luciani and Sepilli, oppose Exner's views, while admitting the inter-connections of the various centres. After this general survey, Exner takes up the consideration of the different centres.

As regards the motor area in the dog, Exner asks if this area be really circumscribed, or if it extends beyond the limits indicated by Munk. Munk presented to the Assembly of Naturalists a dog which he had rendered blind by removing the occipital lobes; but, as this animal could not descend a flight of stairs, Goltz affirmed that there must be a lesion of motility also, for a dog, simply deprived of its visual lobes, ought to be quite able to descend stairs. Munk, in commenting on this objection, affirms that a dog from which a part of the cerebrum has been removed must comport itself differently in its movements from a dog whose cerebrum is intact, meaning by this that the motor functions of the dog are impaired; hence the occipital lobe not only contains the visual centre, but the motor area extends also into this lobe. Goltz has declared that the results which he has obtained are not in contradiction with those of Exner and Hitzig. Fritsch, moreover, led by anatomical considerations, has pronounced against the exact limitation of localization, so that a majority of physiologists are agreed as to what concerns the motor sphere. Among the sensorial zones, the visual centre is the best known and the most important. According to Munk, the visual zone is very limited; Goltz protests against any such limitation, and Hitzig, Luciani, and Sepilli are in agreement with him. Exner and Paneth have determined lesions of the sigmoid gyrus in ten dogs. Nine of them had visual troubles, but it is possible that these were due rather to a "lesion of attention" than of true vision.

Is it possible to render mammals blind by extirpation of the occipital lobes or of the entire cerebral cortex? Frogs preserve their visual faculty intact after extirpation of the whole of the cerebral cortex, and it is the same with birds. Nevertheless, Munk pretends that pigeons become blind after extirpation of the entire cortex. Gudden has removed, in hares, the greater part of the hemispheres, and these animals do not become blind.

Munk has demonstrated that a dog may be rendered blind by extirpation of the occipital lobes. Goltz presented to the Assembly of Naturalists the cerebra of dogs, which, during life, saw very distinctly. These cerebra differed in nothing from those shown by Munk. It is then very probable that the extirpation

[2] Allis, Oscar H. Deformity from Fractures of the Humerus. Annals of the Anat. and Surg. Society. 1880. p. 289.
[3] George R. Fowler, Annals of the Anat. and Surgical Society, Brooklyn, N. Y. 1880. p. 309.

of the occipital lobes does not always produce blindness. This view seems paradoxical, and in contradiction, at first sight, with the law of causality, but it must be remarked that the brain is an organ whose functions are still largely in the domain of hypothesis; and variations of greater or less importance in both structure and function have been proved. Thus it is that aphasia is determined sometimes by lesion of the left inferior frontal lobe, and sometimes by lesion of the right inferior frontal lobe; there exists also cases in which decussation of the pyramidal columns has not been found. Munk's dogs were blind, but in these cases Munk himself has acknowledged that there was atrophy of the optic nerves.

Must we deny the law of Gudden, which says that lesions of the cortex never determine lesions of the peripheral nerves, or must we admit that Munk removed something besides the cortex?

The animals observed by Munk also presented functional lesions of certain parts of the retina. Here, again, the question comes up: was not the visual trouble of these dogs due rather to lesion of the attention than of the faculty of vision? Munk's scheme, according to which the cerebral cortex of one side is connected with half the visual field of both sides, has been combated by Luciani, who has obtained the same visual troubles, whatever part of the cortex was extirpated.

Exner finally makes allusion to the little knowledge which we possess respecting the cerebral localization of the other senses; he remarks that almost all the physiologists who have wrought at this question admit that there do not exist strict and well-defined localizations, but that the different centres are inter-connected, each at the same time presenting a region more especially rich in nerves and nerve-fibres pertaining to a certain function.

The report of the Physiological Section of the German Naturalists and Physicians at the meeting in Berlin last September (*Deutsch. Med. Wochr.*, No. 40, 1886), shows not only great differences of opinion in regard to cerebral localizations, but of interpretation of the results of experiments upon animals. In fact, some of the meetings were quite stormy, and it was apparent that anger may possess the minds of physiologists as of celestials.

DIET IN FEVERS.

AT the meeting of the Society of Therapeutics, Paris, October 13th, 1886, Dujardin-Beaumetz read a communication on "Diet in Febrile Maladies" which was of a practical nature, and elicited considerable comment.[1] He recalled to the minds of those present that after the memorable discussion of this subject at the Society of the Hospitals thirty years ago (in 1857) the rigorous diet heretofore imposed upon fever patients was abandoned, and a more generous alimentation adopted, especially in typhoid fever. Trousseau, Monneret, and Hérard were prominent advocates of this new dietetic treatment of fevers. On what basis may a rational alimentary regimen in febrile maladies be established? If we take into account the average waste, that is, the daily loss of weight, the need of reparative alimentation is apparent. According to Layton's figures, a typhoid fever patient loses weight at the rate of two hundred and thirty-nine grammes a day, though the waste is often greater than this. But however abundantly nutriment may be provided, it is not certain that much will be assimilated. In typhoid fever (which may be taken as the type of fevers), the lymphatic network of the intestines is the seat of an inflammation which opposes absorption. The chyle, (that is to say, the fatty substances and the peptonized albuminoid matters), will not then find its way into the circulation by the lacteals and thoracic duct, and it is only by the radiates of the portal vein that aqueous and saline substances can get into the system.

Moreover, the labors of Bouchard, of Lépine, of A. Robin, have shown that in the febrile process there is an accumulation in the economy of the products of organic disintegration, and that it is desirable to facilitate the excretion of these toxic products.

From all this it results, according to this view, that in febrile states, and in particular, in typhoid fever, the digestive tube is not in a fit condition for the absorption of albuminoids and fats, and the economy is poisoned by the débris of organic disintegration. Dietetics have but a limited role in these cases, since only liquid and saline substances can penetrate the economy at the same time that the patient's own fat and muscular tissue is consumed by the febrile process.

As to the kinds of food most likely to be appropriated, it may be affirmed that the broth and milk which we are in the habit of administering to our typhoid patients enable us to introduce on the one hand a great quantity of water, and on the other certain saline substances. In the typhoid patient there is a veritable *inanition* of mineral matters, resulting from the daily losses in potassium, in sulphuric acid, in phosphoric acid, and chloride of sodium, products of disassimilation which pass off by the urine, and which attain the figure of three to four grammes of chloride of sodium, one and one-half to two grammes of phosphoric acid, 2.967 grammes of sulphuric acid, and 1.730 grammes of potassa. Broth seems best to fulfil the desideratum, for it contains little besides water and salts.

Is it the same with milk? This question may to a certain extent be answered in the affirmative. By the water and saline ingredients it contains (and which latter resemble those of serum), milk very well responds to the indication for a liquid and saline nutriment in febrile diseases. But milk contains albuminoids and fats besides. What part do these play? Do they act as food, or are they rejected, without being absorbed. We are entirely ignorant, and careful experiments, made by daily weighing typhoid pa-

[1] Bull. et Mém. de la Soc. de Thér., October 20, 1886.

tients fed exclusively with beef tea and broth, and such as are fed exclusively on milk, might, perhaps aid in throwing some light on this question. Such experiments Beaumetz is instituting in the Cochin hospital, while inclining to the opinion that milk in typhoid fever has a nutrient value only by reason of the salts and water which it contains. As for wine, he believes that it has a general tonic effect, besides being a waste-restrainer.

In the discussion which followed the reading of the paper of which the above is an abstract, Blachez remarks that, if it were well proved that fever patients do not assimilate albuminoids, it would be useless to give them a nutriment so rich in albuminoids as milk.

Catillon thought that alimentation by broth was an illusion. Corville and Bochefontaine in their experiments on dogs have shown that these animals when fed only on broth waste quite as fast as those to which nothing but water is given. As for the organic combustions, they are not always in relation with the excretion of urea, which may augment while the temperature remains normal.

Ernest Labbée remarked that it was a custom of Monneret to give his fever patients six quarts of liquid nourishment a day. This he regarded as excessive alimentation, forcing into patients more liquid than they like to take, and imposing on the kidneys too heavy a task of elimination, whence renal congestion and albuminuria are likely to result. He thought that four quarts of liquid a day should suffice.

Cadet de Gassicourt was of opinion that the scales would enlighten us as to the value of milk in the diet of typhoid fever patients; by daily weighing our patients we should find whether they lose as much weight when fed on milk as on broth, or whether there be a difference in favor of milk.

Bucquoi regarded it as a matter of indifference whether milk or broth be the diet of typhoid patients, for during the active stages of the fever (periode d'état), these patients cannot assimilate the nutritive elements of either the one or the other. Perhaps even the medicines we give are no better absorbed.

Crequy observed that if milk were not absorbed in typhoid fever, the casein would appear in the stools in the form of curds, which in his experience was not often the case.

Ernest Labbée replied to the remark of Bucquoi concerning medicaments, that we have proof that certain medicines, as quinine and antipyrine are absorbed, for we note their physiological effects; quinine, moreover, has been found in the urine.

Campardon observed with reference to the absorption of salines, that it is a fortunate circumstance that these substances are so readily assimilable they promote diuresis, and thus purify the organism by more rapid elimination of effete products. Bucquoi, thought that to be consistent, Dujardin-Beaumetz ought to replace milk by whey in the alimentation of his typhoid patients.

Cadet de Gassicourt closed the debate by saying that the suggestive communication of Dujardin-Beaumetz brings before us questions of very great importance. We have now to ask ourselves if all that we can do is simply to subject our fever patients to an aqueous, saline diet (as seems probable from the new physiological considerations which have been advanced), or whether we can sustain their forces and check too rapid waste by a suitable strengthening alimentation. The question cannot be solved by discussion or speculation, but by direct and accurate experimentation.

INCREASE OF INSANE AND PAUPERS IN NEW YORK.

A special meeting of the State Board of Charities was held at Albany, December 9 and 10, for the purpose of considering the annual report. The report shows a slight increase in the pauper and reformatory classes, and a large increase in the number of the insane, the various asylums of the State having 13,533 insane persons in their care on October 1st, 1886, as against 12,707 at the same date in 1885. These institutions are generally crowded, and there is urgent need of increased accommodations for this class.

At the same time, the report points out the importance of more stringent measures for the prevention of the shipment of the insane or otherwise infirm paupers into New York from other States and countries.

One of the most important questions to which the Board has directed its attention during the year is the desirability of a more practical industrial training of the youthful wards of the State, especially girls and young women; and at the recent meeting, measures were adopted for bringing the matter prominently to the notice of the managers of orphan asylums and all other public institutions having charge of female children.

MEDICAL NOTES.

— It appears that her gracious majesty, Victoria, was nursed at the breast of her mother, the Duchess of Kent, and that she herself performed the same maternal office for each of her nine children. But then, of course, the outside duties and engagements of a queen are much less onerous than those which oblige so many women of society to delegate such homely duties to a menial.

— The *Archives of Pediatrics* (July, 1886), contains a good word for salicylate of sodium in infantile diarrhœa. A prominent factor in all cases of infantile diarrhœa, if indeed not the chief factor, is that fermentation has taken place in the course of the alimentary tract, and the motions are constantly therefore acid, extremely offensive, and full of undigested milk. To prevent this fermentation should be the first aim of treatment. With this object, Dr. Shank recommends salicylate of sodium as being at once an antacid and a powerful antiseptic, and, what is of great

moment, a medicine easily administered to a child. He gives one grain every three hours to a child a year old. If there is much vomiting he adds a fourth of a grain of calomel to each dose, and small quantities of opium if there is much pain.

— The Chinese have a rather radical cure for cholera. A Shanghai paper says that on July 22d, a Chinaman employed on one of the steamers was taken ill, apparently with cholera. The following is the course which was adopted, according to the paper from which we quote: "His friends immediately sent for a native doctor. This individual had with him a box containing some long needles, and these he used on the patient. A needle was driven some distance into the man's head, near each temple, and again behind his ears. In each case bleeding followed. Needles were also driven into the lips, both sides of the chest, both sides of the stomach, and also into the pit of it. The doctor then scraped the skin of the man's throat till it looked like the neck of a turkey. This violent treatment had the desired effect, and in a few hours afterwards the man was quite well, and eating his midday meat with evident relish."

In a recent number of the *Berliner Klin. Wochenschrift*, a remarkable case is recorded by Dr. Wolf of Goritz, of poisoning by the medicinal administration of iodide of potassium; the amount of the drug taken was no more than four tablespoonfuls of a three per cent. solution in about thirty-six hours, and the purity of the drug was shown by chemical analysis. The patient was suffering at the time from subacute kidney disease of about three months' standing, and cardiac hypertrophy, which facts we must bear in mind in estimating the idiosyncrasy. After the administration of four tablespoonfuls of the above-named solution, the face became swollen and covered with pustules, papules, and bullæ, and twenty-fours after the mucous membrane of the mouth, pharynx, and alimentary canal became attacked in a similar manner. On the cessation of the drug no amelioration ensued, and in eight days the patient sank into a state of collapse and died. No necropsy was made. A similar case was recorded by Morrow, in which the administration of the drug to a person suffering from renal and cardiac disease caused an eruption resembling pemphigus, with similar symptoms and result.

NEW YORK.

— At the annual meeting of the New York State Veterinary Society, which was held at the American Veterinary College on December 15th, the following officers were elected: President, Dr. W. H. Pendry; First Vice-President, Dr. Theodore Birdsall; Second Vice-President, Dr. George Brown; Secretary and Treasurer, Dr. W. E. Cuff.

— The annual meeting of the Society of Medical Jurisprudence and State Medicine was held December 9th, when the following officers were elected: President, Amos G. Hull, Esq., Vice-President; Dr. E. A. Harwood; Secretary, Dr. E. C. Spitkza; Assistant-Secretary, Dr. J. F. Chauveau; Treasurer, Dr. R. C. M. Page. Mr. W. H. H. Russell presented the report of a committee which had been appointed to devise means to aid the Health Department in suppressing the manufacture and sale of unwholesome or adulterated food. The report urged the appointment of four additional inspectors of milk, nine of meat, six of fruit, and one of fish; and the recommendation was opposed by Drs. Leale and Spitzka, who contended that the Board of Health already had sufficient inspectors to do the work required of them.

— The Governor has appointed Mr. Thomas Newbold, of Poughkeepsie, recently a State Senator, and Dr. Maurice Perkins, of Schnectady, Professor of Chemistry in Union College, members of the State Board of Health, to fill the vacancies made by the retirement of Dr. E. M. Moore, and the death of the Hon. Erastus Brooks.

At a meeting of the board of Health held December 16th, a reply was formulated to the criticisms of the Commissioners of Accounts, and sent to the Board of Estimate, in the course of which they assert that the expenditures for salaries were incorrectly stated by the Commissioners; that the actual amount of the unexpended balance of the appropriation for the year 1886 may be regarded as caused by the small amount employed for disinfection last summer; that the standard of qualifications of additional sanitary inspection has not been lowered, and that the statement of the Commissioners that hardly fifty per cent. of the Board's primary orders are complied with, is disproved by the records, which show that between July 1, 1885, and July 1, 1886, of 19,490 such orders issued, 18,732 were complied with.

— On December 13th, when the Board of Estimate and Apportionment were engaged in finally settling the amount of the appropriation for the Health Department for the coming year, a communication was received from the Commissioners of Accounts, in which the management of the latter was severely criticized. A portion of it is as follows: — "The department has undoubtedly many serious obstacles in its path, not the least of which perhaps are its defective laws, and yet we cannot resist the conviction that notwithstanding the inperfection of the law, it falls far short of what it might be under a capable, vigorous and experienced head. Its system of business is too circulatory and expensive. There is too much formality and too little out-door work of an aggressive and effective kind; the lax policy which obtains in regard to the enforcement of original orders tends to bring the authority of the department into contempt. Hardly fifty per cent. of its primary orders are carried out. Inspections and reinspections of a single case occur until they are numbered by scores and entries thereof on the book by hundreds. The policy now pursued is the reverse of that which obtained in the early history of the department."

PHILADELPHIA.

— The College of Physicians will celebrate the centennial anniversary of its organization on Monday, January 3d. The President of the College, Dr. S. Weir Mitchell, will deliver a commemorative address at Association Hall, Monday evening, which will be followed by a reception. Tuesday evening, the President and Fellows will give a dinner at the Assembly Rooms of the Union League Club. It is understood that many of the vacancies in the associate membership will be filled by the election of distinguished members of the profession in other parts of the country.

Correspondence.

MORE SEVERED DIGITS.

FORT TOTTEN, DAKOTA, Dec. 16, 1886.

MR. EDITOR, — I have just read Dr. I. F. Galloupe's letter in your issue of November 25th, in regard to severed digits, and send you a report of the following case, which occurred in my practice.

Private Charles Tomlison, Company "F," 17th Infantry, reported to me on the 2d of October, 1885, with about half an inch of the tip severed from the ring finger of his left hand. He stated that he had just met with the accident while cutting wood at his company quarters, about three hundred yards away. As he did not bring the severed piece of finger with him, I sent some one to look for it at the wood-pile, and after, perhaps, twenty minutes, it was found and brought to me. I carefully washed it in tepid water, replaced it on the stump, secured it by means of strips of plaster and hermetically sealed the dressing with collodion.

No other dressing was used, and in a little more than a month the piece had freely reunited. Ultimately the sensation was almost entirely restored. I forgot to mention that the cut was a clean one. Respectfully yours;

A. A. DELOFFRE, *Asst. Surg. U. S. A.*

COMMITTEE FOR COLLECTIVE INVESTIGATION, INTERNATIONAL CONGRESS.

110 W. 34TH ST., NEW YORK, Dec. 19th, 1886.

MR. EDITOR,— In the session of the International Medical Congress, of Copenhagen, I was appointed the American member of the Committee for Collective Investigation, and permitted to select a colleague in the United States. Thus the pamphlets and circulars prepared by, or with the authority of, the General Committee in London, were distributed under the names of N. S. Davis, and the undersigned. They were made returnable to my address, on January 1st, 1887.

As I have resigned my position on the above committee, I require the permission and privilege of notifying, through your Journal, the holders of the above pamphlets, that they ought to be sent to N. S. Davis, M.D., 85 Randolph Street, Chicago, Ill., instead of the undersigned.

Very respectfully, A. JACOBI, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 11, 1886.

Deaths reported 2,055: under five years of age 760: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 395, lung diseases 316, consumption 262, diphtheria and croup 166, measles 82, typhoid fever 52, diarrhœal diseases 35, malarial fever 23, scarlet fever 11, whooping-cough 10, cerebro-spinal meningitis seven, erysipelas seven, puerperal fever two From diarrhœal diseases, New York 18, Philadelphia nine, Boston, District of Columbia, and Fall River two each. Nashville and New Bedford one each. From malarial fevers, New York 15, Baltimore four, Philadelphia three, Charleston one. From scarlet fever, New York six, Philadelphia two, Baltimore, Pittsburgh and Worcester one each. From whooping-cough, New York and Lowell three each, Philadelphia two, Boston and Baltimore one each. From cerebro-spinal meningitis, New York five, Philadelphia and Baltimore one each. From erysipelas, New York four, Boston, Pittsburgh and Nashville one each. From puerperal fever, Boston and Pittsburgh one each.

In the 19 cities and greater towns of Massachusetts, with a population of 967,534 (population of the State 1,941,465), the total death-rate for the week was 23.06 against 18.14 and 16.64 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,093,817, for the week ending November 27th the death-rate was 20.2. Deaths reported 3,529: infants under one year of age 825; acute diseases of the respiratory organs (London) 413, measles 144, scarlet fever 75, whooping-cough 54, fever 55, diphtheria 37, diarrhœa 35.

The death-rates ranged from 13.4 in Brighton to 29.5 in Norwich; Birmingham 16.6; Bolton 17.8; Bradford 19.4; Hull 20.2; Leeds 23.1; Leicester 20 9; Liverpool 21.8; London 19.4; Manchester 22.0; Nottingham 18.2; Sheffield 21.5; Sunderland 15.6.

In Edinburgh 18.9; Glasgow 25.4; Dublin 25.3.

For the week ending November 27th, in the Swiss towns, there were 32 deaths from consumption, lung diseases 18, diarrhœal diseases 18, measles four, diphtheria and croup four, whooping-cough two, erysipelas one.

The death-rates were: at Zurich 17.2; Geneva 12.1; Basle 16.3; Berne 9.6.

The meteorological record for the week ending December 11, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps: —

Week ending Saturday, Dec. 11, 1886.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 11, 1886, TO DECEMBER 17, 1886.

WILLIAMS, JNO. W., major and surgeon. Ordered for duty at Jackson Barracks, La. S. O. 205, Division of the Atlantic, December 14, 1886.

POPE, B. F., major and surgeon. Relieved from duty in the office of the Surgeon General of the army, and will report in person to the president of the Army Medical Examining Board in New York City, for duty as member and recorder of the Board. S. O. 285, A. G. O., December 9, 1886.

POPE, BENJ. F., major and surgeon So much of S. O. 285, A. G. O., December 9, 1886, as directs him to report in person to the president of the Army Medical Examining Board, New York City, for duty as member and recorder of the Board, is revoked. S. O. 287, A. G. O., December 11, 1886.

CORSON, JOS. K., captain and assistant surgeon. Leave of absence extended seven days. S. O. 288, A. G. O., December 13, 1886.

BARROWS, CHARLES C., first lieutenant and assistant surgeon. Granted leave of absence for two months, to take effect when his services can be spared by his post commander. S. O. 285, A. G. O., December 9, 1886.

WILSON, GEORGE F., first lieutenant and assistant surgeon. Granted leave of absence for one month, with permission to apply to headquarters, Division of the Missouri, for an extension of twenty days, to take effect about December 15, 1886. S. O. 125, Department of Dakota, December 1, 1886.

BALL, R. R., first lieutenant and assistant surgeon. Ordered for duty at Fort Riley, Kan. S. O. 144, Department of Missouri, December 13, 1886.

SOCIETY NOTICE.

NORFOLK DISTRICT MEDICAL SOCIETY. — A meeting for Scientific Improvement will be held at the hall of the Roxbury City Guard, 67 Warren Street, Roxbury, December 28, at 7.45, P.M. Communications: I. "Insomnia," Samuel G. Webber, M.D. The discussion will be opened by Albert B. Robinson, M.D. II. "Convulsions of Children," Herbert W. White, M.D. The discussion will be opened by Orville F. Rogers, M.D., and Edward T. Williams, M.D. III. "Exhibition of a Human Fœtus of Three Months," Allen Burdick, M.D. IV. "Exhibition of a Human Fœtus of Two Weeks," Jas. C. D. Figeon, M.D.

S. ALLEN POTTER, M.D., *Secretary*.

APPOINTMENT.

Edward Reynolds, M.D., has been appointed assistant in Obstetrics in the Harvard Medical School.

BOOKS AND PAMPHLETS RECEIVED.

Sixth Annual Report of the State Board of Health of New York. Transmitted to the Legislature, March 19, 1886.

The Relative Influences of Maternal and Wet-Nursing on Mother and Child. By Joseph Edeil Winters, M.D., New York. New York, 1886. (Reprint.)

American Pharmaceutical Association. Preliminary Draft of a National Formulary. Reprinted from the Proceedings, Vol. 34, 1886.

An Epitome of the Newer Materia Medica. Standard Medicinal Products, and Fine Pharmaceutical Specialties. Introduced and manufactured by Parke, Davis & Co. Fourth edition. Revised and enlarged. 1886.

Massachusetts Institute of Technology. Twenty-Second Annual Catalogue of the Officers and Students, with a Statement of the Courses of Instruction and a List of the Alumni, 1886-87. Boston, 1886.

Conference of the American Shipping and Industrial League, held at Pensacola, Fla., November 10-12, 1886. Address on Relation of Quarantine to Shipping Interests. By Joseph Holt, M.D., President, Board of Health, State of Louisiana.

The Microbic Revolution in Surgery. An Address Introductory to the Fifth Session of Lectures, in the College of Physicians and Surgeons, of Chicago, delivered September 21st, 1886. By D. A. K. Steele, M.D., Professor of Orthopedic Surgery. Chicago, 1886. (Reprint).

The Science and Art of Obstetrics. By Theophilus Parvin, M.D., LL.D., Professor of Obstetrics and Diseases of Women and Children in Jefferson Medical College, etc. Illustrated with 214 wood-cuts and a colored plate. Philadelphia: Lea Brothers & Co. 1886.

Cataract Extraction without Iridectomy. Paper read before the San Francisco Medical Benevolent Society, November 22d, 1886. By Geo. H. Powers, A.M., M.D. (Harvard), Professor of Ophthalmology and Otology in the University of California. San Francisco, 1886.

Lecture.

THE BEST EQUIPMENT FOR MEDICAL STUDY.[1]

BY FREDERIC HENRY GERRISH, M.D.,
Professor of Anatomy in Bowdoin College.

One of the chief objects of the American Academy of Medicine is "to encourage young men to pursue regular courses of study in classical and scientific institutions before entering upon the study of medicine"; in other words, we declare that a college education is a particularly desirable prelude to the pursuit of medical science. But the training afforded in different institutions of this class is by no means the same. In one the classics are given especial prominence; in another, the sciences; in a third, mathematics or the modern languages; and, while we recognize the value of a knowledge of each of these studies, we cannot fail to see that the preparation of men coming from one college more adequately fits them to acquire a medical education than that possessed by the graduates of another. Thus, though we are glad to find the prospective medical student decorated with the baccalaureate degree from any respectable institution of learning, because such discipline as he presumably has had has qualified him in large measure to appreciate and profit by the teachings of the medical schools, we are usually justified in regretting some features of his course, and in wishing that other subjects had been taught in their stead.

The Academy, however, has never expressed itself definitely upon this very important topic. In few of the colleges of this country have courses been established with especial reference to the preparation of young men for medical study; and clearly, only a small proportion of those who are ambitious to qualify themselves in this regard can attend these institutions. But, in most other colleges, the elective system is so far established that the student has a generous range of studies from which to choose, and can nearly, if not completely, adapt his curriculum to any scheme which this society may recommend. An obstacle to the practical working of the plan is the fact that so many young men develop no definite preference for one profession or another until an advanced period in their college course. Some, however, and, in the aggregate, a very large number, determine early upon a medical career, and to them the advice of the Academy will be of great value.

It may be objected that it is unwise to attempt to bend a youth's thoughts in the direction of his life's work while yet he is in college; that he needs the training which shall discipline his mind in all its parts, so that it may be prepared to do any task that shall be set for it.

To this the answer is made that the plan proposed, while believed to be particularly adapted to the requirements of the future medical student, has in it nothing essentially professional, and is so proportioned that it provides for the symmetrical development of the intellectual and moral faculties. Every one of us would deplore a preparatory education which would make a man one-sided in any respect. We all recognize the necessity of the humanities as well as of the sciences; and no education can be regarded as liberal which omits either of them.

[1] Read before the American Academy of Medicine at its annual meeting, October 12, 1886.

The purposes of this paper are, first and principally, to indicate in what branches and by what methods the student will find at once the most wholesome training for his mind, and the furnishings which will best equip it for medical study; and, second, to propose a minimum standard, which every student should be obliged to attain before being admitted to the study of medicine.

THE PROPER STANDARD.

First, in order of importance, is a knowledge of the English language, a tongue so generous in its hospitality that it welcomes to its adoption any word, whatever its nationality, provided it gives a reasonable promise of usefulness; so flexible, that a writer who besprinkles his page with foreign expressions is immediately suspected of an insufficient acquaintance with his vernacular; so strong, that it seems destined to develop into the universal speech. Without a complete knowledge of it, the student cannot understand the text-books he reads, or the teachers to whom he listens; he is unable to communicate to others his own thoughts, and, as a practitioner, his observations, though possibly of value on account of his native aptitude of perception, will fail to receive the recognition they merit, from the slovenly, crude, and obscure manner in which they are presented. We too often see illustrations of this fact in our medical journals; and still more frequently we meet men of great original ability, whose keenness has detected some new peculiarity of a disease, or some curious and unrecorded action of a medicine, or whose ingenuity has devised an improvement in surgical therapeutics, who are restrained from publishing their discoveries by an overwhelming sense of inability to report them properly.

A schooling is radically defective which does not include a steady, persistent, long-continued drill in English; constant exercises in reading the best writers in prose and verse, for the sake of acquiring elevation of taste and purity of style; daily practice in definition and the use of synonyms, in order to enlarge the vocabulary and give precision to diction, and, consequently, accuracy to thought; and frequent tasks in composition, that facility in written expression may be gained, and the pen become a fleet and willing assistant, instead of the slow and reluctant slave, which it is to so large a number of physicians.

Immediately suggested by these rhetorical exercises, because inseparably associated with most of them, is the matter of penmanship. It is not necessary that a physician should perform like a professor of calligraphy; but he ought, at least, to write with absolute distinctness. A short time ago there appeared in a prominent medical weekly a paper on abdominal section, and in it occurred this remarkable statement: "In Battey's operation the brains are removed: in Tait's the brains and the tubes." Who can blame the compositor for a mistake in a report so badly penned that "ovaries" looked like "brains"; and who would waste sympathy on an author who took so little care to make his manuscript legible? But the worst thing about a physician's bad penmanship is in connection with his recipes. A reference to the prescription-file of any apothecary will sadly confirm this statement. Nothing but long familiarity with such scrawls can enable the pharmacist to decipher the hieroglyphs, and one shudders at the thought of having such documents fall into the hands of a compounder whose imagination has been but slightly

tutored, and whose experience is limited in the interpretation of cabalistic characters. A mistake of the type-setter, made in consequence of the illegibility of the copy, is usually productive of no worse a result than anger on the part of the author and amusement among the readers of the article; but an error of the apothecary on such an account may bring a valuable life to an untimely end. In prescriptions the writing should be so distinct that no word or symbol can possibly be mistaken for any other. Every letter even ought to be well defined; and that there may be no lapse from clearness on these important occasions, it is best to write plainly at all times. The chirography of certain physicians is almost homicidal.

Closely allied to writing is the much rarer accomplishment of drawing. The same faculty which enables a person to learn to write, if cultivated a little more, makes him something of an artist. Any one who has compassed the difficulties of penmanship can learn to draw — not well, perhaps, but sufficiently to give him a pronounced advantage over his neighbor, who knows nothing about the art. One who has no facility with the pencil but faintly appreciates the usefulness of such skill; while he who can sketch, even though it be but little, hardly sees how he could do his work without the assistance of this ability. All through student-life occasions are continually arising in which the helpfulness of the pencil is very apparent: the arrangement of the apparatus on the lecturer's table, the shape of a leaf or flower, the form of a crystal, all are originally represented, and afterwards recalled, much more readily than by any description in words; and the busy doctor, anxious to preserve the memory of a peculiar case — a tumor, a monster, a malformed limb, a crooked back, a misshapen member of any kind — sketches it into his note-book in three minutes, and has it secured for future use, while the record, which he intends to make as soon as he gets time, is never written. The power to draw should be so common as to cease to be considered an accomplishment.

Mathematics require attention. The necessity of a knowledge of arithmetic is too obvious to call for lengthy explanation: without it, no step can be taken towards the higher grades, and the simplest problems involving number are incapable of solution. But the mathematical training must not be allowed to stop at the point where the grammar school leaves the pupil. Many questions in his subsequent course will admit of no comprehensible answer without the help of algebra; and, for the understanding of certain points in physics which find a place in physiological investigations, even the calculus is necessary. Geometry is the key to so many chambers in the halls of natural philosophy that we cannot omit it from our curriculum.

An acquaintance with geography, both political and physical, is more important to a medical student than would at first appear. Deprived of its aid, the whole science of climatology would be a closed book, and, at the present time, this department of knowledge is developing to such an extent and in such lines as to be of peculiar value to physicians. We are learning more and more that certain diseases are produced or, at all events, greatly favored by particular climates and in especial localities, and that other regions are singularly exempt from disorders which prevail elsewhere. All these facts have a marked interest in a most practical direction, and require for their comprehension a familiarity with the conformation of the earth's surface, and the differences of its conditions and productions in various parts.

We come next to consider the study of languages other than English. And first of all start up the claims of Latin. Nowadays it is becoming fashionable to decry the study of ancient languages. They are spoken of as superfluities, nearly, if not quite, useless, and sometimes, if not usually, harmful. With such opinions I have little sympathy. It may well be admitted that, up to a recent date, a disproportionate amount of time has been by many spent upon the classics, to the exclusion of scientific branches which are almost as useful in giving discipline to the mind, and serve better to prepare one for the practical work of life. But the fact that an undue importance was assigned to the classics formerly is no reason for our refusing to recognize any good in the study of them, even in the preparation for scientific pursuits. We should remember that just this berated classical training gave the world as splendid an array of medical men as has ever been seen — intellectual giants, who thought they saw one reason for their success as scientific physicians and surgeons in the thorough drill they had experienced in the dead languages.

There are certain bald facts which stand up persistently and demand recognition. One is that Latin enters largely into the composition of every modern language which it is of importance to the medical student to know, and that an acquaintance with Latin renders the acquisition of any one of these tongues a comparatively easy task. Another prominent and essential fact is that the nomenclature of every science is based directly on Latin or Latinized Greek, and the more one knows about these languages, the better will be his appreciation of the terms he uses, and the greater his ability to employ them correctly. There is less necessity for a familiarity with Latin now than formerly, when all medical works were written in it; but the time will never come when any other tongue will be chosen as the universal basis of scientific terminology, for Latin is, as it were, crystallized, and is not subject to the changes which modern languages are constantly undergoing.

How much of this language should be required as a preliminary to medical study is a question about which there is room for difference of opinion. An eminent teacher has declared that a student can learn in two weeks all the Latin he needs in his medical education. Possibly this is true in the case of a very active mind, but it does not follow that it would not be far better for him to study it a much longer time. Probably the pelts of two sheep would give any one of us sufficient covering for his nakedness and protection from the weather, but we never think of restricting ourselves to apparel of this primitive character. We know that our comfort, convenience and means of usefulness are all augmented by wearing raiment produced by the application of ingenuity, skill and labor to this original material. Our clothing costs more, but it is worth the increased price. Just so with the study of Latin; a little will give a scanty help, enabling the student to understand the ordinary variations in the forms of words, so that, for instance, he will not use singulars for plurals, or nominatives for genitives; it will show him how to frame a prescription grammatically; and it will give him enough of a vocabulary to save him from the grossest blunders in his recipes. But he will

never be able to use the language in any but this mechanical way; he will grope and stumble among his scientific terms, failing to recognize the kinship between nearly related words, obliged to learn arbitrarily by itself every new name, struggling against difficulties which, to one who is better equipped, are no longer obstacles, but pleasures. Any one who has had much experience in teaching medical students must have noticed the difference in the relative ease with which the terminology of medicine is acquired by those who have, as contrasted with those who have not, had a careful drill in Latin.

The student, then, ought to have such a command of the language as will enable him to read simple Latin with tolerable facility, and this can be gained, under competent instructors, by the time he has read Cæsar's Commentaries, a few of the orations of Cicero, and five or six books of Virgil. The teaching ought to be directed not mostly to the memorizing of rules of grammar, though something of this is unavoidable, but it should be addressed mainly to obtaining a mastery of the vocabulary, and the proper use of the language in expressing thought. In other words, Latin should be taught in much the same way as are Italian and Spanish, as if it were a living rather than a dead tongue, as nearly as possible as the Roman children were instructed in it. Thus, it would cease to be regarded as a shrivelled corpse, dry, cold and repulsive, and would seem to be fresh, and warm, and instinct with life — delightful to study, and pleasant and easy to remember.

As regards Greek, a different verdict must be rendered. Admirable as it is in its symmetry, wealth and precision, probably most of the best educated physicians would agree that it has been of little help to them in any department of their life-work. It is true that very many words in medical nomenclature are derived from the Greek, but, before they are accepted, they are converted into Latin and baptized with new terminations. It is also true that, in the veins of all modern languages, there courses a strain of Grecian blood; but here, too, the influence of the Roman is dominant, and, with a knowledge of Latin, one is so well equipped for conquering a living tongue, that the additional assistance afforded by the Greek is insignificant as compared with its cost. With great veneration for Greek as a language and admiration for its completeness and beauty, I would require a medical student to know no more of it than enough to recognize and pronounce its words, so that he can make intelligent use of his dictionary.

In continental Europe, two countries are especially prominent for their activity in medical affairs. Forty years ago France was the great centre to which all flocked who desired to perfect their education, but her supremacy is yielded now to Germany, and Berlin and Vienna, instead of Paris, offer the chief attractions to one who seeks to round out the training of the American schools with continental observation. Still Paris is great in medicine, and continually there are emanating from her physicians instructions which are entitled to the admiration and respect of the world. Many of the articles in the French and German journals are presented to us in abstracts in our magazines, and many books are translated from both languages into English, but the great mass of the literature of these nations is never translated. Some of the most valuable of their works are so costly that American publishers dare not venture on their production. Emerson's remark that he would no sooner think of reading a work in the original, when he had a good translation, than of wading a river when there was a bridge to cross on, has a correct application where translation is laborious, but is worse than pointless to one who has a real familiarity with the language in which the book is written, for, however fine a translation is, it cannot convey in its entirety the impression of the original; a something, often eluding description, like the fragrance of a delicate flower, is lost in the passage from one to another tongue, just as the finest tea loses a certain deliciousness of flavor in its journey across the ocean. Thus, if a student does not know French or German, vast stores of knowledge are locked against him, and the occasional parcels, which are withdrawn for his benefit by men who have admission-keys, are liable to be somewhat battered and torn in the process.

But the student of the present should be able not only to read French and German, but likewise to speak them; for, though this country certainly presents wonderful opportunities for medical study and observation, the facilities of the European capitals are, in some directions, immensely superior to anything on this side of the Atlantic, and every physician of proper ambition, who has not already been abroad for study, longs to go. Unquestionably, the chief reason why many are deterred from making the pilgrimage to these Meccas of medical science is an inability to speak and understand their languages. The preliminary education should, therefore, include a reading and speaking knowledge of French and of German.

The human body being a machine, subject to all the influences which affect artificial mechanisms, as well as to others which are more subtile, an understanding of its action involves a knowledge of the forces which are continually at work in and about it. There is no function of the body which does not necessitate the expenditure of energy, and, therefore, the investigation of these processes requires an acquaintance with the science of natural philosophy. One can never study physiology intelligently without having learned much concerning the properties of matter, the mechanics of solids and fluids, electricity, heat, light, and sound. A single throb of the heart, the merest glance of the eye, even the movement of a cilium on a cell of epitheleum, presents problems to the physiologist which are incapable of solution except by the aid of natural philosophy. And, as disease is not an entity, but a process, a perversion of normal action, in order to comprehend its nature, the aid of the same science must be again invoked. Thus, physics must be given a place in the curriculum.

But these various operations of the human machine cannot be explained by natural philosophy alone. We find that new substances are constantly being formed in the body by the union of two or more which previously existed; and, on the other hand, a single substance is broken up into two or more unlike itself. Nothing can explain these processes but chemistry, and a thorough drill in the elements of this science is as essential to a mastery of physiology as is an acquaintance with physics.

Aside, however, from the utility of chemistry in leading the way to physiological knowledge, it is helpful to a medical student in a way entirely independent of this, and, after a fashion, almost as important. It

trains his mind into a habit of diagnosis, which is of the utmost value to him in his professional career. For example, in the laboratory he has presented to him a solution, containing an unknown substance, which he is to determine. He applies to a portion of the solution a certain test; no reaction occurs, and he knows from this that no member of a certain group of substances can be present. To another portion he adds a second reagent; again no change appears in the liquid, and a second group of bodies is ruled out. So he goes on, treating successive portions with different tests, continually narrowing the field of investigation, until a response is given, indicating that one of a certain group of substances is present. Then, pursuing still the same method, he eliminates one after another of the elements concerned, until but one is left, and his task is completed. How identical is this with the plan which the systematic physician pursues at the bedside of a patient, whose disease does not declare its character at once! The doctor first asks himself: To what great class of maladies does this case belong? The features of one class are absent; it cannot be that; there is no evidence of its membership in a second, so that may be thrown out of the question; and thus, by careful steps, he reviews the various divisions of the nosology, until he reaches a group to which the case must belong; and, finally, by rejecting all but one disease of the lot, he arrives at his diagnosis by exclusion. This exercise in chemical analysis is so productive of a close and accurate method of thinking, that the discipline which it gives a medical student is, perhaps, as valuable as the knowledge he gets from it.

Let it not be thought that I have forgotten that general chemistry is taught as a part of every medical course: the fact is too patent to be ignored. But the only excuse for its being there is simply that many, yes, most students, come to the schools without the smallest knowledge of this science. The professor of this branch must begin at the very foundation in instructing his class, for he knows that, if he presupposes any chemical information on the part of his hearers, his lectures will be unintelligible to them. Really, however, there is nothing medical about general chemistry, however much there may be that is chemical about general medicine. Its study, by right, should be pursued long before the youth reaches the medical school, that he may have a preparation for the physiological instruction there imparted to him.

The student of medicine should devote himself entirely, during his first year, to human anatomy and physiology — the sciences which treat of the structure and functions of that quintessence of dust, man. The human animal, however, is so complex an organism, and the operation of his various parts so intricate, it is desirable that the student who intends to investigate these things should have an opportunity to study simpler forms, passing, by gradual steps, from the lowest of living beings to the highest. Hence, plants should first be taken, as they are the most simply constructed of all things which are endowed with life. Their tissues are comparatively coarse, their organs readily observed, and their processes understood without difficulty; and, while there are vast differences between the highest of them and the lowest of vertebrates, the student cannot fail to observe the striking similarities of structure and function in the vegetable and man. Botany also, like chemistry, furnishes a capital discipline in differential diagnosis. In the analysis of a specimen, the series to which it belongs must first be determined, then the class of this series, next the sub-class of the class, the division of the sub-class, the order of the division, and so on, until the plant is, as it were, run down with merciless certainty. Here, again, we have diagnosis by exclusion, the most systematic, positive, and satisfactory of methods. Such training as this cannot fail to correct slovenly habits of thought, and establish in their stead methodical intellectual processes.

Proceeding upwards from the study of our humblest relations to the consideration of those which are higher in the scale of being, we come to the animal group, some members of which are so like vegetables that we hesitate to draw the line between them. The student should go step by step from those which have a simple to those which have a complex structure, ending with the vertebrates. To these he should devote prolonged and faithful labor, dissecting them carefully with the scalpel, scrutinizing their minute structure with the microscope, tracing the homologies between them and the members of inferior orders, and considering the philosophy of their architecture. Dry and wet specimens should be prepared, injections of vessels and cavities practised, and microscopic specimens mounted. This method is of advantage not merely because it gradually unfolds to the student, in a rational and comprehensive manner, the mysteries of animal anatomy, but also because it gives him expertness in the use of the implements of dissection and of the microscope — instruments which he must use so constantly in his medical course, and ought to use all through his career. The practice is gained, too, on material which is fresh, inexpensive, and easily obtained, whereas, without this experience, his first efforts, with all their wasteful mistakes, must be expended on human cadavera, which, in this country, are often stale, always costly, and generally difficult to procure.

It will be observed that, in all these branches where laboratory work is practicable, it is insisted on as essential to proper training. The student must perform the experiments in physics, analyze the chemical specimens, dissect the flowers and the animals, and mount the microscopical sections. Merely seeing these things done by his teachers, he has not half learned the lesson; actual contact with the fact, and many repetitions of the contact are indispensable to real acquisition.

In all of these studies, the student should be required to make copious notes of what he sees and does. The benefits of this procedure are numerous, but least among them I reckon the preservation of a record of his work. It is of little consequence that he or any one else should be able to ascertain subsequently what his experiments have been, unless they include original work,— a supposition which is wildly improbable; but it is of the greatest moment that, early in life, he should establish the habit of recording the details of his labor, so that, when he enters upon the practice of his profession, he may find it easy to keep an account of each case, and thus have at hand, for ready reference, an orderly accumulation of facts occurring within his own observation, a history of his experience, to which he can refer at any moment, refreshing his memory of former patients, who come again into his field of vision, collecting groups of cases, and tabulating the results of special lines of

work, to the great advantage of his clientèle, the instruction of his fellows, and the advancement of his own reputation.

A department of study to which little attention is paid, but of immense importance to a student, is logic, the science and art of reasoning. Unless he is practically familiar with the rules which cannot possibly be deviated from in sound reasoning, his mental operations are loose and heedless, and he is always exposed to the injurious results of his erroneous deductions. His observation of facts may be keen, his record of them religiously accurate, and his desire to reach the truth deep and enthusiastic; but, if he has not the training of a logician, his conclusions may be so wide of the mark as to make his efforts, at the best, unproductive of good, at the worst, pregnant with evil. Always are we hampered with the products of the bad reasoning of great men in our profession. One, to whom we look up as to an oracle, states a conclusion at which he has arrived, and we accept it as correct. Unable to repeat his experiences and relying on his wider opportunities, we adopt his recommendations, and, when we fail to achieve results like his, we blame our own lack of skill. After we have had years of disappointment, there arises another investigator, a man who has dared to think for himself, and he declares that the facts stated by the first teacher have been misinterpreted throughout, that really they are incapable of the construction which has been put upon them. The cause of our failure is now plain, and, disgusted by our bitter fortune, we are inclined to become sceptical about all the conclusions of all the leaders. If he who affected to instruct us had been trained to logical methods, we would have been spared the humiliation and grief which follow defeat, and our patrons would have escaped our well-meant but useless ministrations.

As the labor of no one of the learned professions requires more intellect than the medical, so also in none of them is there more need of a sound body. The unavoidable irregularity of his meals, the frequent disturbance of his sleep, his exposure to the inclemencies of the weather, and the anxieties by which a physician in active practice is constantly harassed, combine to form an array of depressing agencies which often overwhelm a seemingly invulnerable constitution. Consequently it is a necessity of the case that a young man entering upon the study of medicine should bring to his work a body that is free from disease and full of vigor and elasticity. However richly a youth may be endowed with these qualities, a failure to observe the laws of hygiene will undermine the glorious fabric and leave it a ruin. The physical training of a young man contemplating medical study should never be neglected. He should be taught early that the preservation of the integrity of his body is a duty which he owes to himself and his possible offspring — a duty which cannot be violated with impunity. He should be indoctrinated with the great truths of hygiene, and imbued with an ambition for high health. Thus he will come into the profession with unusual power to resist malign influences, and will be a physical delight to himself and a noble example to others.

Finally, though by no means least in importance, there should be embraced in the preliminary course of the medical student instruction in ethics. I intend no disparagement of any other calling in expressing my conviction that in no profession is there so great need of correct ideas of duty as in the medical. The physician meets his fellow-beings in relations more delicate and trying than those in which any other man is put. It is he who is made the confidant of youth and manhood and old age; who carries with him the secrets of prince and peasant; who sees the sufferings which are disclosed to none else. No other man is habitually exposed to temptations as terrible as his. The lawyer's work is subjected to the jealous scrutiny of an adversary; the clergyman is the constant target of hundreds of curious eyes; but the physician does his task in the privacy of the sick-room, with no competent critic standing near to inspect his performance. He can conceal his mistakes so cleverly that they are unsuspected; he can turn his bungling into reasons for his patient's gratitude; he can multiply remunerative visits far beyond the needs of his cases. His knowledge of the innermost histories of his patrons gives him a power over them which he can wield to his pecuniary profit. In such circumstances how essential it is that the physician should have clear conceptions of right and wrong! But in no other relation does the need of inflexible morality appear as conspicuously as in his association with women. He should ever bear in mind that it is not simply faith in his skill but confidence in his honor that induces women to place themselves in his professional care, and that a violation of this trust is worthy of, and will receive, the execrations of all decent men. It is impossible for a physician to be too scrupulous in his conduct toward the other sex. The preservation of purity of life and the cultivation of a genuine respect for the rights of others is a branch of the preliminary education which none can afford to neglect.

Doubtless the exactions of the plan presented in these pages will seem to many to be too severe. They will object that the scheme requires so great an expenditure of money and time that many young men of excellent talent and enthusiastic bent towards medicine will be excluded from the schools. But, if a boy of fourteen, robust and bright, who had already learned to read and write English, had mastered a common-school arithmetic, and had acquired a fair knowledge of geography, were to devote himself to the proposed course of study under good tutors, working only as much as is consistent with the maintenance of a high degree of health, he could cover the whole ground creditably in six years at the outside. No reasonable person would want a boy to attend a medical college before he was twenty years old, and unless I am grievously mistaken, the youth in question would be prepared for his professional course at that age.

This disposes of the question of time; next comes the criticism based on the money cost. Without doubt many who now go through our schools would find an insuperable obstacle in the necessity for a large outlay for a preliminary education, but the loss which the profession would sustain by their exclusion would not be serious. If a man of the right stamp really wants to be a physician, poverty will not keep him from entering the profession, and he will accept the preliminary requirements with a conviction of the correctness of the principle which underlies them. Those who rebel against these exactions have not in them the stuff that good physicians are made of.

It will probably be argued that some of the most brilliant members of the profession had but a scanty early education. Granted; but they were geniuses,

as few men are, and it would be absurd to make our rules with reference to such prodigies and their needs, rather than for the average man and his wants. Besides, such an education would be helpful even to a genius; the great John Hunter would have been improved by it, for it would have made him a better English scholar, at the very least.

Perhaps there are some who will consider the scheme too narrow. It may be said that a physician should be an accomplished gentleman, versed in literature, science and art, one whose very presence would be charming to the most refined and cultivated patients. It is readily admitted that no equipment is too good for a physician, but we must not expect impossibilities, and too exalted and variegated a standard might result in the production of a race of doctors like Talleyrand's, who knew "a little of everything, even physic."

THE MINIMUM STANDARD.

Of the great number of medical schools in the United States, comparatively few have a genuine entrance examination, and only a minority of these require more than a meagre grammar-school education. Many of the most prominent, influential and numerously attended institutions make no mention of the subject in their announcements, and recently one of the most celebrated took pains to state that no evidence of preparatory study was demanded, thus putting a premium on ignorance and unfitness. In other words, our medical schools largely assume an attitude which practically proclaims their belief that no preliminary study is necessary. The pitifulness and melancholy error of this position need no further presentation to this society.

If such a plan as that proposed in the preceding pages were to meet the approval of those having in charge the medical schools of this country, it would be impracticable to apply the system immediately; so great a change must be brought about gradually. That something of the kind will ultimately be done it is a pleasure to believe. But meantime it is evident that many intermediate steps must be taken. First, the managers of the schools must be persuaded that to encourage a person to pursue a course in medicine who has had little or no previous training and is ignorant of those branches which are the proper prelude to medical study is an act of injustice to the would-be student, of degradation to the profession, and of inhumanity to the community. Next, it must be proven to them that they have no right to throw the responsibility of the student's preparation upon his medical preceptor, as so many of them do, for the preceptor will not, as a rule, insist upon the pupils knowing any more than the schools require. Finally, the lowest preliminary requirements must be agreed upon, and religiously exacted at every school.

The remainder of this essay will be devoted to a statement of the minimum of attainments which medical schools should require of students before admitting them to the study of medicine, with such additional remarks as may be necessary to the elucidation of the subject.

In the first place, the student should have a thorough training in the branches taught in the common schools. It will doubtless strike many as absurdly superfluous that this requirement should be mentioned; they take it for granted that every man who aspires to be a physician has much more education than this. But such confidence betrays their lack of knowledge of the material with which medical teachers sometimes have to deal. If the matriculants in one of the metropolitan schools were to be subjected to a severe scrutiny as regards their attainments in this direction, developments would be made which would excite both mirth and pity. It would be found that many are unable to compose a business letter of moderate length without glaring mistakes in orthography and syntax; to give correctly the boundaries of the State of their residence; to solve a simple arithmetical problem; to read intelligently a news column of a daily paper. Occasionally one would be discovered whose skill is so severely taxed in making his autograph that he will misspell his own name. Extravagant as all this seems, it is merely a statement of actual observation. I have known a single candidate, who was nineteen years old, had attended school four years, and had studied medicine with his father, a physician in active practice, to give the following answers: Germany is in South America; Europe, Asia and Africa also are in South America; Russia is in North America, about five hundred miles from New York City; England is in Russian North America; New Orleans is north-east from Indiana; water freezes at thirty-three degrees below zero, and boils at one hundred and two above; the torrid zone is hotter than the frigid on account of climate; summer is warmer than winter because of temperature; all animals are called quadrupeds; mosquito is spelled m-o-c-q-t-o; if two apples cost three cents, twelve will cost thirty-six cents. It is one of the commonest experiences of the entrance examiner to read the essay of a man who has both a paucity of ideas on any subject that may be selected for his composition, and an almost utter inability to express the few notions he has with any approach to clearness or fulness, to say nothing of elegance or even accuracy. The vocabulary of some medical students is so limited that they not only cannot give intelligible utterance to their own thoughts, but cannot comprehend much of what is spoken to them in the lectures of their professors. How preposterous it is that such men should receive any encouragement to enter upon the study of medicine!

We must insist, then, upon a display of a competent knowledge of the fundamentals. The student must show that he knows his mother-tongue; that he can read English intelligently, hear it with understanding, and express ideas clearly in it; that he can write plainly; that he can make ordinary arithmetical calculations; and that the chief facts in political and physical geography are familiar to him. In addition to these, the elements of algebra should have been mastered; Latin should have formed such a part of his study that he can translate passages at sight from a Latin reader; and the foundation principles and leading facts of natural philosophy should be to him as household words. His body should be healthy and strong, his mind active, and his morals pure.

These preliminary requirements are scanty, indeed, but what a change in the character of the classes in our medical schools would take place, if they were to be enforced! The difference, moreover, would not be such merely as one would ordinarily anticipate, but would be much greater. The poorly-prepared, and those altogether without preparation would not venture to apply for admission, and many of those who

had undertaken to qualify themselves to the extent specified would perceive the enormous advantage of still further equipment along the same lines, and would extend their studies in the direction of a liberal education. This statement is not the result of a mere conjecture, but of observation of the practical working of such a rule.

Gradually the standard could be elevated; and, in less than a generation, the whole aspect of medical education in America would undergo a change of the most radical character. A chief obstacle is the desire of the faculties of medical schools to have large, and, consequently, lucrative classes. Each thinks, and with considerable reason, that, if it takes the step proposed, its classes will diminish below the paying point, and its rivals will acquire what it loses.

It seems to me that the Academy can exert a most healthful influence upon the medical schools of this land, and do much to convince their faculties that a genuine requirement of preliminary education should be enforced, and that such a standard as has just been explained is the least that will justify a physician or a school in permitting a person to enter upon the study of medicine.

THE TREATMENT OF PROLAPSE OF THE UTERUS AND VAGINA, ESPECIALLY IN THE AGED, WITH ILLUSTRATIVE CASES.[1]

BY CHARLES M. GREEN, M.D.

It is not intended in this paper to consider the treatment of those minor degrees of prolapsus uteri of such frequent occurrence during the child-bearing period, which are generally associated with anterior, posterior or lateral displacement, and complicated with, if not caused by, inflammatory changes in the parametrium. In these cases treatment is primarily directed to the removal of inflammatory exudations; and the use of pessaries, or the application of any operative procedure, is expressly contra-indicated until that result shall have been accomplished. But attention is invited to the consideration of a class of cases of less frequent occurrence, in which the uterus and vagina are wholly or in part without the vaginal introitus, — constituting in effect a genital hernia, the bladder and rectum usually sharing in the hernial protrusion. These cases occur chiefly in multiparous women advanced in years, still obliged to lead laborious lives; but they are sometimes seen in the nulliparous under favoring conditions.

Prolapse of the uterus and vagina originates principally in one of two ways:

a. The perinæum has been badly torn, and the anterior vaginal wall thereby deprived of the normal support of the perineal body: a cystocele thus developes. The recto-vaginal septum also bulges forward and downward. The descending vagina thus drags down the uterus, even though it be of normal size and weight until its position shall have induced secondary changes from disturbances of circulation: a frequent result of this traction on the uterus is an hypertrophic elongation of the cervix.

b. Frequent child-bearing, with insufficient rest in bed, has resulted in a condition of subinvolution both of uterus and vagina, and the consequent increase in the weight of the uterus unduly taxes the sustaining powers of the peritoneal folds which suspend that organ: thus the unsupported uterus descends by its own weight, and drags with it the vagina. Not infrequently the cervix has been badly lacerated, and has undergone hyperplastic changes which add to its size and weight. In the nulliparous, prolapse of the vagina and uterus may occur from the presence of uterine tumors, the enlarged and heavy uterus distending the vagina and finally dragging it into complete inversion.

While partial or complete prolapse may occur strictly in either one of the two ways above mentioned, it is probable that in most instances both factors are operative: the heavy uterus presses from above, and the descending vagina drags from below. Although the foundations of future trouble are laid during the child-bearing period, external protrusion often does not occur until after the menopause. Owing to the disturbed circulation of the prolapsing parts, the atrophic senile changes do not take place. A potent factor in causing genital hernia then becomes operative, namely, the enfeebled muscular tonicity of advancing years, the descent of the parts being favored in a manner analogous to the formation of intestinal hernia in old men.

Unless produced suddenly by some great strain or unusual effort, genital hernia is developed gradually from the causes above alluded to, and entails symptoms which usually lead the patient to seek relief before extreme degrees of prolapse have occurred. Such cases are, therefore, never seen among the well-circumstanced, except in those rare instances in which a morbid sense of delicacy has prevented the patient from taking advice until the extrusion of the parts has compelled her to do so. But among the laboring poor, accustomed to lift and carry heavy burdens, who often bear uncomplainingly the minor ills of life, and especially in the aged and neglected drudge, early symptoms are often ignored; and in this class, therefore, complete inversion of the genital canal is not infrequently seen. When the prolapse has reached any considerable degree, the inevitable attrition soon results in abrasions and ulcerations: want of cleanliness and the fetid discharge from sloughing tissues make the patient an object of offence to all about her. The usual displacement of the bladder renders the complete emptying of that viscus no longer possible, and the distress of cystitis is added to the discomfort and pain from the hernial protrusion. The condition of the patient is indeed pitiable: she can neither stand, sit, nor walk, is at last unable to work, and becomes a burden to herself and her family.

The treatment of these cases is usually most trying and unsatisfactory in ambulatory practice: after the digital reposition of the prolapsed parts, temporary rest in bed is generally indispensable to success in the application of any method of treatment. The means at our command, from which we are to choose according to the circumstances and indications of each case, are the astringent tampon, pessaries, and the various surgical procedures,— colporrhaphy, anterior and posterior, colpo-perineorrhaphy, amputation of the infravaginal cervix, removal of the uterus, shortening of the round ligaments, and the formation of cicatricial contractions of the vagina by the use of the thermo-cautery. Such of these measures as have been utilized in my own experience will be commented on *seriatim*.

[1] Read before the Boston Society for Medical Improvement, December 13, 1886.

The temporary use of the astringent tampon is a valuable antecedent to any method of treatment: by its means, the patient remaining recumbent, not only are the parts retained *in proprio situ*, but abrasions are healed, the circulation is improved, the drawn-out cervix is enabled to retract, and the uterus is often considerably diminished in size. These changes are materially aided by the depleting effect of glycerine, with which the tampons are moistened,— the copious watery discharge relieving the congested vessels. The astringent most applicable is tannin, and it is my custom to use it in a twelve and a half per cent. solution in glycerine. To be most effective the tampon should consist not of a single large wad of cotton, which may indeed retain the parts *in situ*, but of small pieces applied with care in such a way as to bring the medication in contact with every part of the vagina. Common carded cotton is preferable to the absorbent, being more elastic and less easily matted together. After from ten days to two weeks in bed, the patient may be allowed to sit up and walk about; and were it not that this method required the frequent services of the physician, the long-continued use of the tampon would be advisable in many cases not suitable for more radical treatment. Intelligent women may often be taught to make and use themselves a cotton ball of suitable size to retain the parts, when the uterus is not much enlarged, and when other measures are contraindicated. The value of the tampon is well illustrated by the following case:

Mrs. T., widow, seventy-two years of age, bore her third child at the age of forty-eight, and passed the climacteric at fifty. For twenty years she had been troubled with prolapse, but had become much worse in the past three years. She had never sought medical advice, her family ignoring her complaints until her presence became obnoxious to them on account of the offensive odors of her person. When she entered my consulting-room at the Boston City Hospital, I judged from the usually unmistakable odor that her case was one of uterine carcinoma; but examination revealed a condition well shown in this photograph.

The hernia was as large as a cocoanut, and consisted of the entire vagina and uterus and part of the bladder. There were several erosions and ulcerations, emitting a foul, purulent discharge. The vaginal wall was thickened. The uterus measured only a little over three inches in depth and was not therefore sufficiently heavy to have dragged down the vagina, but rather was dragged down by the gradually prolapsing vaginal walls. The patient for some time had been unable to empty her bladder, but passed urine frequently and in small quantities. Examination showed the urine to be slightly alkaline, specific gravity 1010, and to contain hyaline and finely-granular casts. The hernia was easily reduced; but a well-marked cystocele still protruded. Treatment consisted of rest in bed, glycerite of tannin tampons, and such general measures as the enfeebled condition of the patient demanded. In two weeks the ulcerations were healing rapidly, and in three weeks Mrs. T. was allowed to sit up most of the time. The mental condition, however, was unsatisfactory, and several attacks of unconsciousness and great general prostration (due in part to chronic diarrhœa) presaged an early lethal issue; there was therefore no indication for further local treatment, other than the continued use of a retaining tampon.

Pessaries of many kinds have been devised for the treatment of prolapsus, and some of them are of value in suitable cases; but experience has taught me that the safe and effective use of a pessary demands the exercise of a greater degree of care and intelligence on the part of the patient than is to be found in the majority of those suffering with the affection under consideration. Indeed, my rule is never to use a pessary in any patient until her docility has been thoroughly tested, preferring, if no other measure is available, to do no good rather than to accomplish temporary good at the risk of subsequent harm. It is well known, but not always remembered, that, if a pessary is efficient in retaining the parts, subsequent senile atrophic changes will often so narrow the vagina that the instrument is imprisoned and may cause serious ulcerations before the patient, by subjective evidences, is aware of it. Such cases are occasionally seen, in which the pessary has to be broken up before it can be removed. Within a year I have seen a case of cervical epithelioma undoubtedly caused by a long-worn and neglected pessary. This instrument should be used, therefore, only when it can be watched, the patient returning at stated intervals for the removal and cleansing of the pessary and for the inspection of the parts. Sometimes a patient can remove, cleanse, and replace her own instrument: in such cases the physician's attendance may be less frequent.

With those forms of pessary consisting of a cup supported by a stem and kept in place by external bands and belts I have had no experience, believing their use to be attended with too much annoyance and irritation about the external genitals and perinæum. When the prolapse is not extreme, I have often found the inflated, soft-rubber, doughnut-shaped pessary to be effective and safe. It will not, of course, raise the uterus to its proper place; but with care it will keep the parts within the introitus, and serve as a palliative measure when the various surgical procedures are contraindicated.

Mrs. C., aged seventy-six, multiparous, had probably suffered with a gradually-increasing prolapse for many years, but had borne her affliction in silence,

and it was only in the latter months of her life that the protrusion was discovered by her nurse. It was found that the uterus had undergone senile atrophy, and in the recumbent position was still within the introitus; but the vagina was prolapsed, and there was also a considerable prolapse of the urethra. Only palliative treatment was indicated, and this was successfully accomplished, after several trials, by the use of the inflated, soft-rubber pessary, by the help of which the parts were retained, and the patient enabled to go down stairs and go out driving. The prolapsed urethra retracted under the use of astringents, and gave no further trouble.

The opinion is held by many that the surgical treatment of genital hernia in the aged is unwise and unwarrantable, and the various objections given are, — that it is often unsuccessful; that, even if successful at first, the prolapse will recur; that it is not always safe to operate; that it is not worth while. Excluding from consideration the Alexander-Adams operation of shortening the round ligaments, and the operations for the removal of the uterus, I am unprepared to believe that the usual surgical methods are attended with more danger in the aged, if the patient is in suitable condition, than in those less advanced in years. Organic disease of vital organs should of course be given due prognostic importance in either old or young in considering the advisability of operative treatment; but age alone I do not recognize as a contraindication. Nor has experience taught me that primary and lasting success is less frequently attained in the aged than in the young: in fact, if intelligently performed, the restoration of prolapsed parts in those who have passed the child-bearing period and who have for whatever reason discontinued marital relations should be attended with better chances of lasting benefit than in younger women; not only because in the former senile changes diminish the possibility of subsequent prolapse, but also because the celibate condition warrants an almost complete closure of the vagina.

Whether or not operative treatment is worth while, the patient will often decide; but I never hesitate to advise a woman suffering with this infirmity, but otherwise in good health, to give up two or three months or less to radical treatment with a good prospect of entire relief, rather than to subject herself during the remainder of her life to the never-ending annoyance, inconvenience, and sometimes danger, of treatment with pessaries, which may be only partially successful.

Mrs. D., multipara, sixty years of age, for ten years a widow, came from another State to seek relief from prolapse of the uterus and vagina, which began to protrude twenty years before and for ten years had been outside the genital fissure. She complained of pain in the head and back; was unable to walk, stand, or sit without pain and discomfort in the prolapsed parts, and was comfortable only when lying down. Her general condition was fairly good; but her nervous system was in a measure unstrung by discomfort and pain. Defecation was always difficult: urination was frequent and sometimes painful on account of the prolapse of the bladder.

Physical Examination: Perinæum torn to sphincter, perineal body gone; vagina subinvoluted, thickened, and entirely prolapsed; uterus external to the vulva, enlarged, the cavity measuring four and a half inches; the cervix and vagina were the seat of many abrasions and ulcerations.

Treatment: The uterus and vagina were replaced and retained with tampons, the patient remaining in bed; a ten per cent. solution of nitrate of silver and a twelve and a half per cent. solution of tannin in glycerine were used to heal the abrasions. In less than three weeks the size of the uterus was reduced to three and a half inches in depth, the diminution of one inch being doubtless due in great measure to a retraction of the cervix. There being no apparent contraindication, the patient was then etherized, a large elliptical piece removed from the whole length of the thickened anterior vaginal wall, and the wound closed with sixteen sutures: a moderate venous oozing was controlled with hot water. Ten days later the parts were exposed and the stitches removed: the lower angle had failed to unite well; but two weeks later, when the patient was again etherized for posterior colporrhaphy, it was noticed that there had been no prolapse of the as yet unsupported anterior wall. The denudation for the second operation was carried well up the posterior and lateral walls of the vagina, and the wound closed with seven silver sutures, thereby narrowing the vagina and building up a large perineal body. During the convalescence the patient had considerable nervous disturbance with hallucinations, and several times she got out of bed in the momentary absences of the nurse; but on the removal of the stitches on the thirteenth day it was found that there was good union except externally, that is, at the base of the perineal triangle.

Ten weeks later Mrs. D. presented herself at my office, happy in entire relief. Examination showed a firm perineal body, the vagina would admit only the index finger, and the uterus was high in the pelvis: not wishing to distend the parts with a speculum, I did not measure the depth of the uterine cavity. The patient then returned to her distant home, and I have no proof that the result obtained was permanent; but apart from the probability that I should have heard from the case had the prolapse returned, it seems to me hardly possible with the vagina narrowed to the size of the index finger, the uterus diminished in size and weight and under favorable conditions for undergoing senile atrophy, that the parts could again descend to their previous position.

Mrs. R. C., a widow, sixty-five years of age, had borne six children, the youngest being thirty-two years old. She was a sober, industrious housewife, and her health had always been good until about a year before I saw her: at that time she was somewhat debilitated and began to suffer with "falling of the womb." At the time of consulting me she declared she was in perfect general health, and wished only to be relieved of the local trouble, which alone prevented her from performing her usual household duties.

Examination disclosed a complete prolapse of the anterior vaginal wall, which was thickened and whitened from attrition and exposure: the cervix protruded from the vulvar cleft, and the perinæum was torn; but there was no marked protrusion of the posterior vaginal wall. The uterus was not enlarged. The patient readily acceded to operative treatment; she was therefore kept in bed for a week and the parts retained with astringent tampons. It was at first proposed to remove a portion of the anterior wall before

closing the perinæum; but, as the uterus was not heavy, it was finally decided to make a more extensive denudation of the posterior wall and practically close the vagina, in the belief that in this way efficient support would be given to the anterior wall and subsequent prolapse prevented. The denudation was therefore carried well up on the sides of the vagina and to Douglas's cul-de-sac posteriorly: the wound was closed with silver sutures and dressed with iodoform by insufflation. The vagina would not admit the index finger.

The patient was comfortable after the operation, having scarcely any pain or constitutional disturbance: the temperature was normal on the third day. The next day, however, there was pain in the right labium, and a small abscess formed: this was opened externally and in no way interfered with the success of the operation. The stitches were removed on the ninth day, and two weeks later the patient was allowed to sit up and begin to walk about. Examination showed that perfect union had taken place and that the vagina would admit only a large-sized lead pencil. The general condition was excellent, and the patient returned to her family in just a month from the time of beginning treatment.

About five months later Mrs. C. returned for inspection of the parts: she was in perfect health, the vagina would admit only the index finger, there was no protrusion, the uterus was high in the pelvis and undergoing senile atrophy. Six months after this visit the patient again returned at my request. During this time she had performed her usual duties and had remained in good health: there had been no change in the local condition, the uterus still remaining high and the vagina narrow. It seemed to me, therefore, that her relief would be permanent.

The following case is reported not as a surgical success, but for its intrinsic ætiological interest and as an illustration of what is perhaps the best method of dealing with such cases under similar circumstances:

E. M., fifty-two years of age, single and nulliparous, a retired serving-woman, had passed the menopause ten years previously, at the age of forty-two. She had always been well and strong, but for the past twenty years had noticed a hard lump above the pubes and to the right: this, however, gave her no trouble, and she now sought relief from "falling of the womb."

It was found on examination that the vagina was entirely inverted and protruding from the *rima pudendi*: the uterus measured four and a half inches in depth and also protruded as far as the length of the vagina would allow. The pelvic brim was occupied by a hard, non-fluctuating tumor as large as a cocoanut, which was evidently a sub-serous, fibroid enlargement of the fundus uteri. Various pessaries had been tried to retain the parts within the vulva; but they either failed of their purpose or caused ulcerations necessitating their removal; the future treatment of the case therefore caused me serious consideration. Removal of the uterus seemed to afford the only sure hope of curing the prolapse; still as the tumor gave rise to no symptoms other than those caused by the hernia, so serious an operation was to my mind unwarrantable. On the other hand, with such a heavy mass pressing from above, narrowing the vagina, seemed an almost futile procedure. In the hope, however, that with advancing years the uterine tumor would diminish in size, I determined to perform the latter operation, and afford at least temporary relief.

After preliminary treatment with rest in bed and astringent tampons, the vagina was narrowed by colporrhaphy posterior, and three weeks later the patient was allowed to be on her feet again. Examination a week afterwards showed firm union to have taken place, the vagina would barely admit the index finger, the uterus was high and the cervix only just within reach.

The patient was not seen again until two months afterwards, now three weeks ago. It was then found there was some dilatation of the ostium vaginæ and a slight protrusion of the vaginal walls. The future issue of the case is doubtful; but, if the patient continues under my care, I shall endeavor to keep the parts within the vulva with a soft-rubber pressary, or with a cotton wad and T-bandage. And if this object can be successfully accomplished, senile atrophic changes in the tumor may ultimately so far reduce the weight of the uterus that a hard-rubber pessary can be worn.

THE FUNCTIONS OF THE THYROID GLAND.[1]

BY JAMES YOUNG SIMPSON, M.D., OF ORANGE, N. J.

THE functions of the thyroid gland have for many years been a subject of much interest to the medical profession. Our opinions have almost all been based on theories and conjectures until the last few years, when our knowledge has reached a much more definite status by the conclusions reached by experimenters, and students of this subject.

These conclusions are that the thyroid is a true gland, and that it holds a position of the most vital importance to the proper performance of our functions. For the further elucidation of this subject, we are indebted to the medical and surgical profession chiefly of England, Switzerland, Germany, and Italy, while America has furnished us with very little information.

The thyroid gland is a bi-lobed, dark-red, and vascular organ, enclosed in a thin, firm, fibrous capsule, from which numerous prolongations are given off to form a network on the interior. The meshes of the network contain a few elastic fibres, but contain chiefly vesicles, which form the body of the gland. These vesicles are minute, ovoid, spherical, or flattened bodies, and consist of a homogeneous, connective-tissue, basement membrane, lined with a layer of columnar or cubical epithelial cells, the whole enclosing a yellowish, transparent fluid. The cells contain nuclei, sometimes nucleoli, and have a tendency to undergo colloid degeneration, becoming swollen, and then rupturing, empty their contents into the cavity of the vesicle.

Granules, cells, and, according to Baber, large numbers of colored and colorless blood-corpuscles, are to be found in the interior of the vesicles. The colored cells are in a state of partial disintegration, and are supposed by some pathologists to be red blood-corpuscles destroyed by the natural function of the thyroid gland. The gland is very richly supplied with blood-vessels, and its lymphatics form huge lacunar spaces just outside of the margins of the alveoli, and these lacunæ probably serve to absorb the mucinoid substance found in gland, and then to carry it into the general system. Although having no duct, there

[1] Read before the Orange Mountain Medical Society, November, 1886.

seems to be sufficient reason for believing that the thyroid is truly glandular in its nature. In studying the physiological functions of this organ, we must consider, firstly, what significant symptoms are produced by diseases in which it is involved; and secondly, what effect upon the system does the entire or partial removal of this body produce either from necessity in human beings, or for experiment in animals. The thyroid is involved chiefly in three diseases; namely, myxœdema, cretinism, and exophthalmic goitre, the first being attended with atrophy, and the other two with hypertrophy; and it is to these diseases that we must turn to ascertain the symptoms produced by an interference with the functions of this body by pathological changes. Myxœdema was first described by Sir William Gull, although he spoke of it as a cretinoid state, the present name being given to it later. Ord afterward described the disease more fully, and has received from some quarters the credit due to Gull for having first called our attention to this condition. In every case of myxœdema, we find decided atrophy of the thyroid body — a condition variously described by authors as due to either disease of the trophic centres of the medulla oblongata, primary affection of the gland itself, or compression by the mucin deposited. The patient presents an appearance which is very striking. The face has a puffy, pallid, œdematous appearance; the lips and wings of the nose are protuberant and much thickened; the abdomen becomes prominent, the hands are flattened and swollen, and the skin is rough and dry. The apparently œdematous portions of the body do not pit on pressure, but are firm to the touch. Later in the disease, the expression of the face is heavy and unintelligent; the speech grows slow, uncertain, and hesitating; the gait appears clumsy and unsteady; the respirations and cardiac contractions are found to be depressed; the blood assumes a thin, watery condition; and the mind loses its activity and strength, until finally the victim of this disease is idiotic. There is no change in the kidneys, although, in the last stages of myxœdema, the urine is increased in quantity and contains albumen.

A few autopsies on these cases have revealed the presence of an increased amount of connective tissue in all of the organs, accompanied by the deposit of a thick, transparent, and slimy substance, similar to mucin. This mucinoid material may destroy the parenchyma of the organs involved by the pressure its presence produces. The disease is apparently a trophic neurosis, due to a disturbance of the central nervous system, accompanied by atrophy of the thyroid gland. We will next turn to cretinism, which is a peculiar condition, marked by deformity, idiocy, and goitre. It is found to effect people living in valleys of the Alps, the Pyrenees, and the Himalayas, and although many investigators have ascribed miasma and locality as its cause, the fact remains that the thyroid is involved in most of the cases, and, therefore, cannot be normally carrying on its functions. A Cretin is usually very short in stature; has a large, peculiarly flattened head; vacant, unintelligent countenance; thick lips, flat nose, large tongue, red, watery, and often crossed eyes; and a cadaverous, rough, dry skin. Idiocy of the lowest order is usually their condition.

The symptoms of exophthalmic goitre are well known to us, and we may divide them into three groups, consisting of bronchocele, protrusion of the eyes, and functional heart disease. Anæmia, chlorosis, or any factor which may depress the vitality may be the apparent cause of this disease. The fact that the exophthalmia disappears after death, and may be reduced by pressure during life, makes it probable that the cause is due to the intra-orbital bloodvessels becoming dilated, and not to the presence of an abnormal amount of adipose tissue at the back of the orbit. In most cases of this disorder, we find the cardiac contractions increased in frequency, and associated with a very distinct murmur, but in other cases the action of the heart is less frequent than normal. In the latter class, we very frequently find decided mental impairment; delirium, and epileptiform convulsions being often present. All of the symptoms appear to be due to an interference with the central nervous system, and although some writers have located this neuropathic condition at the cervical portion of the cord, or in the medulla, we have no definite proof that this is correct. It has been necessary for me to pass over these three diseases in a hurried manner, but I hope it is apparent to all of you that they are due to a disturbance of the central nervous system, and that interference with the functional activity of the thyroid gland is an important pathological factor.

To Kocher, of Berne, Switzerland, we are indebted for a very complete report of the symptoms following partial and complete removal of the thyroid gland. Having performed thyroidectomy on one hundred and one patients, his mind was first directed to the results following the operation by the appearance of one of his cases a few months afterward, when called in consultation with another physician. This case having disappeared from his notice for a number of months after the complete healing of the wound, he was surprised to find, when he again had an opportunity to examine the patient, that symptoms of a peculiarly striking nature were present. These symptoms, when described, we will all recognize as being similar to those of myxœdema. Desiring to investigate the subject, Kocher communicated with all his cases possible, and succeeded in personally seeing thirty-four of them, and obtaining letters from six.

From twenty-four of these patients he had removed the entire thyroid body, and from the remaining sixteen had removed only one-half. The latter were all in good health, but only six of the former were well, and three of these had present a supernumerary gland, which seemed to replace the thyroid. The remaining eighteen were all suffering from the same train of symptoms, differing only according to the time of removal of the gland. These symptoms clearly indicated progressive disease. First was noticed heaviness of the limbs, inability to endure fatigue, mental inactivity, dryness of skin, loss of hair; swelling of face, hands, and feet; anæmia, and finally, decided mental failure. Kocher applied to this condition the name of Cachexia Strumapriva, meaning Struma-goitre, and fully described it, without knowing of the symptoms ascribed to myxœdema by the English investigators, especially by F. Simon.

A year before Kocher's report, Reverdin, of Geneva, claimed that feebleness, anæmia, pallor, and swelling of the face and hands, followed complete thyroidectomy, but never placed his views before the profession with the same force that we find attending the statements of Kocher.

Wölfler has collected histories of sixty-eight cases of thyroidectomy performed by Billroth, from all of

whom the entire organ was removed, but arrives at very different conclusions from Kocher. He was unable to find any of the characteristic symptoms described, and claimed that complete removal was no more dangerous than partial.

Bardeleben contended while discussing Kocher's paper that the cachexia strumapriva of the Swiss surgeon was due to the disease itself, and the locality of the homes of the patients, and consequently this condition would have developed even had the gland been allowed to remain.

We have an assertion from Rankin which is very important in considering the cause of, or result from bronchocele, for he reports that of two thousand cases he had seen in India, not a single case of anæmia was he able to find among them. Experimental thyroidectomy has thrown much light on this subject. Cats and dogs, from which Schiff removed the entire thyroid body all developed a dull, heavy manner, with itching, paræsthesia, tremors, paralysis, and arterial dilatation. Inside of twenty-five days death had occurred in every case, although the wounds healed kindly in a few days. Horsley, of England, performed his experiment on monkeys and has given us a most accurate and complete account of the results obtained. The wounds healed completely in about three days, but at the end of about five a well-marked fibrillation was present, affecting chiefly the intrinsic muscles of the hands, jaws, and feet, this condition being followed by constant tremor, then by paroxysms, afterward by convulsions, and finally the fibrillation returned and death ensued. A few days after the operation the monkeys became languid and feeble in their movements, puffy around the eyelids and abdomen, and showed a marked lowering of temperature, pallor of skin, and leucocytosis, followed by oligæmia. Sometimes a partial hemiplegia was noticed, and although the motor centres appeared much involved, the sensation was very little impaired until near the end. The animals all died in a comatose condition in from five to seven months after the operation, and post-mortem examinations revealed hypertrophy of the fibrous elements of the connective tissue; mucinoid transformation of the ground substance as evinced by the presence of a shining, sticky substance; and an atrophic condition of the adipose tissue. These changes were associated with hypertrophy of the salivary glands, and instead of the excretion of saliva the glands were found to be pouring out mucin. The mucous membranes were much swollen and covered with an abnormal quantity of mucus. Marked distension of the meshes of the pia mater was found, and the central nervous system was decidedly anæmic and atrophic.

Horseley maintained that tremor in these cases was probably of central origin, from the fact that the pathological changes were found there and none apparently in the nerves; also that division of the nerves supplying the affected muscles had no result, that inhalation of ether increased them, and that reflex action caused them to disappear. Examination of the blood demonstrated that it had increased in its number of white corpuscles, decreased in its proportion of red corpuscles, and lost some of its power to coagulate. Lanquirico and Canalis, of Italy, extirpated the thyroid body of twelve dogs and obtained results corroboratory of Schiff. All the animals died inside of sixteen days. Anæmia and œdema of the brain was found at the autopsy, and but slight changes in the blood. Zesas experimented on dogs and cats, and all died within a few weeks. Marked cerebral anæmia was present, and to this he attributed the dull, weak, and progressive marasmic condition attending his cases. A few cases operated on by Wagner have still further confirmed the results of Schiff, for although the animals died in a few days, and probably from the operation, the nervous symptoms noted, indicated a disturbance of the central ganglia. Kaufmann has attempted to contradict the conclusions of these experiments, by operating on three dogs and exhibiting the results. One died in five weeks from distemper, and the other two were living nine months after the operation, but according to Zesas were very emaciated. However, Kaufmann, Wölfler, and Tauber support Bardeleben in opposition to Kocher. It is also asserted that the last named surgeon's patients were quite young, and that he would have had better success in older patients whose constitutions were more matured. This is somewhat disproven from the fact that only nine of Kocher's patients were under twenty. Having described the symptoms accompanying disease of this organ and the conditions following thyroidectomy, let us now turn to a consideration of the deductions made by these eminent experimenters and physiologists. Schiff, Lanquirico, and Canalis concluded that the thyroid gland exercises a great influence over the nutrition of the central nervous system; Zesas holds that it has a certain hæmatogenous function similar to that of the spleen, and is also an important regulator of the intracranial circulation; and Horseley believes its hæmatogenous function is the formation of red blood-corpuscles and that it also excretes mucin. Liebermeister and Guyon support Zesas in his conclusions in relation to the effect this gland produces on the blood-supply of the brain. This theory is also upheld by Simon, who acknowledges the probable intimate relation between the thyroid and the nutrition of the nervous system.

Lushka has advanced the idea of it being a mechanical bolster to keep pressure from the important structure of the neck, a theory, however, which has met with but little favor. English authorities seem to be well agreed that myxœdema, cretinism, and cachexia strumapriva are the same disease somewhat modified in each form and described under a different name. In view of the fact that in all three of these diseases, in exophthalmic goitre, and in the condition following thyroidectomy, nervous symptoms are so constantly and prominently present I believe the thyroid gland bears a relation of very high functional importance to the central nervous system, and also that it excretes into the interior of its vesicles a mucinoid material which is taken up by the lymphatics; a belief which is based on the presence of this substance in the acini of the gland and throughout the body in myxœdema, cachexia strumapriva, and the animals used for experiment. The theory that it is a regulator of the intra-cranial circulation is based on the anæmic appearance of the brains of patients and animals examined, and also on the decided mental failure attending the cases; while the claim that it has a hæmatogenous function which gives it the power of producing red blood-corpuscles has foundation only in the degenerated colored cells found in the vesicle, and the decreased number present in the blood of the diseased patients and vivisected animals. Much more

accurate and positive information will be needed before we can accept either of these functions as assured. The idea of it acting as a mechanical bolster is certainly very fanciful and somewhat disproved when we consider that pressure on the deeper structures of the neck is usually the cause for removal of the gland. That the thyroid has any connection with the spleen is confuted by experiments on rabbits by Tizzoni. He clearly demonstrated that splenectomy caused no changes of any kind in this organ. It appears well, therefore, in view of the present information obtainable in relation to this subject that we should never undertake the complete removal of this important organ unless it is absolutely necessary. In closing, I desire to express my regret at being unable to do more justice to a subject of such importance, but realize that I have already sufficiently encroached on your time.

Clinical Memorandum.

A REDUCING SUBSTANCE IN URINE RESEMBLING GLUCOSE.

BY T. BARTON BRUNE, M.D., OF BALTIMORE, MD.

A FEW days ago a specimen of urine was sent to the writer, the analysis of which revealed the presence of a substance likely to be of importance to Life Insurance Companies and of considerable interest to individuals applying for insurance. On the 13th of this month, the agent in this city, of one of the prominent New York Life Insurance companies sent me a sample of urine and the following account of it. It was passed by a young man of good physique, who had in the last three years gained fifteen pounds in weight and three inches in abdominal girth and also was in apparently perfect health, but had been repeatedly turned down, as a bad risk, by prominent medical examiners of other first-class companies because of the presence of glucose in his urine. As he had recently been examined by the medical staff of the agent's company and some doubt had been raised regarding the presence of glucose in his urine and as he wished a large insurance, the agent requested me to analyze the accompanying sample and communicate to him the result of the analysis. The analysis, made December 13, 14 and 15, was as follows:

ANALYSIS OF THE URINE.

Physical characteristics. Urine sparklingly clear, light amber in color, urinous smell, acid reaction, specific gravity 1022; amount for twenty-four hours said to be 32 ounces. No sediment when received. Applicant on ordinary mixed diet, having eaten nothing unusual and taken no medicine.

Normal Constituents. Indican and other normal ingredients of urine present in normal quantities, as determined approximatively. No bile pigment as determined by sulphuric acid and nitric acid containing little nitrous acid. No albumen.

Upon standing several hours (fourteen) a very slight, flocculent, whitish sediment appeared, and the supernatant fluid began to be discolored, a reddish yellow, later a brownish-red, from its surface down.

Heller's or Moore's Test. Upon the addition of a solution of *sodic hydrate* (1-3) the earthy phosphates were precipitated in considerable quantity and the supernatant fluid became a port wine red, later (after a few hours) almost black. This effect was hastened by *boiling*. *Nitric acid* in small quantity rather heightened the color, but in excess almost decolorized it without evolving any caramel odor. The sodic hydrate was proven free from lead salts, and the urine free from hydrogen sulphide. Probably from this reaction a considerable quantity of grape sugar was supposed by some examiners to have been present.

Bostger's Test. Upon the addition of *subnitrate* of *bismuth* and solution of *sodic hydrate* in the cold, a reaction took place in the supernatant fluid similar to that above, but the subnitrate was not abnormally discolored even upon *boiling*, becoming simply a very light brown.

Roberts's Modification of Fehling's Test. Upon boiling 4-5 c.c. of Fehling's Test Fluid, as recommended by Roberts, and adding 1-2 c.c. urine there first appeared a dark greenish discoloration rapidly followed by separation of a greenish-white sediment from a dark brown supernatant fluid. On standing an hour its sediment resolved itself into a greenish-white layer superimposed upon a mixed red and orange layer, a reaction resembling that of sugar.

Johnson's Picric Acid Test. Ten minims of *picric acid* solution gave, according to Johnson's method, a reaction similar to that produced by one and a half grains of glucose, and twenty minims a reaction such as would be caused by two grains per ounce of urine. In both cases, however, the discoloration ensued before as well as after boiling, and the resulting color was more brown and less red than that produced by glucose.

Fehling's Test. With *Fehling's* test a very unsatisfactory reaction ensued, for while a slight amount of cuprous oxide was precipitated, instead of decoloration of the supernatant fluid there resulted a deep brown discoloration similar to that produced by too long boiling of the fluid in Roberts's test.

Fermentation gave no result even after thirty-six hours.

Ultzmann's Saccharimeter. The *polariscope* showed upon repeated trials a lœvo-rotation of 0.2°, a rotation, although the opposite of that caused by glucose, too slight to be of value.

Thymol and *sulphuric acid* gave a light violet color.

Upon the addition of *silver nitrate*, a grayish-white precipitate resulted, which quickly blackened upon agitation.

Ferric chloride gave a faint green precipitation.

Nitric acid gave a light yellow instead of violet purple zone between its fluids.

Boiling gave a reddish purple clear fluid.

Galippe's Test. Picric acid gave the faintest possible white-cloudiness, which cleared upon boiling, and no abnormal darkening of the mixture.

The *microscope* revealed that the sediment consisted of mucus with urates and some irregular crystals, and a few pigmented granules.

CONCLUSION.

The presence of glucose indicated (shall I say to the non-specialists?) by the sodic-hydrate, copper, and, perhaps, picric acid and bismuth-subnitrate tests, is absolutely negatived by the polariscope, the fermentation, silver-nitrate and ferric-chloride tests, and a proper interpretation of the other tests. Clearly, the question as to the presence of glucose is answered in

the negative. As to the next question, What is the abnormal substance giving these reactions? I cannot answer without further analysis, but hope to supplement this by an account of its discovery. Whatever it is, it would seem to be in small quantity, and to have little if any pathological significance. The brownish discoloration of the urine from above downwards, and its reaction with sodic hydrate and its copper salts, would indicate a substance discovered in urine by Baedeker in 1861 and called "alkapton." This body is, however, probably a composite one, and its further reaction with ferric chloride and silver nitrate would point towards pyrocatechol or proto-cateclinic acid, (both of exceedingly rare occurrence in its human urine) as the possible cause of its behavior of the urine. The analysis, however, is not complete. Although such is the case, two important lessons may be drawn from this analysis: — The one is that the copper and sodic hydrate tests, as generally used, are not sufficient *positive* tests for glucose, but should be supplemented by the fermentation, subnitrate of bismuth and polariscope tests, or, in doubtful cases, by all three; the other is that medical examiners should not lightly tell applicants for insurance that they are suffering from serious illness. For this applicant was very much alarmed by a very prominent examiner in another city telling him he was in the last stages of diabetes and absolutely refusing to recommend him for insurance.

Reports of Societies.

QUARTERLY MEETING OF THE RHODE ISLAND MEDICAL SOCIETY.

A QUARTERLY meeting of the Rhode Island Medical Society was held in Providence, December 16, 1886, the President, DR. HORACE G. MILLER, in the chair.

Delegates to medical societies for the ensuing year were appointed as follows: Maine Medical Association, F. B. Fuller, C. V. Chapin; New Hampshire Medical Society, Eugene Kingman, G. T. Swarts; Vermont Medical Society, C. H. Leonard, L. S. Hill; Massachusetts Medical Society, J. H. Eldridge, H. R. Storer; Connecticut Medical Society, C. H. Fisher, F. T. Rogers; New York State Medical Society, J. W. Mitchell, J. W. C. Ely; New York State Medical Association, J. H. Morgan, Charles O'Leary; New Jersey Medical Society, F. H. Rankin, A. J. Browning.

DR. W. R. WHITE reported

A CASE OF INTESTINAL OBSTRUCTION IN AN INFANT CAUSED BY THE INGESTION OF WOOL.

The patient, a girl aged twelve months, had had no evacuation of the bowels for two and a half days, and during the last twenty-four hours had been very restless and uncomfortable, refusing to nurse, and evincing abdominal pain. To relieve her, the mother had given no medicine, but had tried enemata of warm water and molasses without avail. The last enema was followed by a severe convulsion of short duration. Dr. White gave two grains each of calomel and sugar. One dose was effectual, the child having within ten hours four copious and painless dejections, composed of normal fæcal matter, with which was mixed masses of wool-fibres to the amount of two handfuls. The mother recognized the nature of the foreign substance by numerous pink and blue fibres, which she then remembered to have seen the baby picking from the fleece of a soft woolen blanket on its crib.

DR. W. E. ANTHONY recalled a similar accident in the case of a child three years of age, who had no movement of the bowels for three days, and had received two ineffectual doses of castor oil, causing great pain. In attempting to introduce a syringe, he met an obstruction immediately above the sphincter ani, and with the only instrument available, a button-hook, he removed twenty-eight squash-seeds, which were found impacted in a solid mass.

DR. F. C. CLARK advised small doses of calomel for these intestinal obstructions of children. One or two grains frequently repeated yields more satisfactory results than the use of enemata.

DR. H. CANFIELD read a paper on

HEALTH RESORTS AT THE SOUTH, WITH REMARKS ON THE GENERAL SUBJECT OF CLIMATOLOGY.

The ideal locality for any class of invalids during the winter months does not exist, nor will any one locality ever be found fulfiling all requirements. Different places offer certain peculiar advantages from which the physician may choose for every individual invalid.

The sand region of the Carolinas is characterized by a climate moderately warm, with a marked diurnal variation, a moderately low relative humidity, again with a marked diurnal variation; an ordinary amount of sunshine, great purity of air, good provision for living, monotonous scenery, poor means of recreation, but easy accessibility. They answer as good half-way stations for the sick invalid in going South in the fall and returning in the spring, while the semi-invalid may prefer them for the whole winter.

The mountain region of the Carolinas possesses a slightly colder climate, with less diurnal variation, a relative humidity about equal to that of the sand belt, a greater amount of sunshine, greater purity and invigoration of air, fair provisions for living, the finest scenery, good means of recreation, and fair accessibility. This is the climate for those who do not object to a moderate degree of cold, and is probably the best for creating a healthful reaction in the diseased system.

The eastern coast of Florida is warm and moist, subject to sudden changes, both in temperature and humidity, has a fair amount of sunshine, good, and, for Florida, very bracing air, the best of provision for living, fair scenery, numerous resources for recreation, and easy accessibility. The semi-invalid, the lover of good society, the aged, will find here a most delightful locality for passing the winter months. The lake region of Florida is slightly warmer, much drier, has bright sunshine, a pure, easy-living air, fair provision for living, for Florida, varied scenery, fair means of recreation, and easy accessibility. The Gulf Coast is still warmer, with a greater relative humidity than the lake region, but less than that of the Eastern coast, plenty of sunshine, an easy-living, but poor recuperative air, no provision for living, fair scenery, numerous objects of diversion, and good accessibility.

For sicker invalids, the lake region is by far the best of all Florida; those who can "rough it" should not stop short of the Gulf Coast.

DR. CHARLES V. CHAPIN read a paper on

DISINFECTION AND DISINFECTANTS.

Steam at a pressure of twenty-five pounds, at which its temperature is 240° F., destroys the most resistant spore almost immediately. At lower temperatures it requires longer to act. Boiling water will kill microbes without spores almost instantly, and boiling for half an hour will destroy all disease-poisons.

Chloride of lime, or more properly, bleaching-powder, is best used in solution. Its value depends upon the chlorine it contains. The standard solution recommended by the Committee on Disinfectants of the American Public Health Association is four ounces to the gallon. For this purpose, the bleaching-powder should contain twenty-five-per cent. available chlorine. Labarraque's solution is practically the same thing, being a solution of hypochlorite of soda, but the strength of the preparations on the market is very variable, some of it being worthless.

Mercuric chloride in the strength of 1–1000 destroys all spores within two hours, and it is an efficient antiseptic in the strength of 1–15000. The poisonous character of this salt interferes with its indiscriminate use. It should not be used in lead pipes or in a pan water-closet. The standard solution of the American Public Health Association is two ounces to the gallon. This for safety had best be colored, which may be done by the addition of one pound of sulphate of copper, another disinfectant of considerable value. Mercuric chloride coagulates albumen, and as disease germs are often contained in albuminous material, the action of the disinfectant is thus frequently interfered with.

Dry heat requires that the article to be disinfected should be for two hours exposed in an oven at 300° F., a temperature which injures woolens. Moreover, unless the articles are freely opened, the heat will not penetrate to their interior.

The fumes of burning sulphur, sulphurous acid gas, when present in one per cent. of volume, destroy in a few hours certain disease poisons, but does not, even in much larger proportion, kill the spore-producing microbes. This gas is easily generated, and, within certain limitations, is a valuable and almost indispensable disinfectant. Three pounds of sulphur should be burned for every 1000 feet of cubic air space of the room to be fumigated.

Carbolic acid, even in saturated solution, does not destroy spores, but in two per cent. solution it will in two hours kill microbes without spores. Thus it is seen that the vapor of carbolic acid can have no value whatever as a disinfectant.

The salts of zinc, the suphate and chloride, are not disinfectants at all, but are often useful as antiseptics or deodorizers. The same can be said of the sulphate of iron.

Hydrochloric acid is a valuable disinfectant in the strength of 1 to 50, and is a good antiseptic in the strength of 1 to 1700. It deserves to be used much more than it is at present.

In the present state of our knowledge, it is impossible to name a single disinfectant which can be given internally in sufficient quantity to kill the disease virus or even to suspend its activity without killing the patient. All we can attempt to do is to destroy or hinder the growth of disease poisons outside of the body. We can disinfect the room and the air it contains, the clothing and bedding, the drains, vaults and cesspools, and even food and drink, but we cannot disinfect the alimentary canal or the blood, neither can we put antiseptics into them with safety. The prevention of infection is better than disinfection. Isolate the patient; expose as few articles as possible to the contagion; remove filth and repair the drains rather than rely on the use of disinfectants and deodorants.

DR. GOLDSMITH, while admitting the utility of sulphurous acid gas in fumigating small rooms, pointed out the special value of chlorine in the case of hospital wards.

DR. GREENE inquired as to the disinfectant value of coal tar. He had used it successfully in case of foul soil-pipes.

DR. CHAPIN said that coal tar is a complex chemical substance, and some of its elements may have some power as disinfectants. Coal tar, like carbolic acid, has feeble disinfectant power, but is something of a deodorant. The best way to clean out pipes is to pour down a boiling solution of caustic potash, followed by free use of clear water.

DR. SWARTS asked whether there were any statistics of acknowledged value concerning the relative merit of the various disinfectants.

DR. CHAPIN replied that it is very difficult to get accurate facts about the value of special disinfectants. Health officers in most large cities use the sulphur fumes for fumigating.

DR. LEONARD called attention to *aqua ammonia* spray as a good measure, in addition to full ventilation, to free the room of sulphurous gas after fumigation, but the pungent fumes would still be troublesome to sensitive lungs for some hours.

DR. F. P. CAPRON reported two cases of

MASTOID DISEASE

which recovered.

DR. E. T. CASWELL exhibited a

DERMOID CYST OF THE OVARY,

which he removed from a woman fifty years of age. The patient made a good recovery after a protracted convalescence of six weeks, during which she suffered from obstinate vomiting requiring rectal alimentation.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

DECEMBER 13th, 1886.

The PRESIDENT, DR. F. W. DRAPER, in the chair.

VACCINATION COMPLICATED BY A TRIVIAL WOUND.

DR. J. B. AYER who reported the case had vaccinated on the arm, a healthy eight months' child with bovine matter. The following day, while crawling on the floor, he got a small wooden splinter in his leg just below the knee, which was soon removed.

On the eighth day vaccination had taken perfectly in both places with less than the ordinary amount of irritation and without eruption elsewhere upon the body.

The mother called attention to the leg, but there was nothing visible except a minute abrasion which did not appear to be inflamed. He was called, however, five days later and found phlegmonous inflammation about the abraded spot. In a few days it was

lanced, evacuating a large amount of pus, but no bit of retained splintered wood was found in the wound, as had been expected. Inflammation extended downward and a second abscess formed above the ankle. This was lanced and recovery followed at the end of a month.

This case showed that trifling local irritation could be the source of much trouble in the course of vaccinia, notwithstanding the fact that the child was healthy, and the vaccine matter excellent.

DR. H. I. BOWDITCH suggested that vaccination and the slight wound might be mere coincidences; and that the splinter could have had the same effect even if the child had not been vaccinated.

SUBCUTANEOUS ŒDEMA, OR ASCITES TREATED BY PROLONGED DRAINAGE THROUGH FINE CANULÆ.

DR. W. C. B. FIFIELD showed an instrument, the invention of Dr. Southey, of London, consisting of a fine trocar with canula, this last having evenly rounded projecting shoulders. There was also a fine rubber drainage tube. The trocar with a canula was thrust through the side of the tube and then obliquely through the skin, or directly into the abdominal cavity. Next the trocar was withdrawn, and lastly the projecting shoulder of the canula was pushed directly into the tube. A number of canulæ accompanied the trocar.

This he had used fourteen days ago in a case of cirrhosis of the liver, where the patient was unable to lie down because of œdema, the swelling of the scrotum in particular being such that the penis was lost to sight. These canulæ had been left in for days without causing inflammation. Some nine quarts of fluid had been evacuated with great relief to the patient and without wetting the bed, the fluid being carried off by the tube. Dr. Southey had used the same instrument in ascites, passing the trocar into the abdominal cavity and leaving in the canulæ. The only objection to this instrument seems to be that rubber, and especially foreign rubber, spoils in no long time. The ordinary tapping the skin with needles is objectionable, in that it wets the bed and clothing, causing irritation of the skin.

DR. FRANCIS MINOT said that he had seen a similar instrument used in the peritoneum for ascites in his wards of the Massachusetts General Hospital just before beginning his own service. He thought that the skin might be punctured in œdema more often than is done. A patient that he had seen in consultation had been drained from September until her death in May or June from punctures in the ankle and with great relief. Fluid ran off rapidly when she was sitting up, but generally not so well when in bed. Puncture gave complete relief to dyspnœa.

DR. FIFIELD said that tubes so small as in his instrument could not, he thought, be got in this country.

DR. C. M. GREEN read a paper on

THE TREATMENT OF PROLAPSE OF THE UTERUS AND VAGINA, ESPECIALLY IN THE AGED, WITH ILLUSTRATIVE CASES.[1]

DR. W. H. BAKER expressed himself as strongly in favor of operative treatment in proper cases. The operation gives permanent relief. He had performed it a great many times and had seen the displacement recur in one case only. He wished to emphasize as a reason for operating, the fact that many of these patients are careless. The same woman who at thirty or forty or fifty will take very good care of herself, will at sixty or seventy or eighty become neglectful, and this habit of neglect is a reason for not trusting to pessaries in advanced life. He showed a soft rubber ball which he had many years before removed from a woman who was supposed to have cancer; but who had really this ball cracked open, and filled with foul discharge, she having worn it for three years. It had been removed with difficulty, and simply illustrates what he had been saying. In speaking of muscular effort as a cause, he mentioned a woman who had caused this prolapse by lifting the end of a piano, and he had twice known a less severe effort to have a similar result.

It is true that in the poorer classes this prolapse is more often marked than among the wealthy, for the reason that it is more often neglected; but this neglect is in part at least, due to a difference in nerve tolerance. Women of the lower class appear at the dispensary and say that the womb is down. It annoys them because they have to support it with a napkin, but it causes no pain; while women of the educated class will suffer from the same lesions. In other words, the educated woman has less nerve tolerance than the uneducated, and we have no right to assume that there is not pain in the cultivated, because we may have seen the same condition borne without complaint by a dispensary patient. The higher the education, the less the nerve tolerance.

In regard to operation, it may be proper in the very aged to close the vagina to the size of the finger or less for the purpose of ensuring a permanent result, but we cannot do so in younger women. Yet we see women at thirty or forty with this prolapse, and in them the speaker prefers to make the narrowest part of the passage very high up. It may be made nearly as high as the cervix.

Dr. Baker also spoke of the different methods of operating. That of Emmet, in which but a narrow surface is denuded, depends for success upon the holding of all the stitches and we do not get so much strength as if more is cut away. He prefers to draw the walls together experimentally with hooks and to mark the place where the utmost amount of coaptation can be secured, allowing for swelling after the operation. If the entire thickness of the mucous membrane is cut away the adhesions will be firmer. In order to do this safely, the bladder must be pushed up out of the way. He uses silver sutures and leaves them in for two or three weeks.

DR. FIFIELD related two cases in which permanent good appeared to be done by electricity.

[1] See page 615 of the Journal.

— A writer in the *New York Medical Monthly* reports an operation of circumcision in a patient over ninety years of age, suffering from the effects of an elongated prepuce, which, as the author says, should have been removed just ninety years and ten days before it actually was. The somewhat belated operation was performed successfully without ether, cocaine being injected into the preputial fold, and the aged patient beguiled the time for his surgeon by telling stories throughout the operation. The healing was rapid, and the gentleman is now provided with a serviceable organ.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, DECEMBER 30, 1886.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES, UPHAM & COMPANY,
283 WASHINGTON STREET, BOSTON, MASS.

ANNUS MEDICUS, MDCCCLXXXVI.

WITH the closing number of another year it becomes the duty of the JOURNAL, in accordance with its custom in the past, to gather up a few of the threads of the medical history of the year.

The Pasteur movement has by no means ceased during the year. A Pasteur Institute was founded in New York early in January. Dr. Pasteur (as he is now, having been given the degree this year, *honoris causa*) received a grant from his government of a location for his hospital for thirty years, but on his objecting that this was too ephemeral a lease for the character of the buildings contemplated, it was extended to ninety-nine years. Among his sharpest critics have been Frisch, of Vienna, and Professor Colin, of the Veterinary School at Alfort, France. On the other hand, we learn from the statement of the President of the Local Government Board of England made to Parliament, August 26th, that the British Hydrophobia Commission, under Dr. Victor Horseley, appointed to investigate Pasteur's methods, though not ready to make a formal report, were substantially satisfied of the effectiveness of the treatment. The report made by Pasteur to the Academy in the fall was naturally the occasion of a sharp discussion. The details of his communication have already been laid before our readers. Up to October 31st he had inoculated 2,490 persons, of whom 1,700 were French. Out of the latter number ten had died. The mortality among the foreigners was much larger. Among wolf-bitten Russians, at any rate, his inoculations have evidently not been successful. According to the figures which we allow for the cases in which the biting dogs were not really rabid, and again for the cases in which even a bite from a rabid dog produces no hydrophobia, will be our confidence in the life-saving power of Pasteur's inoculations.

Our English brethren have been much exercised during the year over the subject of "direct representation" in the General Medical Council. This body, constituted by Parliament in 1858, has hitherto consisted solely of appointees of the Crown, and of the great licensing corporations. Its chief function has been the registering of medical practitioners. Last summer Parliament voted that the latter class of persons should be entitled to elect five out of the thirty members of Council, and, during the last two months, the ballot has been cast for three representatives from England, one from Scotland, and one from Ireland. From a total registration of 18,074, 13,381 votes were cast, showing the wide interest taken in the matter. Among the successful candidates was Mr. Wheelhouse, a Leeds surgeon, who has held important offices in the London College of Surgeons. Except in his case and that of Dr. Kidd of Dublin, the Irish representative, who is a member of the Council of the College of Surgeons, and an ex-president of that body, the "general practitioners," distinct from all licensing bodies, to whom it was the special aim of this act to permit representation on the Council, are considered to be well represented. The other members chosen are Dr. Glover, one of the editors of the *Lancet*, Sir Walter Foster, and Dr. Bruce of Scotland. Among those already in the Council are Sir Henry Ackand, Professor of Medicine at Oxford, President of the Board, Matthews Duncan, Richard Quain, and others more or less well known on this side of the water.

Medical education has had several windfalls during the year by legacy, though we regret to say that the medical institutions of New England have not been so fortunate as some others. The late William H. Vanderbilt left $500,000 to the College of Physicians and Surgeons in New York. This was supplemented by another fund of $250,000, contributed by three of his sons for a "Vanderbilt Clinic" in connection with that institution, and by a nearly equal sum from his daughter, Mrs. Sloane, for a maternity hospital. Thus the benefactions of the Vanderbilt family to this college of medicine have amounted to nearly $1,000,000. Mrs. Woerishoffer gave to the New York Academy of Medicine $25,000 in memory of her husband. By the death of Lady Wilson, the Royal College of Physicians of England gets about £200,000 from the estate of the late Sir Erasmus Wilson.

Among the prominent national society meetings for the year were the following: The Seventh Annual Meeting of the American Surgical Association was held in Washington, April 28th to May 1st. The Thirty-Seventh Annual Meeting of the American Medical Association was held at St. Louis, May 4th–7th. The Third Annual Meeting of the American Climatological Association was held in Philadelphia, May 10th and 11th. The Eighth Annual Meeting of the American Laryngological Association was held in Philadelphia, May 27th and 29th. The First Meeting of the New Association of American Physicians was held in Washington, June 17th and 18th. The American Otological Society held its Nineteenth Annual Meeting at New London, July 20th, which was followed, immediately, July 21st and 22d, by the Twenty-Second Annual Meeting of the American Ophthalmolog-

ical Society. The American Neurological Association held its Annual Meeting July 21st–23d at Long Branch, N. J. The Fifty-Fourth Annual Meeting of the British Medical Association was held at Brighton, August 10th–13th. The American Dermatological Association held its Tenth Annual Meeting at Greenwich, Conn., August 25th–27th. The American Gynæcological Society held its Eleventh Annual Meeting at Baltimore, September 21st–23d. The Fourteenth Annual Meeting of the American Public Health Association, with a conference of State and Provincial Boards of Health was held at Toronto, October 4th–7th. The American Academy of Medicine held its annual session at Pittsburgh, October 12th–13th.

The Assembly of German Physicians and Naturalists met at Berlin in September. The French Congress of Surgery met in Paris, from October 18th to October 24th, and discussed chiefly tetanus, nephrotomy and nephrectomy, orthopædic resections, and operative intervention in irreducible traumatic dislocations. The International Congress of Hygiene which met at the Hague in 1884, was appointed to meet this year in Vienna, but for some unexplained reason did not assemble, and the meeting is now announced for next year. The International Congress for Climatology and Hydrology met at Biarritz, October 1st.

A movement was originated by the American Surgical Association in the direction of the formation of a Congress of American Physicians and Surgeons, which should be a more representative body than any existing organization of the best work of the profession in this country. Committees were appointed from the various societies which were invited to join in this congress, namely, the American Surgical, Climatological, Laryngological, Neurological, Otological, Ophthalmological, Dermatological and Gynæcological Associations, and the Association of American Physicians. These committees met at Washington in September and, though there was a strong spirit manifested by most of the delegates towards preserving the absolute autonomy of each society in all matters concerning its meetings, it was voted to hold a conjoint meeting of the Societies in Washington every three years, beginning in September, 1889, such meeting to occupy two evening sessions, at one of which there should be an address and at the other a topic for discussion.

Meantime, what of the prospects for an *International* Medical Congress in this country in 1887? The death of the lamented Dr. Austin Flint left a vacancy in the presidency of the Congress which Dr. N. S. Davis, of Chicago, has been selected to fill. The Executive Committee have also filled up other vacancies in the general offices of the Congress and of the respective Sections, caused by the resignations of men who did not endorse the methods of the Congress. Those objectors have with scarcely an exception adhered to their resolution to stay out. For this reason, as well as in accordance with the "territorial policy" of the management, the cities of the Atlantic Coast will have but a small representation in the honors of the Congress. The principle of territorial representation has been carried to a considerable length, but has not yet had its perfect work. Texas and Oregon are fairly provided for, but Alaska, which in accordance with this principle of appointments, is entitled to nearly a third of the offices, has thus far been treated very shabbily. A few more Sections will have to be added to the eighteen already announced, if all our great country is to be adequately represented. We learn that Dr. Pancoast, of Philadelphia, has personally invited the Queen of England to be present. Should she come (and how can she do otherwise?) it will be a great time for the bird of freedom. It is proposed to ask Congress to furnish a little pap.

Among the general educational interests of the year which especially deserve mention in this connection, was the Heidelberg festival, held last summer in commemoration of the 500th anniversary of the foundation of that seat of learning. Our own younger university, Harvard, attained this year the completion of her first quarter millennium, and this occasion was celebrated at Cambridge with festivities whose recollection is not only fresh in our readers' minds to-day, but will remain equally distinct for many a year to come. Nor should we omit to add a word of the distinguished part borne by our own poet on that occasion, who had but just returned to us crowned with the highest academic honors of Oxford, Cambridge, and Edinburgh.

The epidemiology of the year is of interest. Fortunately, in this country, we have escaped any considerable infection by any of the devastating epidemic diseases. At the beginning of the year cholera was still lingering in Spain, causing considerable havoc in certain towns — in Alcante, Murcia and Granada. In February it sharply attacked Tarifa, the southernmost town of Spain, where, of a population of 3000, fifty were struck down in one day. From this time it gradually diminished in Spain. Passing over France, it took a general easterly course, being present through the summer in Italy, but without causing the same alarm that prevailed in the previous year, and towards autumn and early winter attacking Hungary, the southern Austrian provinces and the Turkish frontier. In Italy, cholera appeared at Brindisi in the middle of April, with only moderate severity.

A number of local epidemics occurred. Quarantine, or as it has become the fashion to call it since the Roman Sanitary Conference, "observation," was maintained by all Mediterranean ports against Italy. The reliance of that country on quarantine was shown to be weakening by a unanimous protest of the Chamber of Commerce of Venice against all quarantine restrictions, in which protest they were, for the first time, supported by some influential papers in Rome and other cities.

In Venice, during the spring, it was asserted, though denied by the authorities, that occasional cases of cholera had appeared, but an official bulletin was required by May to allay the growing uneasiness by

an exact statement of the number of cases. Regular bulletins appeared after that. With the occurrence of warmer weather at the end of May, the cases in Venice decidedly increased, there being eighty-five deaths in the last week of that month, and one hundred and twenty-one for the first week of June. Though the disease appeared with spasmodic virulence in scattered parts of the country, the provinces of Venetia and Brindisi continued to bear the brunt of it.

In September a number of cases of cholera appeared in Buda-Pesth, as well as at Trieste and several other towns of Istria. Early in October it was officially announced that the epidemic of cholera had ceased at Venice, though scattered cases were reported from other Italian towns, and a few at Rome. At Pesth the deaths were averaging six a day and were on the increase. In the latter part of October a case occurred in Vienna; Austrian and Turkish Croatia were then involved. An outbreak occurred among the garrison at Belgrade, where, between November 21st and 27th, there were fifty cases and ten deaths.

The history of cholera in Japan during the first half of the present year gave a total of 10,276 cases, with 7,803 deaths, about 75 per cent. of *reported* cases, at least. During the summer the mortality continued to be large in Yokohama and Tokio, as well as in Corea. The mortality in the latter island has been frightful. Early in the fall the deaths at Seoul, the capital of Corea, numbered 1000 per day, and there were no means of burying the bodies.

In South America, cholera has established itself since November, in the Province of Buenos Ayres of the Argentine Republic. Several towns report from twenty to thirty new cases daily, and the city of Buenos Ayres is reporting from thirty to forty cases daily, with a mortality of 60 to 70 per cent. The large Italian immigration is undoubtedly responsible for the introduction of the disease, which will probably be heard of next in Brazil.

The Local Government Board of England, which during the first of the year had laid a prohibition on the importation of rags from Spain, extended that prohibition, on April 1st, for four months, and the Board of Supervision also extended the prohibition in Scotland till August 26th. No further extension of this restriction was made, the cholera having ceased in Spain, but on July 3d, the Board prohibited the bringing of rags from Italy between that date and November 1st. This latter prohibition was later extended till April 1st, 1887, and during the autumn a similar prohibition was placed on the bringing of rags into England from Austria-Hungary, this restriction also to remain in force until April 1st, 1887.

Yellow fever prevailed during the first half of the year on the northern shores of South America and in Central America, being at times quite severe in Rio de Janeiro, Bahia, Pernambuco, Guiana, as well as among the British residents of Venezuela and the workmen of the Panama canal. The epidemic in Brazil has served to call renewed attention to the matter of Dr. Freire's inoculation for yellow fever with the *cryptococcus xanthogenicus*. These inoculations have been practised upon a large number of persons, and their protective effect is still *sub-judice*. Dr. Holt, of Louisiana, has asked that a commission be sent to Brazil and also Mexico by the United States government to investigate the subject. Assurance has been given that, should such a commission go out, the fullest opportunity will be granted by Dr. Freire for studying his methods and their results. It is certainly of great importance that the truth in this matter be sifted, though it is but fair to say that bacteriologists look askance at the claim, and are prepared to see it relegated to the same limbo as that of Ferrán.

A Norwegian vessel from Aspinwall brought six cases of yellow fever into New Orleans in August, but prompt sanitary measures were taken and the disease did not extend. An epidemic, which led to a heated discussion among local sanitarians and clinicians, occurred at Biloxi, Mississippi, a small town on the gulf coast. It began in August with two or three deaths. An investigation by the Louisiana Health Board made it appear to be yellow fever, and the place was quarantined. The local physicians denied this diagnosis, and called in a surgeon of the United States Marine Hospital Service, who supported their views. The quarantine was then raised, amid maledictions from the citizens that it had been imposed. The disease continued in moderate severity till fifty cases, with fifteen or twenty deaths occurred, and the quarantine was again imposed by the Louisiana Board. The disease finally ceased, and the controversy as to its nature remains unsettled.

Massachusetts has during the year, by a righteous divorce of an unnatural alliance, regained once more a separate State Board of Health. The act was recommended by Governor Robinson in his annual message in January, and passed through both legislative houses, safely evading all the snares of the adversary. On May 19th, the governor sent in the names of seven gentlemen to constitute this Board. They were at once confirmed and have since then exercised the functions which had for the last seven years been in a state of more or less desuetude, —"innocuous desuetude," we fear it can hardly be called.

On March 24th, the corner-stone of the conjoint Examination Hall of the corporations of the Royal Colleges of Physicians and of Surgeons on the Thames embankment, was laid by Queen Victoria with great ceremony and in the presence of a very distinguished company. The new building is to be a most spacious and elegant one, one hundred and fifty feet square and five stories in height, with every requirement for technical work.

Among the regular, endowed medical lecture courses of the year in England and this country we note the following:—

The Erasmus Wilson Lectures on "Evolution in Pathology" were delivered before the Royal College of Surgeons of England, by J. Bland Sutton, F.R.C.S.;

the Gulstonian Lectures on "Spasm in Chronic Nerve Disease" were delivered before the Royal College of Physicians, by Seymour J. Sharkey, M.B., F.R.C.P.; the Croonian Lectures on "Some Points in the Pathology of Rheumatism, Gout, and Diabetes" were delivered before the Royal College of Physicians, by P. W. Latham, M.A., M.D., F.R.C.P.; the Lumleian Lectures were on the "Electrical Conditions of the Human Body" and were given by William H. Stone, M.D., M.R.C.P.; the Cartwright Lectures were delivered before the Association of the Alumni of the College of Physicians and Surgeons of New York, beginning March 23d, by William Osler, M.D., Professor of Clinical Medicine in the University of Pennsylvania; the Ingleby Lectures on "Some Functional Disorders of Females" were delivered at Queen's College, Birmingham, by Willoughby Francis Wade, F.R.C.P.; the Bowman Lecture was delivered before the Ophthalmological Society of the United Kingdom, by Wilhelm von Zehender, Professor of Ophthalmology in the University of Rostock, and was on the subject of "Parasitic Diseases of the Eye."

The year 1886, which has made such signal havoc in the higher ranks of political life — in the death of the vice-president of the United States, of an ex-president and of three prominent candidates for that high office, as well as of the late unsuccessful candidate for the vice-presidency — has not spared the medical profession, some of whose brightest lights have gone out. Among the most widely-known persons who have died, we mention a few:—

John C. Draper, M.D., LL.D., died the last of December, 1885, of pneumonia, at the age of fifty. He was for thirteen years analytical chemist in the New York University. In 1860 he was appointed Professor of Chemistry in the Cooper Institute but relinquished the position after two or three years to become a surgeon in the army. He was the author of several chemical text-books as well as of a work on Medical Physics. He was son of Prof. John W. Draper and brother of Dr. Henry Draper.

Dr. Amédie Dechambre, of Paris, editor of the *Gazette Hebomadaire*, and one of the oldest medical editors of France, died early in the year.

Dr. Jules Guérin, one of the oldest French physicians, founder of the *Gazette Médicale* of Paris, a vigorous participator in the debates of the Academy of Medicine, and a very voluminous writer, died January 25th, at the age of eighty-six.

Alfred C. Post, M.D., LL.D., one of the oldest and most distinguished surgeons of New York city, died February 7th at the age of eighty-one, having been in continuous surgical practice for fifty-seven years, and continuing it up to within a week of his death. He had been surgeon to the New York Hospital, and more recently to the St. Luke's and Presbyterian Hospitals. He was one of the founders of the Medical Department of the University of the city of New York and was at the time of his death President of the Faculty and Emeritus Professor of Clinical Surgery in that institution. He had been connected with many of the chief medical societies of this and other countries.

John Cooper Forster, M.B., F.R.C.S., died March 2d, at the age of sixty-two. He had retired from professional work a few months previously, leaving the highest position in his profession, namely, the Presidency of the Royal College of Surgeons of England. Having been the assistant surgeon to Guy's Hospital until the retirement of Mr. Hilton in 1870, he was that year made surgeon to the hospital. He performed the first gastrotomy in England in 1857, upon a patient with cancer of the œsophagus, and was one of the earliest to try the Listerian method, although he afterwards abandoned the system in its details. He furnished many valuable articles in the Guy's Hospital Reports and was the author of a book on the Surgical Diseases of Children.

Dr. Gaspar Griswold, M.D., F.R.C.S., a graduate at Bellevue Hospital, demonstrator of anatomy at Bellevue and a professional associate with Dr. Fordyce Barker, died suddenly March 4th, at the age of twenty-nine.

Samuel Oakley Vander Poel, M.D., LL.D., of New York, surgeon-general of New York State during the war, where his duties were most responsible and arduous, Health officer of the port of New York from 1872–1880, professor of Theory and Practice in the Albany Medical College and of Public Hygiene in the Medical Department of the University of New York, died March 12, at the age of sixty-two. He had been president of the New York State Medical Society and a member of the International Medical Congress at Copenhagen in 1884.

Austin Flint, M.D., LL.D., of New York, died March 13th, at the age of seventy-four. Little need be said to remind our readers of the results accomplished by the ability and industry of this eminent physician. His works on Phthisis, on Auscultation and Percussion and his classical Principles and Practice of Medicine are in the libraries of most of the physicians who use the English tongue. He had been invited to deliver the address in Medicine before the British Medical Association, and though the address had fortunately been prepared and has since been published, the honor of appearing in behalf of American Medicine on that occasion was transferred to Dr. Billings. Dr. Flint was, as is well known, the president elect of the International Medical Congress of 1887.

Dr. Santesson, of Stockholm, a famous anatomist and surgeon and professor emeritus in the University, died at the age of sixty-four.

Dr. Bochefontaine, chief of the Laboratory of the Faculty of Medicine of Paris, died in the spring. He was an active opponent of Pasteur and Koch and showed his faith by his works, in swallowing a dose of cholera bacilli last year.

Legrand du Saulle, physician to the Salpêtrière, and author of a number of monographs on Toxicology and Forensic medicine, died May 6th, at the age of fifty-five.

Walter Moxon, M.D., F.R.C.P., one of the most prominent English pathologists, died suddenly July 21st, at the age of fifty. He showed wonderful promise while a student at Guy's Hospital, taking many prizes, and at his graduation, honors in every subject. He began his teaching career as Demonstrator of Anatomy in the Medical School of Guy's, and five years later succeeded Dr. Wilks in the pathological department. After several years' work in this department he was appointed to the joint lectureship on medicine. Many of his most important productions are published in the Guy's Hospital reports and include a wide range of important subjects, all of which are treated with the precision of expression and definiteness of knowledge which characterized his earlier anatomical work.

Alfred S. Purdy, A.M., M.D., an old practitioner of New York, died July 23d, in the seventy-ninth year of his age, and the fifty-sixth of his practice.

Frank Hastings Hamilton, M.D., LL.D., died in New York, August 11th, at the age of seventy-three. In conjunction with Dr. Austin Flint he bore an important part in the establishment of the Medical Department of the University of Buffalo. Removing to New York in 1862 he became professor of surgery at the Bellevue Hospital Medical College, which position he held for thirteen years. He remained surgeon to this hospital to the time of his death. During the War of the Rebellion he served in the army and became medical inspector. He was one of the consultants in the case of President Garfield. His monumental work on "Fractures and Dislocations" passed through several editions and was translated into more than one European language. Besides this he wrote text-books on other subjects, including one on military surgery and another on general surgery. The death of Gross, Post and Hamilton, within a year of each other leaves a void in the ranks of American surgery, hard to be filled.

Charles Chadwick, M.D., F.R.C.P., formerly President of the British Medical Association, and always prominent in its counsels, a leading physician of Leeds and connected with the hospitals and the medical school of that city, died suddenly August 30th, of acetonæmia, at the age of seventy-one.

James Goodchild Wakley, M.D., M.R.C.S., editor of the *London Lancet*, and son of the founder of that journal, died August 30th, of epithelioma of the tongue, at the age of sixty. His official position naturally made him known in matters of public medicine, and he was a most constant and generous helper of all worthy objects of benevolence. He played an important part in the foundation of the Hospital Fund to which he twice gave the sum of £1,000. He left on record a strong testimony of his faith in the Christian religion, and in the hearts of the poor of the great metropolis a lasting remembrance of his practical applications of those principles. It may be remarked, in this connection, that the Hospital Saturday and Sunday Funds in London, amounted this year to the unprecedented sum of $200,000.

Dr. Bernard von Gudden, perhaps the most distinguished alienist of the day, and director of the Munich Insane Asylum, was killed by the insane King Ludwig, of Bavaria, upon whom he was in attendance. He was sixty-two years of age. It is said that he had on hand more than a hundred brains, to which he intended to devote his careful study with the hope of elucidating certain questions in cerebral pathology.

Dr. Hermann Maas, professor of surgery in Würzburg died at the age of forty-four.

Joseph Samson Gamgee, M.R.C.S., a well-known surgeon of Birmingham, England, died September 18th, in his fifty-ninth year. He was a popular and successful teacher of clinical surgery in Queen's College, and a valued member of the staff of Queen's Hospital, besides being the author of many publications and the inventor of several surgical appliances.

Dr. Wm. Henry Dudley, President of the Collegiate Department of the Long Island College Hospital, died in Brooklyn, October 8th, at the age of seventy-five. He was one of the chief founders of the Long Island College Hospital in 1859, and has ever since contributed liberally in money and exertion to its successful development He was also a physician to St. John's Hospital.

Frederick John Farre, M.D., F.R.C.P., and Arthur Wynn Williams, F.R.C.P., the one Senior Physician to St. Bartholomew's Hospital, and the other Consulting Physician to the Samaritan Free Hospital, died in November, at the ages respectively of eighty-two and sixty-seven.

Paul Bert, eminent as a physiologist, died November 13th, at the age of sixty-three, from dysentery, at Tonquin, where he had resided as President General since April last. His earlier and more peaceful triumphs were at the Faculty of Sciences at Bordeaux, and at the Sorbonne, Paris, where he collaborated with and afterwards succeeded Claude Bernard. Under Gambetta in 1881, he was made minister of Public Instruction. His later years were much given up to political contests, in which he was a hard fighter.

John P. Gray, M.D., LL.D., superintendent of the State Lunatic Asylum, at Utica, New York, died November 29, 1886, at the age of sixty-one. He served as assistant physician in that institution from 1851 till 1854, when at the age of 28 he was made its medical superintendent. In the same year he began to edit the *American Journal of Insanity*. Beside this work he wrote many monographs and made many addresses, among them one before the State Medical society, in 1871, relative to the "Dependence of Insanity on Physical Disease;" and in 1873, before the American association of medical superintendents of hospitals for the insane, an address on the "Pathology of Insanity." Appointed in 1864 professor of psychological medicine and medical jurisprudence in Bellevue Medical College, he gave a course of lectures that impressed the students and faculty, and drew in auditors from the outside; a discourse giving a "General View of Insanity," was published, and serves to show the

breadth and thoroughness of the discussion. The State Medical Society summoned him again to speak before it, in 1884, when he presented "Thoughts on the Causation of Insanity." The Albany Medical College in 1876, appointed him its professor of pyschological medicine, and there as well as at Bellevue, he continued his lectures, until 1882. Other productions which have been published, are: "Mental Hygiene," delivered in 1876 in Philadelphia before the International Medical Congress (of which he was president of the psychological section;) "Pathological Researches," 1877; "Abstract of the laws of New York relative to Insanity," before the association of medical editors, 1878; an elaborate discourse on "Suicide," delivered at Bellevue Hospital Medical College, 1878; "Hyoscyamia in Insanity," before the medical society of New York, 1880. His address on "Heredity" in 1884, delivered as president of the American Association of Superintendents in Philadelphia, exhibits his vigor of thought and force of style in their excellence. Elected again as president of the State Medical Society, his address in 1885 treated in a very liberal spirit of the "Relations of the State to medical science." A lecture, on "Insanity and some of its preventable causes," delivered before the Utica Mechanics' Association in 1885, while popular was full of sense and science. He was shot in 1882 by an insane man and never recovered from the nervous shock of the wound which finally led to his untimely death.

Dr. Marcovici, Professor of Clinical Medicine and Dermatology in the Faculty of Medicine of Bucharest, died at the age of fifty. He achieved considerable distinction as interne at the Bicêtre, and on returning to his country, made some useful contributions to medical literature. He had taken an important part in several medical congresses.

Dr. Norman Chevers, C.I.E., whose death occurred on December 2d, was Secretary to the Medical Board at Calcutta, and subsequently became principal and first physician, and professor of medicine of the medical college of that place, where he lived for about quarter of a century. He was a member of the Medical Committee appointed by the Secretary of State for India to inquire into Professor Koch's discovery in connection with the prevalence of cholera.

NECROLOGY OF THE MASSACHUSETTS MEDICAL SOCIETY FOR 1886.

We include three deaths which occurred at the end of last year, too late to be included in our necrology for 1885:

Alfred Wood, M.D., of Taunton, died December 28, 1885, aged eighty-nine.

Nathan Pike Brownell, M.D., died in South Scituate, December 29, 1885, aged sixty.

Rufus Woodward, M.D., died in Worcester, December 30, 1885, aged sixty-six years.

James Henry Whittemore, M.D., died in Boston, January 6, 1886, aged forty-six.

Ebenezer Coolidge Richardson, M.D., of Ware, died January 10, 1886, aged sixty-five.

William Henry Haston Shepard, M.D., died at Westminster, February 7, 1886, aged forty-four.

David Fogg Drew, M.D., died at Lynn, February 13, 1886, aged sixty-six.

Joseph Haven Smith, M.D., died at Lowell, February 25, 1886, aged eighty.

John McLean Hayward, M.D., died at Wayland, March 9, 1886, aged forty-eight.

Austin Flint, M.D., Honorary M.M.S.S., died in New York, N. Y., March 13, 1886, aged seventy-three.

Clinton Joseph Ricker, M.D., died at Chatham, Mass., March 15, 1886, aged thirty-nine.

Robert Mendum Otis, M.D., died at Roslindale, March 19, 1886, aged forty-two.

Levi Goodenough, M.D., died at South Sudbury, April 3, 1886, aged eighty-two.

George Amory Bethune, M.D., died in Boston, April 5, 1886, aged seventy-three.

Anderson Dana Dyer, M.D., died at Brandon, Vt., April 12, 1886, aged twenty-seven.

George Washington Pierce, M.D., died at Leominster, May 1, 1886, aged sixty-six.

David Parker, M.D., died at Gardner, May 8, 1886, aged eighty-four.

Horatio Gilead Morse, M.D., died at Roxbury, May 12, 1886, aged sixty-nine.

Eugene Stephen Yates, M.D., died in Lawrence, July 28, 1886.

Charles Dudley Homans, M.D., of Boston, died at Bar Harbor, Me., September 2, 1886, aged sixty years.

John Lang Bennett, M.D., died at Wollaston, September 13, 1886, aged thirty-five.

Joseph Sampson Gamgee, F.R.S. Ed., M.M.S.S. Hon., died in Birmingham, Eng., September 18, 1886, aged fifty-eight.

John Sherman Emerson, M.D., died in Lynn, September 23, aged fifty-four.

Alley Talbot Wakefield, M.D., died in Cambridge, October 18, 1886, aged thirty-one.

Frank Albert Durgin, M.D., died in Salem, November 4, 1886, aged thirty-one.

Frederic Davis Brown, M.D., died in Webster, November 8, 1886, aged sixty-two.

Francis Patrick Scully, M.D., died in Portland, Me., November 12, 1886, aged thirty-four.

Luther Parks, M.D., died in Pau, France, November 19, 1886, aged sixty-three.

Josiah Sturtevant Hammond, M.D., died at Plympton, November 28, 1886, aged seventy-six.

Frederic Clinton Woodbury, M.D., died in Boston, December 4, 1886, aged twenty-five.

Willard William Codman, M.D., died in Boston, December 22, 1886.

MEDICAL NOTES.

— An important addition to the Topeka Insane Asylum, Kansas, has just been completed. It is a hall for dramatic, musical and other entertainments, is 80 by 50 feet, has a stage and accessories, is well

lighted and ventilated, and will seat six hundred persons. It was appropriately dedicated December 11th.

NEW YORK.

— At a meeting of the Board of Health, held December 23d, Dr. Day, Sanitary Superintendent, made a report in regard to the investigation of a complaint recently received by the Board from a resident of one of the uptown streets, in which the New York Steam Heating Company have been making excavations for a trench in which to lay its pipes. In the complaint it was stated that the exhalations from the excavations were offensive and injurious to health, and that in some places the gas-pipes had been injured, and gas allowed to escape. Dr. Day reported that he had inspected the locality named, and that the work, which was still unfinished, had been commenced as long ago as November 15th, and that since that time members of three families in the neighborhood had suffered from malarial symptoms sufficiently severe to require medical attendance. In consequence, Dr. Day made a recommendation that in the future the Steam Heating Company should be required to disinfect the earth as it is thrown out from the trench, and this was adopted by the Board.

REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 18, 1886.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,507: under five years of age 958; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 462, consumption 398, lung diseases 374, diphtheria and croup 186, measles 114, typhoid fever 57, diarrhœal diseases 44, malarial fevers 15, scarlet fever 12, cerebro-spinal meningitis 11, whooping-cough 10, erysipelas nine, puerperal fever four. From diarrhœal diseases, New York 21, New Orleans four, Brooklyn, Boston, and Baltimore three each, Cincinnati, Charleston and Lowell two each, Nashville, Fall River, Springfield and Northampton one each. From malarial fever, Brooklyn six, New York four, Baltimore and New Orleans two each, Charleston one. From scarlet fever, Brooklyn six, New York five, Pittsburgh one. From cerebro-spinal meningitis, New York six, Baltimore two, Cincinnati, Lowell and Springfield one each. From whooping-cough, Brooklyn four, New York and Boston two each, Pittsburgh and Cambridge one each. From erysipelas, Brooklyn and New York three each, Pittsburgh two, Fall River one. From puerperal fever, Baltimore two, New York and Boston one each. Pittsburgh reports one case of small-pox.

In the 22 cities and greater towns of Massachusetts with a population of 970,769 (population of the State 1,941,465) the total death-rate for the week was 21.05 against 23.05 and 18.14 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,093,817, for the week ending December 4th the death-rate was 21.0. Deaths reported 3,052: infants under one year of age 817; measles 134, scarlet fever 70, whooping-cough 61, diarrhœal diseases 46, fever 36, diphtheria 32.

The death-rates ranged from 14.3 in Brighton to 32.1 in Oldham; Birkenhead 14.2; Birmingham 17.5; Bradford 20.2; Halifax 23.3; Hull 21.8; Leeds 26.0; Leicester 18.3; Liverpool 22.5; London 20.3; Manchester 26.6; Nottingham 16.5; Sheffield 18.1.

In Edinburgh 21.3; Glasgow 27.4; Dublin 28.1.

For the week ending November 4th, in the Swiss towns, there were 32 deaths from consumption, lung diseases 16, diarrhœal diseases nine, diphtheria and croup four, scarlet fever three, measles, erysipelas and typhoid fever each two, whooping-cough one.

The death-rates were: at Zurich 13.4; Geneva 17.2; Basle 18.5; Berne 31.0.

The meteorological record for the week ending December 18, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps: —

Week ending Saturday, Dec. 18, 1886.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 18, 1886, TO DECEMBER 24, 1886.

FORWOOD, W. H., major and surgeon. Granted leave of absence for one month. S. O. 129, Department of Dakota, December 16, 1886.

LAUDERDALE, J. V., captain and assistant surgeon. Ordered from Fort Concho to Fort Clark, Tex. S. O. 174, Department of Texas, December 16, 1886.

EVERTS, EDWARD, first lieutenant and assistant surgeon. Ordered from Fort Grant to Fort Apache.

MASON, CHAS. F., first lieutenant and assistant surgeon. Ordered from Fort Huachuca to Fort McDowell.

BANISTER, W. B., first lieutenant and assistant surgeon. Ordered from Fort Wingate to Fort Lowell.

DIETZ, W. D., first lieutenant and assistant surgeon. Ordered from Fort Stanton to Fort Bayard. S. O. 136, Department of Arizona, December 16, 1886.

POLHUMUS, A. S., first lieutenant and assistant surgeon. Ordered for duty as post-surgeon at Fort Gaston, Cal., relieving

RAYMOND, H. L., first lieutenant and assistant surgeon. Ordered for duty at Angel Island, Cal. S. O. 123, Department of California, December 13, 1886.

ANDERSON, C. L. G., first lieutenant and assistant surgeon. Assigned, temporarily, to duty at Whipple Barracks, Ariz. S. O. 132, Department of Arizona, December 7, 1886.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE FOR THE THREE WEEKS ENDING DECEMBER 18, 1886.

BANKS, C. E., passed assistant surgeon. Granted leave of absence for twelve days, December 16, 1886.

CARRINGTON, P. M., assistant surgeon. Granted leave of absence for fifteen days, December 6, 1886.
